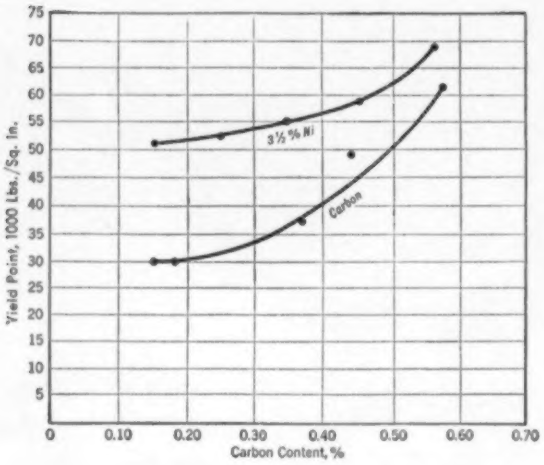
NICKEL ALLOY STEEL FORGINGS

Larger than 4 inches in diameter or equivalent section

Uses

Forged alloy steels are employed for large shafts, turbine motor and generator drums, gears, flywheels, pressure chambers, die blocks, Diesel engine parts, locomotive forgings, axles, extrusion dies, rolls and parts of steel mills, steam-hammer piston rods, hydraulic press rams, etc. In general, large forgings of this kind are used for parts of heavy machinery where strength and toughness, high impact and fatigue resistance and reliability are required.



Comparison of Normalized Nickel Steel and Carbon Steel Forgings

Properties

Large forgings vary in shape and in size, and to attempt roughly to classify them by size necessarily results in generalization The purchaser may reasonably expect higher properties than are guaranteed, unless his forgings are extreme in size or intricacy. Table I gives, for large nickel alloy steel forgings, specifications which are considered standard; the properties which may reasonably be expected from what might be called the "average" of each group; and concrete examples of properties which have actually been obtained in practice.

Type	Carbon	Manganese	Nickel	Chromium	Molybdenum	Vanadium	Remarks
3% Nickel	0.13-0.50	0.40-0.80	Min. 3.00	..	..	..	General structural, for strength and toughness.
2.5% Nickel	0.18-0.35	0.60-0.90	Min. 2.50	..	..	..	Intended for normalized forgings.
Nickel-Chromium	0.25-0.45	0.40-0.80	2.75-3.50	0.60-0.95	..	..	Heat treated usually by quench and temper.
Nickel-Chromium	0.28-0.42	0.40-0.70	Min. 1.25	Min. 0.70	..	..	Slightly lower properties.
Nickel-Chromium	0.25-0.50	0.40-0.80	2.75-3.50	1.25-1.75	..	..	For higher tensile values.
Nickel-Chromium	0.20-0.45	0.40-0.80	Min. 4.50	1.25-1.75	..	..	"Krupp Analysis" for very high tensile values.
Nickel-Molybdenum	0.25-0.40	0.60-0.90	2.00-3.00	..	Min. 0.30	..	Suitable for normalizing or quenching.
Nickel-Chromium-Molybdenum	0.25-0.40	0.40-0.80	2.00-3.00	0.60-0.95	0.30-0.60	..	Suitable for normalizing or quenching.
Nickel-Vanadium	0.18-0.45	0.60-0.90	1.75-2.25	..	..	Min. 0.15	Suitable for normalizing or quenching.
Nickel-Chromium-Molybdenum-Vanadium	0.25-0.70	0.40-0.80	1.25-1.75	0.50-1.00	0.20-0.30	Min. 0.15	High values.

Phosphorus and Sulphur usually specified under 0.045%

Table II. Nickel Alloy Forging Steels

Manufacture

It is usually specified that the steel may be made by any process—acid or basic open-hearth, acid or basic electric furnace. Each process has some advantages and there is not an overwhelming argument advanced for any one. The electric furnace, however, does not contribute a large tonnage, due to the comparatively small size of most electric furnaces.

Whenever possible, forgings should be axially bored. There is a fourfold reason for this. The physical properties are benefited by the increased rate of cooling; the material at the axis is not particularly valuable from an engineering standpoint as the stresses are lowest here; the metal which is inherently the poorest is removed and the resulting bore affords an opportunity for internal inspection which is very desirable.

Heat Treatment

All large forgings should be heat treated before delivery. The treatments used are the three standard ones of annealing, normalizing and quenching and tempering, but it is imperative that consideration be given to the masses involved and stresses set up. For very large forgings, say forty inches in diameter or equivalent section, the normalizing treatment is generally the only one used. To break up ingotism the heat treater often resorts to a high temperature normalizing treatment, usually between 1800 and 2000 degrees Fahr. and of long duration.

Nickel lowers the critical ranges of the steel to which it is added. This is advantageous as there is less liability to increased grain growth at the lower heating temperatures and also less liability to warpage and internal stresses on quenching. Nickel steels are not injured, but improved, by long soaking in the critical range.

Type	Treatment	Size	Tensile Strength	Elastic Limit	Elongation in 2" Min. %: Inverse Ratio	Elongation in 2" Min. %: Min. %	Reduction of Area: Inverse Ratio	Reduction of Area: Min. %	Reasonable Expectation: Tensile Strength	Reasonable Expectation: Elastic Limit	Reasonable Expectation: Elongation	Reasonable Expectation: Red. of Area

*Table I. Specifications and Properties of Nickel Alloy Steel Forgings**

*Note: In the accompanying table of specifications, certain steels are designated "K," "L" and "M" types. This is in conformance with the specifications for carbon and alloy steel forgings of the American Society for Testing Materials (A18-27). Their compositions are not specified. The required physical properties can be obtained from the nickel-alloy steels listed above.

Sources of Supply

Large nickel alloy steel forgings are regularly produced by leading manufacturers who are ready to assist in the selection of compositions best suited to meet particular requirements. If the improved properties of nickel alloy steel forgings are of interest to you we shall be glad to put you in touch with established sources of supply.

CURRENT METALLURGICAL ABSTRACTS

EDITORIAL COMMENT

Standing Room Only

WITH 400 to 500 in attendance at the annual Opening Meeting of the Metallurgical Advisory Board at Carnegie Tech. in the fall, and "standing room only" available both at the morning "high brow" session and the afternoon steel-making session, industry again showed its interest in the work. There was reason for this attendance, since good work was clearly presented. Herty, Mehl and Krivobok are among our very best speakers on metallurgical subjects, and always present even a complicated subject in the simplest possible terms. Then, too, there is an informality in the presentation of progress reports as contrasted with formal reports of finished investigations, that creates an atmosphere that is pleasing to the audience.

The work reported was an interesting combination of investigations in pure science—on very pure Fe-Mn-C alloys, and on segregation of ferrite and cementite from austenite—with no special or direct commercial aim, and of those in engineering metallurgy—on deterioration of 18-8 at high temperatures and on deoxidation of steel, in which the problems are commercial ones and pressing ones at that, and in which the attack is primarily from the engineering point of view, though it may and does involve going back as far into pure science as may be necessary to bring out the unknown but needed basic information.

It is interesting to note that the pure science work is supported by Carnegie Tech. through its Bureau of Metallurgical Research, the 18-8 work was a by-product of instruction in research methods in the Graduate School, and the deoxidation work is directly supported by industry through the Metallurgical Advisory Board.

This is a sane distribution, since pure research is essentially the duty of educational institutions, instruction should have the balance between pure science and commercial application that was shown in the work on 18-8, and industry ought to handle its own operating problems as is the case in the work on deoxidation.

We were interested when Dr. Johnston read Dr. Bain's suggestions on certain extensions of the work on segregation of cementite and ferrite from austenite that would tie in directly with some commercial problems. He evidently recognizes the attempts of the pure scientist to aim his work at the elucidation of fundamental problems that arise from commercial needs. That the set-up for the work of the Bureau of Metallurgical Research includes people like Dr. Johnston who can and do see the intimate connection between high-brow work and commercial problems, is also just as it should be.

Dr. Speller and the rest of the Metallurgical Advisory Board should be gratified with the progress of Dr. Herty and his associates in 1932. Although working on a reduced budget, without the financial support of, or the use of the facilities of, the Bureau of Mines which they had up to 1932, they produced the usual output both in quantity and quality. Perhaps the most pleasing thing of all was the testimony of several who discussed the reports, that by the use of the deoxidizers advocated by Herty for quality's sake, they had cut their costs.

This fact, plus the interest and enthusiasm shown at the meetings and the dinner which followed augurs well for the continuation of the work, though the work of the Finance Committee is no sinecure just now. However, we may safely class the Physical Chemistry of Steel Making among the outstandingly successful coöperative projects in metallurgical research.

There are other coöperative projects of importance in operation or in prospect, and those interested in them might well study the method of operation that has worked so well in this case.—H. W. GILLETT

READERS' COMMENT

Steel in the Light of the Precipitation Theory

By ALBERT SAUVEUR

I am much gratified that my short article in the August number of "Metals and Alloys" under the title, "Steel in the Light of the Precipitation Theory," should have induced Mr. Roy M. Allen and Messrs. R. G. Guthrie and J. H. Comstock to write the important contributions to the subject published in the October issue under their respective headings: "The Precipitation Theory of Steel Hardness," and "On the Formation of Lamellar Pearlite." The wish that my remarks would result in constructive criticisms has thus been fulfilled, and it is hoped that others will take part in this discussion.

Admitting with Mr. Allen the probability that atomic carbon rather than molecular Fe_3C is in solid solution in γ-iron, I find no great difficulty in conceiving the precipitation of the carbide as immediately following its formation, either leisurely when γ-iron transforms to α-iron on slow cooling at some 700°C. or very rapidly on quenching at some 300°C.

It is indeed interesting that Mr. Allen should revive the diamond theory of the hardening of steel. That under suitable conditions of temperature and pressure diamonds of microscopic size can be produced in highly carbonized alloys can hardly be denied. We have only to recall the work of the great French chemist, Moissan, who in the latter part of the 19th century succeeded in producing some very small diamonds.

The theory was advanced by some that the hardness of quenched steel was due to the presence of numerous fine diamond particles produced in the quenching bath. In his book, "The Metallurgy of Steel," published in 1890, the late Prof. Henry M. Howe refers to this theory in the following words:

> This explanation (the diamond theory), hardly competent to explain a single phenomenon of hardening and utterly incompatible with many of them, merits notice solely because its discussion and even commendation by those who should have gauged it better has given it fictitious value. Briefly sudden cooling has been supposed to harden steel by converting its carbon into diamond. It is certain that hardened steel does not contain diamond, because none is found in the residue from dissolving it, even in dilute acids.

It is evident that as conceived the diamond theory was quite untenable. In those days hardening through the dispersion of a solute in submicroscopic particles had not been suggested. Considered from this new point of view, as Mr. Allen does, the diamond theory assumes a different aspect.

Mr. Allen argues that when austenite transforms, carbon in the form of submicroscopic diamond may be dispersed as well as carbide particles and may contribute to the hardness of quenched steel. Seeing that microscopic diamonds may be obtained in iron-carbon alloys, it would not be justified to claim that submicroscopic diamonds cannot exist. Indeed it is more logical to infer that the microscopic dimension must of necessity be preceded by the submicroscopic dimension, that in the growth of crystals the submicroscopic stage must precede the microscopic stage.

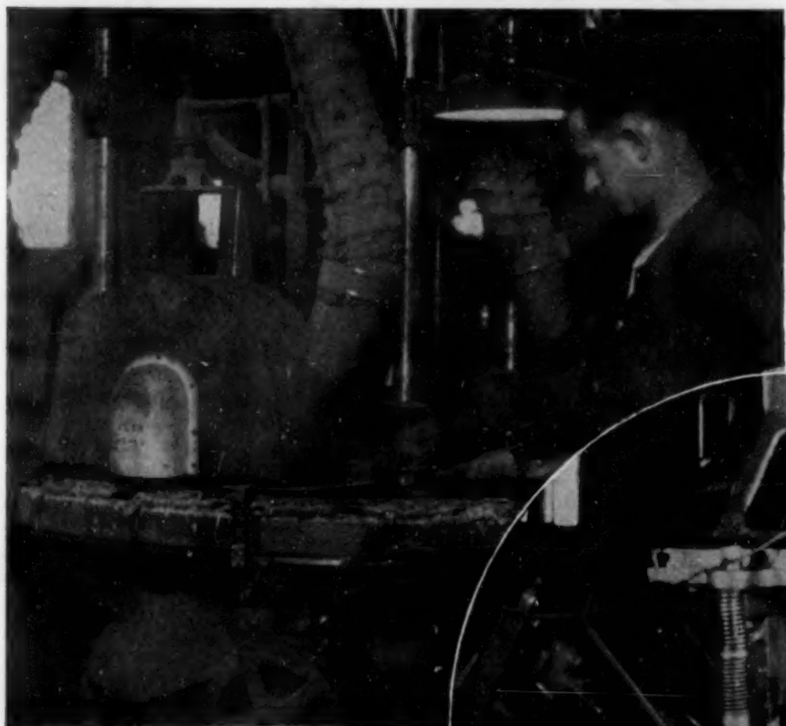
(Continued on Page 269)

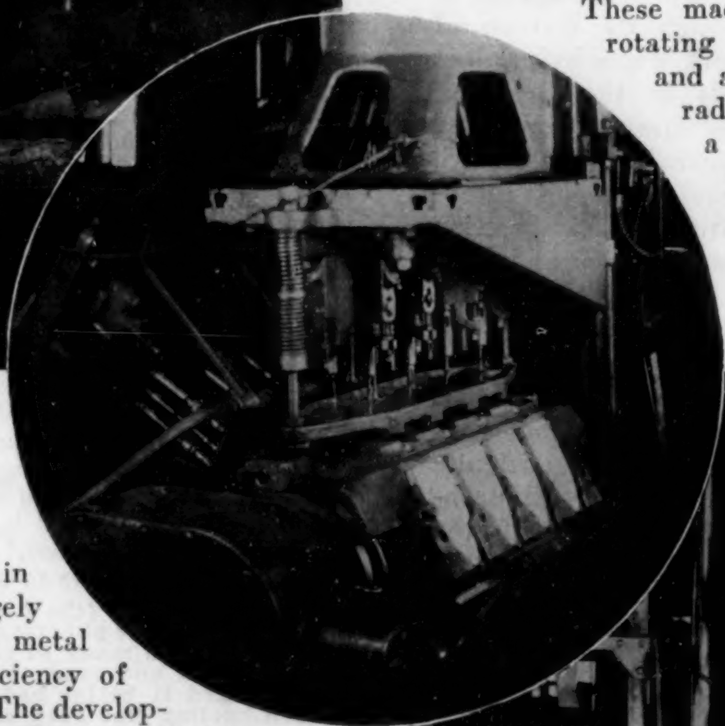
METAL FINISHING

By CLARENCE L.

ORDINARY household irons, although created and devised for strictly useful purposes, are undergoing many changes, and of these changes, style is probably one of the greatest. It seems a far cry from the metal industry to style trends and modes, but the manufacturers have found that women appreciate beauty in irons as well as in clothes and other accessories. Industry in the past has been slow to realize this and the improvements made on the household appliances were, in the main, generally of a scientific nature. An iron was simply an iron—an object of use—and very little concern was given to its appearance.

However, "the old order yieldeth to the new" and now we have beautiful gleaming irons that are a credit to any production put out by manufacturers for practicability





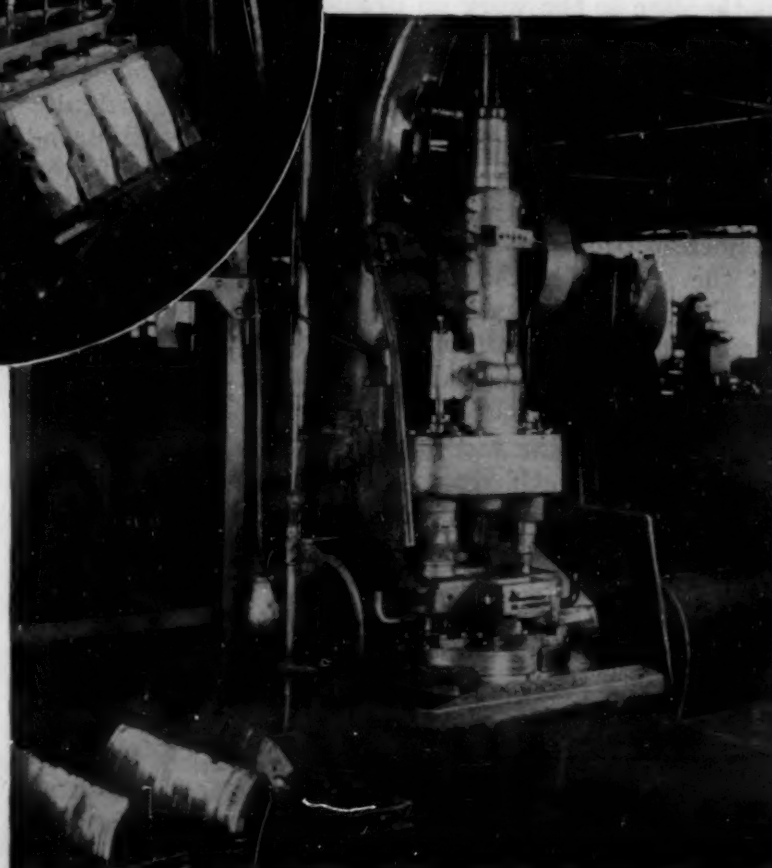


Fig. 1. (above) Four Wheel Automatic Grinding Machine. Fig. 2. (center) Special Drilling & Tapping Machine. Fig. 3. (bottom) Drill & Counter Bore Machine.

as well as beauty. This change in appearance has been made largely by the improved processes in metal finishing and the increased efficiency of automatic finishing equipment. The development of machines and the standardization of processes and material have changed the problem of manufacturing irons from an art to a science with the result that a high quality finish demanded by the public has been reduced to a minimum cost.

The parts requiring finish on the electric iron consist of a cast iron base, a cold rolled steel cover, front and rear handle straps, heel rests, rivets and handle bolts.

The first operation in finishing the iron base is to grind 0.015 inches of material from the top of the base to provide a flat surface for the element and cover on a specially built circular grinding machine. The machine is loaded and unloaded by one operator and the bases pass under four wheels, 9 to 14 inches in diameter, by $5\frac{1}{2}$ inch faces and $1\frac{3}{4}$ inch arbors; one 10 grit, one 24 grit, one 36 grit and one 60 grit. The maximum production of the machine is 30 pieces per minute.

From this operation the bases pass over a conveyor to a special drilling and tapping machine, which drills and taps eight holes at one time and has a maximum capacity of 10 parts per minute. The machine is equipped with a cam operated fixture which is manually loaded and automatically unloaded.

The drilling and tapping operation required considerable development as it was necessary to drill and tap a hole in the iron bases that would have 4 full threads, and not drill through the bases which is less than $\frac{1}{2}$ inch in thickness. High speed steel taps with practically no lead were found satisfactory for the operation. It was necessary for the foundry to reduce their tumbling operations to a minimum to prevent dubbing off of points as this would cause irregular location of bases in the drilling and tapping fixtures. This, in turn, would have made it impossible to automatically grind edges of castings accurately, as the succeeding operations are located from pins that fit in drilled and tapped holes of the iron bases. Next the base is dropped on a belt and is conveyed to tote boxes on gravity conveyor lines which deliver them to a battery of disc grinding machines. These machines are equipped with special rotating fixtures which are cam actuated and are capable of grinding 3 different radii on each side of the iron base at a 58° angle with bases located over pins in drilled and tapped holes. The fixtures also oscillate front to back in order to give even wear on the grinding disc face. The

G of ELECTRIC IRONS

L. VAN DERAU*

first 2 grinders are right and left hand and the disc used is 12 grit, 30 inches in diameter, ¼ inch thick, with an 8 inch opening in the center.

It required a period of almost two years to secure a grinding disc that would grind edges satisfactorily and economically. The first disc used would turn out approximately 500 iron bases, then due to the wearing off of rough surfaces of the disc, and the heat generated, discs would come loose from the steel mounting plate. This was overcome by having the supplier perforate the disc while in the unvitrified state. These perforations had the appearance of a baked waffle and provided space in the disc for iron and abrasive dust. That, in turn, was thrown out by centrifugal force of the rotating disc, after leaving the point of contact of the iron base to the disc, and overcame the abnormal heating of the disc, making it possible to grind from ten to fifteen thousand iron bases on a single disc.

It was also found that it was not practical to grind more than 10 bases per minute as the higher speed would cause small cracks in the edge of iron base, any where from 1/16 to ½ inch in length, that did not show up until the final operation of plating and buffing. These cracks, having the appearance of fine hair lines, were caused by the abnormal heating up of the edge of the iron bases during the grinding operation, and were particularly troublesome on hard chilled castings. It was necessary to have the foundry regulate the time of shaking out the castings from their sand molds to overcome the irregular chilled surfaces of castings. The bases then pass to another right and left hand machine for fine grinding to reduce time of final hand polishing operation on edges. On this machine a 120 grit disc, 30 inches in diameter, ¼ of an inch thick, having an 8 inch center opening is used. Grease stick is used as a polishing lubricant on this disc. The production of these machines is 10 iron bases per minute and from 0.025 to 0.035 inches of iron is removed from the edge on the two grinding operations.

The next operation on the iron base is to grind the back on an 18 inch disc grinding machine which has a special holding fixture. The irons are conveyed from one machine to the other by gravity conveyors throughout all grinding operations. From the grinding operations the base goes to a three station boring machine where the thermostat hole is drilled and counter bored.

The irons are then loaded on a booster and delivered to the loading end of a base bottom grinding machine of the 10 wheel tandem type which has a capacity of 30 pieces per minute. Each grinding or polishing wheel is driven by its own individual motor of from 7½ to 10 horsepower. The pressure and amount of cut of the wheel on the iron base is regulated by spring tension and individual ammeters connected to each motor. The iron bases are loaded on an 8 inch belt equipped with jig attachments and pass under four 10 grit wheels, two 24 grit wheels, two 36 grit wheels and two 60 grit wheels. The wheels are of silicon carbide and bakelite types, and range in size from 14 inches to 9 inches in diameter. They have a 5½ inch face and a 1¾ inch arbor hole. This grinding operation removes from .025 to .035 inches of cast iron from the bottom of the iron bases.

Several thousand dollars was spent in developing grinding and polishing wheels for this machine for grind-

ing and polishing iron bases. Machine pressed 10-24 and 36 grit wheels were found very unsatisfactory, and it was necessary for the supplier to make up wheels in which sawdust was mixed with the abrasive and bond and then hand puddled to prevent getting a wheel that was too compact. This type of wheel is very porous after the firing operation, as the sawdust burns out, leaving the wheel in a honeycombed condition; thereby permitting air to circulate through the wheel and overcome the abnormal heating and breaking of grinding wheels. This also overcomes the tendency for grinding wheels to glaze over as the iron and abrasive dust is pressed into the recesses of the wheel, which, in turn, is thrown out by centrifugal force after leaving point of contact of wheel and iron base. The 60 grit Bakelite type of wheel proved far superior to the silicon carbide type of wheel as it left a much finer abrasive mark in the iron casting and did not heat up as much as the silicon carbide type, although it was more expensive.

It was necessary to standardize the grades of the various grit wheels to a range of from K to P of the Norton Company's standard for hardness of wheels. The heating of wheels encountered on this machine are caused by the almost continuous grinding operation; whereas a hand operator is generally off his wheel as much time as he is grinding on the wheel. This idle time permits air cooling of his grinding wheel and is a problem to deal with on almost all continuous automatic grinding machines when using the dry process of grinding.

After the grinding operation the bases are loaded in tote boxes and conveyed around the back of the machine to the loading end. This provides for storage and necessary cooling time between grinding and polishing operations. The wheels are then changed from grinding to compressed canvas polishing wheels which are 16 inches in diameter, $5\frac{1}{2}$ inch face and are set up with emery and glue ranging from 80 grit to 160 grit. Fast cutting artificial grit is used on 80 and 120 grit wheels. The 140 and 160 grits are of the dull cutting Turkish emery, as a fast cutting fine emery required excess buffing to cover wheel marks that would show through in the final buffed iron bases.

Grease stick and 180 grit emery cake are used as polishing compounds. The conveyor belt on the machine is equipped with oscillating fixtures to break up grinding and polishing abrasive marks. After this polishing operation the bases are loaded into tote boxes and conveyed by gravity to the hand polishers who finish the sides and remove sharp edges at the junction of the side and bottom of the base. These operations are performed on compressed canvas wheels set up with 120 to 160 grit emery. The bases are delivered from the hand polishers over gravity conveyors to an inspection station where they are gaged and inspected for defects prior to plating.

Disc type of muslin or canvas polishing wheels were found very unsatisfactory as every ply or section of disc type wheel would show up in the finished iron base, giving the appearance of hills and valleys. It was found

that the compressed canvas type of polishing wheel will remove this defect as the polishing is done on the flat side of the canvas cloth instead of the edges. It was found that the ordinary compressed canvas wheel with side plates on each side, that are commonly used on hand polishing operations or slower types of polishing machines with wheels of smaller width, were not strong enough to stand up in service on this machine, as the wheels would assume a concaved position when in contact with the iron base under the heavy spring pressure, and after leaving the point of contact, it would assume a convexed position, causing the irons to come off the machine with convexed and concaved surfaces. It would also cause the glued segments of the wheel to separate and throw themselves out of the steel retaining plates by centrifugal force. This trouble was overcome by having the supplier of this type of wheel reinforce the center face of the wheel with two additional steel plates. This reinforcement made the wheels cost three times as much, but proved to be more economical as they will last several years in service, against a few hours for the standard type.

The physical and chemical tests for the iron base castings worked to by the foundry are:

Physical

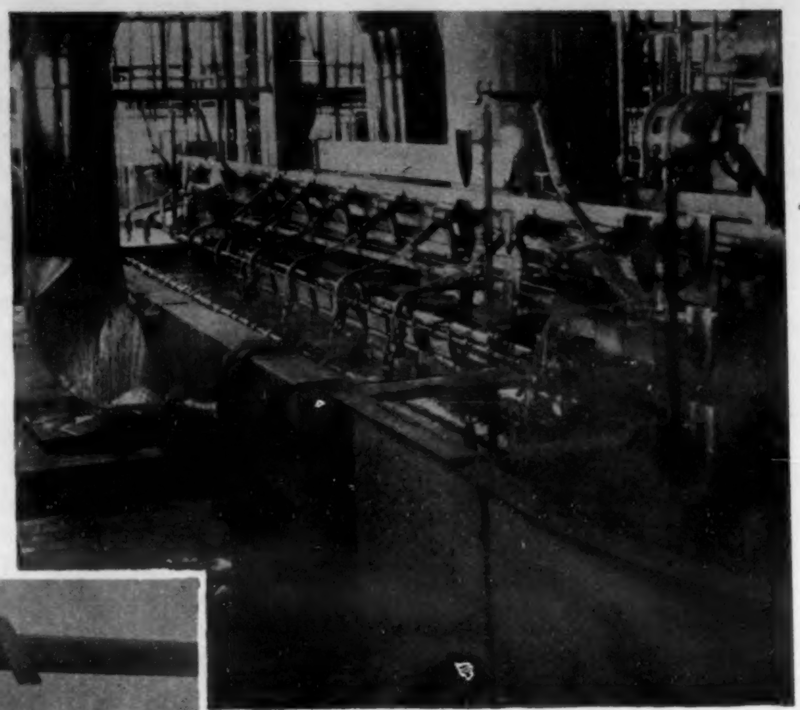
Transverse 2930 lbs. on 1.253" diameter bars

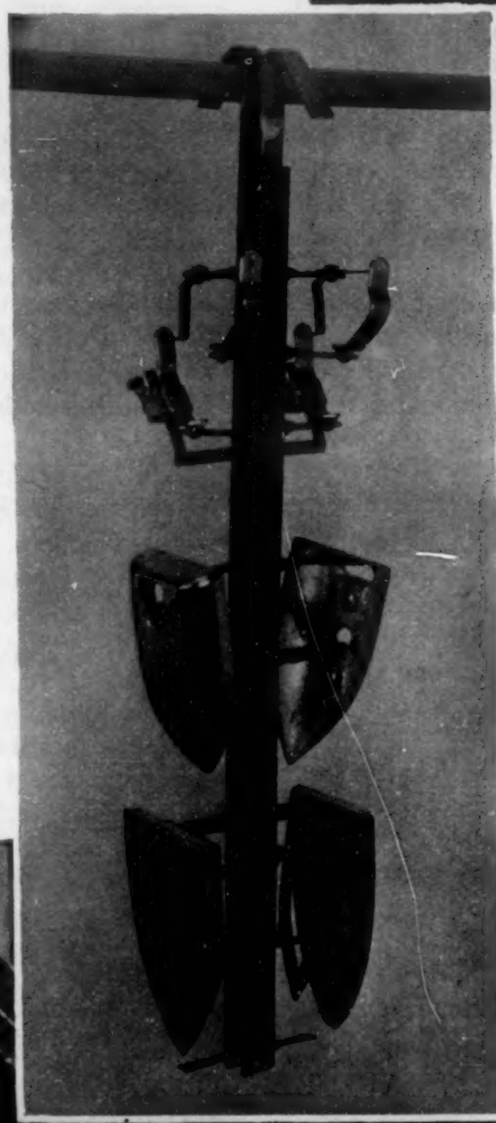
Chemical

Silicon	2.46
Sulphur	.082
Phosphorus	.53
Manganese	.57
Carbon	.48
Graphitic Carbon	3.09
Total Carbon	3.57

The covers which are made of deep drawing, cold rolled steel are of the following physical characteristics:

Olsen .440 - .460
Rockwell B 50 - B 55





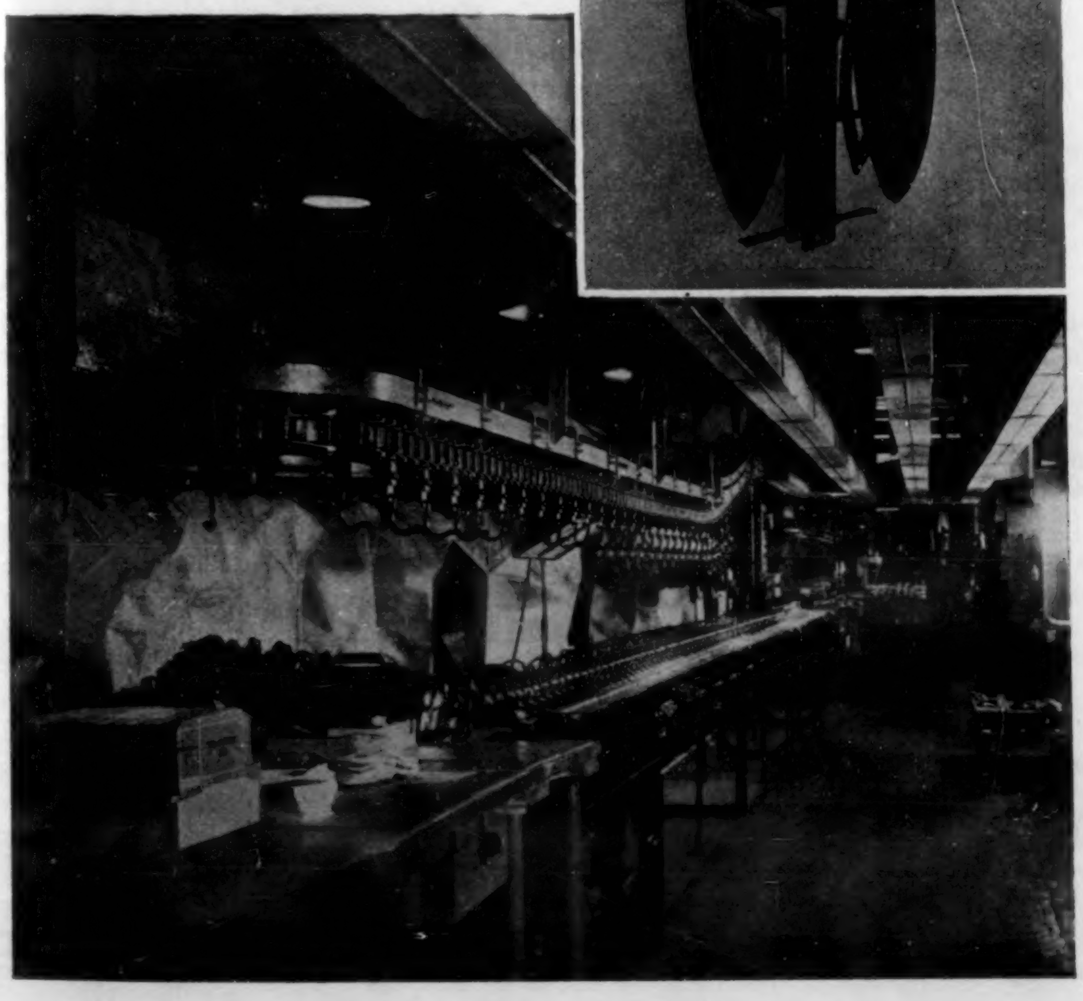


Fig. 10. (above) Automatic Chromium Plating Machine. Fig. 11. (center) Chromium Plating Rack. Fig. 12. (bottom) Iron Assembly Conveyor.

Elongation on 5" long, ¾" wide—
Straight specimen
Longitudinal Minimum 28%
Transverse Minimum 24%

They are first blanked in a die and then formed in a 100 ton draw press. In one operation this press runs at a speed of 20 strokes per minute and is equipped with air cushions and a delivery conveyor belt that takes the covers to the trimming press. The covers are trimmed in a shimmy die. After the trimming operation, handle strap and clamping bolt holes are pierced and heat graduations for the thermostat control are stencilled in a compound die. Then the covers are loaded into tote boxes and delivered by conveyor to hand polishers who polish them on a compressed canvas wheel set up with 160 Turkish emery and glue. They are then brushed on a circular tampico brush using 180 emery cake as a polishing compound in order to remove abrasive scratches. After polishing, the covers are delivered by gravity conveyor to an inspection station where they are inspected for material and polishing defects prior to the plating operation.

As there is always one side of a sheet of cold rolled steel more free from pits and material defects than the other side of the steel, sheets of steel are inspected by the incoming raw material inspector and striped, using a tube approximately 10 inches long, ½ inch in diameter, with a felt cork inserted in lower end and regular cork in top which is filled with a dye solution made up to the following formula:

Lacquer Thinner	75%
Clear Lacquer	15%
Aniline Dye	10%

Various colors indicate the different suppliers, leaving red aniline

color as a mark on questionable steel. This stripe is put on by the incoming raw material inspector by simply drawing his tube of dye from end to end on the selected good side of the steel. This mark indicates to the press operators the proper side to throw blanking burs and makes it possible to always turn the good side of the steel out where the final high finish is required, and has made it possible, with the aid of careful handling in the press shop, to reduce polishing operations from three wheels to one wheel, and has increased production from 30 pieces per hour to approximately 100 pieces per hour in the polishing operation.

All polishing and grinding wheels used in the preceding finishing operations come from a laboratory controlled glue room equipped with special truing and cleaning machines. 80 pounds of high pressure steam and centrifugal force is used to clean off old heads of glue and emery prior to re-setting wheels with glue and emery.

This method of cleaning, dressing and setting up of polishing wheels has proven very economical as very few polishing wheels are worn out by the polishing operation, but are worn out by the polisher using a file or piece of pipe to remove old heads of emery, glue and polishing grease that penetrate into the fabric of wheel. No polisher can clean a wheel using this method without removing some of the fabric and consequently a working face becomes smaller in diameter and goes to the scrap pile prematurely. However, if high pressure steam is not available, the steam cleaning of wheels will not be satisfactory as low pressure steam contains too large an amount of water and will cause the glued segments or plies of cloth to come apart.

A speed of 2200 r.p.m. has proven satisfactory for wheels ranging in size from 10 inches to 16 inches in diameter. The speed should be increased for wheels of smaller diameter in order to throw off glue, emery and greases to prevent penetration into glued sections of wheels.

Wheels cleaned by the above methods will last from five to ten years in service as against a few weeks or months when set up by the polisher.

Glues ranging in price from $.15 to .30 per pound have been tried out on automatic polishing machines and it is more economical to use a high grade hide and sinew glue, as we have found that on the iron bases as high as 16 wheels set up with cheap glue were required; whereas, from three to five wheels were required to do the same given amount of work using the better grade of glue.

The glue is soaked in a definite amount of water (8 lbs. glue to 11 lbs. of water) for approximately 15 hours after which it is heated in a jacketed steam cooker where it is dissolved and flows into a thermostatically controlled steam heated reservoir at a temperature of 180°F. From this reservoir, glue is drawn off into quart containers and placed in a thermostatically controlled hot water table at a temperature of 170°F. Individual cans of glue and brushes are provided for each of the various grades of emery used. The emery containers are steam heated to eliminate the possibility of the glue being chilled by cold emery.

Large wheels used on automatic polishing machines are set up on a wheel setting machine and all wheels are allowed to dry for a period of not less than 12 hours before using. For difficult polishing operations the wheels are dried in an oven at a temperature of 180°F. for a period of at least 12 hours.

Handle straps and heel rests are made of cold rolled steel in cam actuated dies. They are then delivered by conveyor to the plating department where they are burnished in hard maple lined steel burnishing barrels. The barrels are loaded with parts, together with 1/8 inch steel balls and 3 pounds of neutral soap, and burnished for a period of 12 hours.

All of the various parts to be plated, including the polished bases and covers, and the burnished handle straps and heel rests are racked on their respective racks. They are then cleaned in an emulsified soap solution which is as follows:

Tri Sodium Phosphate	1.5 oz.
Caustic Soda	1.5 "
Soda Ash	.9 "
Sodium Metasilicate	.84 "
Bentonite Clay	.06 "
Fatty Acid as Soap	.9 "
Rosin	.3 "
Total	6 Oz.
Water	1 Gallon

then given a water rinse and electro-cleaned in an alkaline copper cleaner of the following formula, using 6 volts, direct current for approximately 1 minute:

Tri Sodium Phosphate	2 oz.
Soda Ash	1.4 "
Caustic Soda	.56 "
Powdered Rosin	.02 "
Bentonite Clay	.02 "
Sodium Cyanide	1 "
Copper Cyanide	.5 "
Water	1 Gal.

and rinsed in water and placed in the moving cathode nickel plating tanks where they are allowed to remain until a deposit of .001 inches of nickel is obtained. (This generally requires 1 hour to 1 hour and 15 minutes of time.)

The current density for nickel plating averages 12 amps./ft.^{2} at $3\frac{1}{2}$ volts. The formula for the nickel solution is:

Nickel Ammonium Sulphate	10 Oz.
Nickel Sulphate	10 "
Sodium Chloride	4 "
Boracic Acid	4 "
Magnesium Sulphate	4 "
Water	1 Gal.

The plating processes are laboratory controlled in order to maintain a soft deposit free from pitting and peeling defects suitable for easy buffing and adherent enough to stand up under stencilling operations that are put on the iron cover in the finished state.

The factors of the nickel solution that require accurate control are:

Factors	*Value*	*Analysis*
Ph	Daily	6.2 to 6.4
Nickel Content	3.56 Oz.	Weekly
Chlorides	3.5 to 4 Oz.	Weekly
Boric Acid	3.5 to 4 Oz.	Weekly
Magnesium Sulphate	4 Oz.	Weekly
Water	1 Gal.	

All plating factors such as current density, plating time and temperatures are standardized and placed on master route sheets and in process specifications that covers the operators activities.

A new nickel solution made to the above formula will have a pH of 5.6 to 5.7 and requires ammonia to raise the pH from 6.2 to 6.4, after which a small addition of 30% Hydrogen Peroxide is used daily to maintain an operating pH of 6.2 to 6.4. By accurate controlling the pH values of the nickel solutions daily, it is possible to practically eliminate all pitting and peeling of nickel deposits. The other factors of a nickel solution are not as sensitive and only require weekly analysis and additions of chemicals to bring them back to their original formulas.

99% rolled depolarized nickel anodes are used as a source for replenishing the metallic nickel content of the plating solutions, and even though the depolarized anodes cost approximately 2¢ more per pound, they have proven themselves to be more economical as it is only necessary to filter the plating solutions twice a year as

against filtering monthly when using the other types of anodes.

This means a saving of approximately $4000 on lost solution and filtering labor on eight 1700 gallon tanks per year in addition to a saving not estimated in excess buffing compounds and labor and rejections that would be caused by floating particles of dirt in the plating solution that would settle out of the solution on all parts that would form a shelf or ledge.

After plating, the racked parts are rinsed in cold and hot water and then placed on an unloading conveyor. The plated polished parts are unracked and placed in tote boxes and sent to the buffing department on gravity conveyors where covers are buffed by hand on buffing lathes running at 3400 r.p.m., using 7 sections of 16 inch diameter, 30 ply, 1/4 inch sewed muslin buffs. These buffs are discarded from the cover buffing operation when they reach a diameter of 10 inches as a peripheral speed changes from 14,200 to 8,700, and these smaller sections of buffs can be used on other lines of apparatus.

Bevelled iron base edges are buffed by hand on one side of a d.c. buffing lathe with a selective r.p.m. speed of 1600 to 2400, while the bottom of another base is being buffed on an oscillating type, automatic buffing machine placed on the other side of the lathe and operated by the edge buffing operator.

A combination of loose and sewed buff sections is used on this operation being of the same diameter and used down to the same size as the buff sections used on iron covers. A lower speed lathe was found more desirable as it overcame the tendency to cut through the iron base edges and produces a superior finish on the bottom of the base.

Lime buffing compound is used for buffing and coloring of nickel. The buffed parts are inspected, packed in tote boxes and sent by gravity conveyor to the chromium plating machine. The handle straps and heel rests are unracked and placed in burnishing barrels where they are burnished for one hour to bring out a luster of the nickel. These parts are then sent to the chromium plating machine.

All parts are racked on special racks for chromium plating and are plated on an automatic chromium plating machine. The machine consists of a rotary conveyor with cam operated lifts through a series of tanks. The loading and unloading of the machine takes place at one station requiring one operator.

Parts travel through an alkaline electro cleaner operated at room temperature, a water shower and rinse, and another water shower before entering the chromium solution. After a 3 minute chromium plating period and 2 successive water rinses and a final cold water spray, parts pass through a hot air drying tunnel for approximately 3 minutes. The final rinsing of parts through a cold water shower overcomes water stains on the plated parts.

The parts are then unracked, inspected, packed in tote boxes and dispatched by conveyor to the assembly conveyor.

The cleaner used for chromium plating is of the following formula:

Sodium Metasilicate	2 oz.
Water	1 Gal.

The reason it is run at room temperature is to prevent staining of clean parts when passing out of the electro cleaner into the first water shower, due to the iron base castings absorbing heat, causing the cleaner to dry off during time of transfer.

The formula for chromium solution is:

Chromic Acid	40 oz.
Sulphuric Acid	.40 oz.
Water	1 Gal.

The operating temperature is 135°F. and the current density is approximately 300 amps./ft.^{2} The chromic acid and sulphuric acid content is checked weekly by the chemical laboratory and additions of these 2 ingredients are always governed by chemical analysis.

Iron elements, cords and thermostats are made in their respective detailed assembly groups, feeding up to the main assembly conveyor where they join up with the plated parts for assembly. After assembly they are given a heat test, after which they pass through a cooling tunnel. Irons are removed from the cooling tunnel conveyor and receive a final buffing operation on loose cotton buffs to remove all stains and marks due to handling. After this operation they are placed in their respective cartons and delivered by conveyor to the warehouse.

Readers' Comments, continued from page 263

The fact, however, that minute particles of diamond are probably harder than similar particles of the carbide can hardly be advanced as an argument favoring the precipitation and dispersion of diamond particles rather than of carbide particles in quenching. The hardness resulting from submicroscopic precipitation is not dependent upon the hardness of the precipitant as much as it is upon the fact that by their location and number the precipitated particles effectively interfere with slip.

Admitting the possible formation in the quenching bath of minute diamond particles, are the arguments offered by Mr. Allen sufficiently convincing for the ready acceptance of his theory?

He conceives the possible existence of 3 steps in the formation of the carbide Fe_3C, namely the formation of the diamond phase as the carbon is rejected from the γ solid solution, the transformation of the diamond phase into the graphite (or amorphous) phase and finally the formation of the carbide.

It is interesting to recall that Percy in his great work "Iron and Steel," published in 1864, refers to the possible existence of graphite in quenched steel when he writes:

> In molten, or even in strongly heated solid steel, the carbon is wholly combined, or, possibly, simply dissolved; and by sudden solidification of the metal in the one case, or sudden cooling of it in the other, the whole of the carbon remains diffused through the mass. However, the carbon may have separated notwithstanding, and exist in a state of infinitesimally fine division; and it is conceivable that it may be in the allotropic condition of graphite, and may yet, owing to what I will venture to designate an atomic state of disaggregation, be capable of entering into combination with nascent hydrogen, and what is termed *combined* carbon. Whether this view be correct or not, it is certain that hard and soft steel differ essentially with regard to the mode of existence of the carbon in a mass.

Parenthetically, may we not express our admiration that at so early a date many of the assumptions upon which modern theories are based were familiar to Percy, namely the existence of carbon in a combined and dissolved form (an early conception of solid solutions), the retention by sudden cooling of carbon in a diffused condition and the existence of tensions or stresses in quickly cooled steel.

Mr. Allen's theory is certainly not so simple as the one based solely upon carbide precipitation and unless there are good reasons for abandoning a simple theory in favor of a more complex one, we should not readily do so—we may ask whether the reasons offered by Mr. Allen are sufficiently good.

If submicroscopic diamonds are present in hardened steel, should not their existence be revealed by X-ray diffraction analysis? If particles of diamond and of graphite are present in hardened steel, should not the solution of the steel in boiling nitric acid leave a carbonaceous residue? As to white and dark martensite, might it not be that the latter represents the first step in the formation of carbide particles of microscopic size and possibly for that reason more readily attacked by some etching reagents. It would then be a connecting link between true (white) martensite and troostite.

In regard to Mr. Allen's contention that his theory "fits in with the view that on slow cooling austenite decomposes directly to pearlite," I have on several occasions attempted to explain why I do not believe such view to be correct, and I shall again do so later in this article.

To sum up briefly the theory of the constitution of steel, I have ventured to offer: rapid and intense precipitation of submicroscopic particles of carbide of iron takes place in the quenching bath at some 300°C. when γ-iron transforms into α-iron. This may be described as nearly instantaneous and

Heat Treating Furnace Atmospheres

By SAM TOUR*

Classification of Furnaces:

FURNACES can be classified according to the motion of the atmosphere within the heating chamber as follows:

I. Transient or rapidly moving atmospheres.
   a. Gas-fired furnaces of the hearth or oven type.
   b. Oil-fired furnaces of the hearth or oven type.
   c. Coal-fired furnaces of the hearth or oven type.
   d. Wood-fired furnaces of the hearth or oven type.

II. Quiescent or very slowly moving atmospheres in the work chamber.
   a. Electrically heated furnaces,
      1. Metallic resistor,
      2. Globar resistor,
      3. Carbon plate resistor.
   b. Fuel-fired retort furnaces of the pot, box, assay muffle or closed heating chamber type.

Transient Atmosphere Furnaces:

In the transient atmosphere type of furnace, the atmosphere surrounding the work in the furnace is dependent upon the method by which the furnace is fired. For this reason, the atmosphere around the work cannot be controlled independently of temperature. Every time the ratio of fuel to air being burned is varied, in attempts to control the furnace atmosphere, the thermal efficiency of the fuel combustion is affected. For good efficient combustion of fuel and, therefore, economic and efficient operation of the furnace, the atmosphere within the furnace cannot be widely varied. There are certain limits to the atmosphere which can be obtained in a furnace of this type even though one is to sacrifice efficient combustion.

In a majority of the fuel-fired heat-treating furnaces in use today, combustion is not entirely complete in the combustion chamber. This is especially true when operating with a so-called "neutral atmosphere." In these cases, combustion takes place not only in the combustion chamber, if such a chamber has been incorporated in the furnace when it was constructed, but also in the heating chamber as is evident by the flames seen in this chamber. If flames are present in the heating chamber, combustion is taking place there and obviously combustion has not been complete in the combustion chamber. Also, obviously, if combustion is taking place in the heating chamber, although a soft flame surrounds the work, oxygen is present or combustion would not be supported. The work is, therefore, exposed, when surrounded by a soft flame, to a mixture of air and the combustible gases of the fuel.

Gas analyses made upon quickly cooled gas samples withdrawn from such furnaces in the neighborhood of the work being treated often show oxygen, hydrogen, carbon monoxide and carbon dioxide all present at the same time. Evidently the gases of the atmosphere are not in equilibrium with each other and combustion is proceeding in an attempt to arrive at this equilibrium condition in the gases for the particular temperature.

It is important to consider these combustion reactions which are taking place. In these reactions, nascent or atomic gases are continually being released. Nascent or atomic gases are many times more active than molecular gases and in that state tend to react much more rapidly with the work being heated. These gases tend to cause the work being heated to scale or corrode or carburize or decarburize or be changed in any one or several of these ways.

The atmosphere existing in a transient atmosphere type of furnace is a function of the quantity of air being supplied for the combustion of the fuel. It can be subdivided for consideration into three classes as follows:

1. Insufficient air. Where a very great insufficiency of air is supplied, the fuel tends to crack and deposit carbon and liberate hydrogen. In spite of the carbon deposition on the work, it is often found that the steel will decarburize in such atmospheres. This can be attributed to the very active decarburizing action of hydrogen in moist atmospheres. Under these conditions, steel very seldom scales.
2. Intermediate air supply. Sufficient air supplied to react with all of the carbon in the fuel and the hydrogen in the fuel but not sufficient to burn all of the carbon to carbon dioxide. In this type of atmosphere, there are present, after the reactions are complete, carbon dioxide, carbon monoxide, water vapor and nitrogen. Such an atmosphere may or may not carburize, decarburize or scale steel entirely dependent upon the kind of steel being heat-treated and the temperature of operation.
3. Excess air supply. Here more than sufficient air is supplied to burn all of the carbon in the fuel to carbon dioxide and all of the hydrogen to water vapor. When combustion reactions are complete, the furnace atmosphere consists of surplus unused oxygen, carbon dioxide, water vapor and nitrogen. Such an atmosphere may or may not decarburize or scale steels depending upon the amount of oxygen present, the kind of steel and the temperature of operation.

The important thing to bear in mind in connection with transient atmosphere types of furnaces, however, is that the atmosphere consists to a considerable extent of moist reacting gases which react not only between each other but also with the surface of the steel.

*Vice-President, Lucius Pitken, Inc., New York, N. Y.

Quiescent Atmosphere Furnaces:

In quiescent atmosphere furnaces, the atmosphere is entirely independent of the heat input into the furnace and so can be controlled to a much greater degree than in furnaces of the fuel-fired type with transient atmospheres. The atmosphere is controlled by the admittance or introduction into the heating chamber or across the door or otherwise of various gases or gas mixtures and of various reagents.

Quiescent atmosphere furnaces can be classified according to the atmospheres in them somewhat as follows:

1. Air—20% Oxygen 80% Nitrogen (approx.).
2. Combusted fuel gases.
3. Raw fuel gases.
4. Cracked gases such as "electrolene"—methane plus carbon monoxide plus hydrogen plus nitrogen plus water vapor.
5. Ammonia—Nitriding Furnaces.
6. Nitrogen + Hydrogen — dissociated ammonia.
7. Hydrogen.
8. Vapors of Liquid—
   a. Steam,
   b. Oil,
   c. Methanol.

To cover all of these classes of quiescent atmosphere furnaces in one paper is too large a field so that the balance of this paper will be restricted to a discussion of the class No. 2 indicated above, the combusted fuel gas class of quiescent atmosphere.

Combusted Fuel Gas Atmosphere:

By "combusted fuel gas" is meant a gas mixture resulting from burning of gas and air properly proportioned so that any desired condition can be obtained. Such combusted gases are stable in themselves since they are the products of the reaction of combustion leading towards equilibrium. Such gas atmospheres are, therefore, in themselves free of reacting gases or nascent gases.

A combusted fuel gas, or in other words the product of combustion of a fuel gas (fuel gases, of course, being considered as hydro-carbon gases), is a mixture of the following:

Nitrogen—introduced mainly with the air used for combustion.

Water Vapor—resulting from the burning of the hydrogen of the hydro-carbon gas with the oxygen of the air to water.

Oxygen—if an excess of air has been used for combustion.

Carbon monoxide—if a deficiency of air has been used for combustion.

Carbon dioxide—resulting from the burning of the carbon of the hydro-carbon gas with the oxygen of the air.

Moisture or water vapor in furnace atmospheres is a very important factor not only insofar as it affects the steel in itself, but insofar as it affects the gas reaction. Perfectly dry gases are quite inactive insofar as reacting with each other is concerned and also insofar as reacting with metals is concerned. Perfectly dry gases are very rare. Jominy[1] has shown that perfectly dry hydrogen, for example, is neutral towards steel up to temperatures as high as 1600° or 1700° F., but that if it contains as little as .1% of water vapor, it becomes a very active decarburizer towards steel even as low as 1200° or 1300° F. Guthrie[2] has shown that perfectly dry raw gas is a very poor carburizer for steel, but that, if a small and controlled percentage of water vapor is introduced, it becomes an active carburizer. Moisture is, therefore, not only of importance insofar as it affects gas reaction leading towards equilibrium condition in the gas atmospheres, but also insofar as it affects the reactions which take place between the gases and steel in the furnace.

Combusted gases which are stable against one another at a given furnace temperature, may easily not be stable towards steel at that temperature and the presence of water vapor will accelerate the steel-gas reaction. If the combusted gases are not stable against one another at the particular temperature at which the furnace is operating, they will react among themselves and in this reaction, which is accelerated by the presence of water vapor, they will develop certain quantities of nascent gases which in turn will be more active towards work in the furnace.

In addition to water vapor acting as a catalyst for many of the reactions between the gases in furnaces, we must also consider that iron itself is apparently a catalyst for many of these reactions and as such causes a greater activity of reaction at the surface of the steel than elsewhere in the furnace. This means that the quantity or concentration of nascent gases at the surface of the steel is greater than elsewhere and, therefore, the effect of such gases upon the steel is accelerated. The steel scales, corrodes, carburizes, decarburizes, nitrides, etc. according to what the gases are and the rate at which they are supplied to the surface of the steel and the rate at which they react at such surfaces.

Neutral Atmospheres:

The question naturally arises as to what really constitutes a neutral atmosphere in steel treating work. General acceptance is that carbon dioxide is oxidizing,

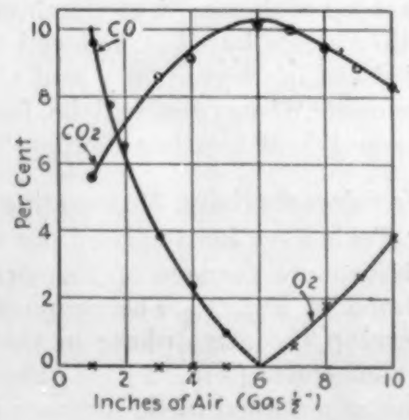

Fig. 3. Typical Atmospheres for various settings of air and gas valve at 2400° F.

oxygen is oxidizing, water vapor is oxidizing, carbon monoxide is reducing, nitrogen is neutral, and hydrogen is reducing. Unburned hydro-carbons, of course, are considered as reducing. If these things are correct, then the amount of reducing gases present should be sufficient to neutralize or balance the oxidizing gases present in order that a neutral atmosphere can be obtained. In the combusted fuel gas types of furnaces, if carbon dioxide is present to any degree, it is generally found that no hydrogen and certainly no hydro-carbons are present, therefore, we need to consider only the balance between carbon monoxide and the carbon dioxide and water vapor or free oxygen. Carbon monoxide and free oxygen both are not present at the same time in a stable combusted fuel gas atmosphere so that we need only balance the amount of carbon monoxide against the carbon dioxide and water vapor.

The above apparently logical assumption, however, with regard to the relationship between various gases in steel is not quite a true picture. It surprisingly has been found that for some steels at temperatures around 1500° F., for example, an apparent neutral atmosphere contains no carbon monoxide at all, but some free oxygen, carbon dioxide and water vapor. If the assumptions that these three are all oxidizing are true, then such an atmosphere would not be considered as neutral. What then is a neutral atmosphere?

The writer proposes that the definition of a neutral atmosphere be freed from any reference to the composition of that atmosphere and be left to mean "an atmosphere which does not react with the material in question at the temperature in question."

An atmosphere neutral towards an oil hardening tool steel need not be, and in fact is not, neutral towards a stainless steel. A consideration of the neutrality of various atmospheres for the heat-treating of steel thus leads us to a consideration of the material being heated in the furnace. Even though the steel comes out of the furnace often apparently free of scale, if it has a soft skin due to decarburization, the atmosphere was not neutral. This was clearly shown by J. J. Curran and G. H. G. Williams.[3]

Decarburization or soft skin is a common occurrence with oil hardening non-shrinking tool steels and with chromium bearing steels especially. It is also common with high speed steel and with aluminum bearing steel such as used for nitriding. It has been claimed by some that soft skin can be eliminated by the use of very high carbon monoxide content in the atmosphere, but there is some doubt as to whether or not their claims have been proven. Soft skin in oil hardening non-shrinking tool steels and carbon tool steels can be eliminated by the use of a combusted fuel gas atmosphere carrying certain percentages of free oxygen. Definite information is still lacking with regard to aluminum bearing steels and many other steels but it is believed that the differences are in matters of degree only and that in these steels certain amounts of oxygen will be found to be required at the normal heat-treating temperatures.

Non-decarburizing Non-scaling Atmospheres:

Tests have been carried out with a combusted fuel gas atmosphere furnace of the certain curtain type as illustrated in Fig. 1. The proportion of gas to air used to develop the atmosphere in the furnace is controlled by manometers (Fig. 2). Curve showing typical atmospheres obtained in the furnace for various settings of the air and gas valve with the furnace operating at 2400° F. are shown in Fig. 3. Plain carbon tool steel was heated to regular quenching temperatures in a furnace of this nature and various furnace atmospheres experimented with. Furnace atmospheres were determined by means of Orsat analyses made upon samples of the gas withdrawn through a nickel tube inserted to about the center of the furnace. Samples were withdrawn only after the furnace had been operating on one setting of the valves long enough so that we were reasonably certain that equilibrium conditions had been arrived at in the body of the furnace. Tests were carried out on carbon tool steel with atmospheres varying all the way from air containing 18-20% of oxygen to a combusted gas atmosphere containing some 12% of carbon monoxide. With the high oxygen concentrations as in air, considerable scaling developed and with high carbon monoxide concentrations soft skin developed. With oxygen content of around 4%, it was found that at a temperature of 1500° F. practically no scale formed and no decarburization resulted on plain carbon tool steel. This was tried out on oil hardening non-shrinking tool steels and similar results obtained. At 1600° F. apparently around 2.5% of oxygen present in the combusted fuel gas atmosphere is indicative of an atmosphere which is fairly neutral to plain carbon steels and chrome-vanadium steels.

At temperatures of 1800° F., the only real work carried out to date has been with stainless steel and indications are that a fairly neutral atmosphere at this temperature for stainless steel is one containing from 8-10% of free oxygen. Work on the pre-heating of high speed steel of the 18-4-1 type at temperatures around 1600° F. indicates that decarburization will result unless from 2-3% of oxygen is maintained in the atmosphere. This percentage of oxygen causes no scaling on high speed steel at this temperature. At temperatures of 2300° F. again with 18-4-1 high speed steel, scaling and decarburization results apparently from the presence of any free oxygen, and from 1-2% of carbon monoxide is required to obtain neutrality. At 2360° F. again with high speed steel of the 18-4-1 type, some 5% of carbon monoxide is required for neutrality, and at 2400°F. fully 10% is necessary. Experimental work has not been carried out on cobalt bearing high speed steels to a sufficient degree to determine what is a proper atmosphere for the same if one can be found. To date results have indicated that this steel is very liable to serious soft skin.

From the above information, it is evident that as temperatures are increased the oxygen present in the atmosphere must be reduced until it has reached zero and then carbon monoxide must be increased until at higher temperatures considerable carbon monoxide is necessary.

In attempting to apply any of the above information to the actual heat-treatment of steel, it must be borne in mind that gas atmospheres not only have their effect upon the surface conditions of steel in the furnace during heat-treatment, but also upon the internal structure of that steel. Sufficient information is not yet available to state just what effect is had on steels of the plain carbon tool steel type or for that matter on any steels at temperatures below 2000° F., but for temperatures above 2000° F. fairly definite information is available that grain growth is seriously affected by furnace atmospheres.

It is hoped that in the future additional work will be possible along these lines and it is also hoped that many others will become interested in this work and will publish their results so that eventually a fuller and more complete picture will be available of the effect of furnace atmospheres not only upon the surface, but upon the structure of steel and other metals.

[3]Decarburization of High Carbon Steel in Reducing Atmospheres. *Transactions American Society for Steel Treating,* Vol. 14, 1928, page 809.

Sintered Tungsten Carbide Brinell Balls

By HAAKON STYRI *

THE BRINELL test is the most universally used method for hardness testing because of its convenience and reliability. When using the ordinary Brinell ball, however, it is not satisfactory for material of greater hardness than about 600 Brinell, on account of the large permanent deformation of the ball at the contact point.

Of the many efforts to increase the hardness of the ball, the best known is the work hardening of the ball, introduced by Hultgren.[1] With this ball it is possible to reproduce results within 1% up to 650 Brinell with certain precautions that will be discussed later. A careful study on iron-carbon-vanadium Brinell balls was published[2] by Quick and Jordan, indicating some improvements on the work hardened Hultgren ball.

Attempts have previously been made to produce tungsten carbide balls in order to use the Brinell method for measuring greater hardness and some foreign made tungsten carbide balls have been obtainable on the market. Recently, satisfactory and accurate tungsten carbide balls have been produced in the United States through the coöperation of the Carboloy Company and the Atlas Ball Company. The rough ball blanks with diameter and sphericity variations of several thousandths of an inch, are furnished by the Carboloy Company, Inc. The Atlas Ball Company has developed a grinding method whereby these extremely hard, rough blanks are ground to within an accuracy for diameter and sphericity of better than 0.000025".

It has been, of course, of particular interest to compare the relationships between Brinell numbers obtained with this new Carboloy ball and Brinell numbers obtained with the Hultgren ball, with the Rockwell diamond cone numbers and the Vickers pyramid numbers obtained on the same materials. For test purposes 8 disks ½" thick of 1% C and 1.5% Cr were cut from the same bar, quenched in brine from 850°C. and tempered at different temperatures as shown in the table. In addition a specimen of tantalum carbide (G77B - Carboloy) was used.

After fine surface grinding and papering of the specimens one impression was made with a 5 mm. Hultgren ball. The diameter was measured and estimated to the nearest 0.01 mm. with a Bausch & Lomb microscope and the permanent deformation of the ball measured with an optimeter and estimated to the nearest 0.00001". All the readings were made by 2 independent observers and did not differ more than these amounts. After the first impression the same spot on the ball was used for 10 more impressions, which all proved to be very much alike and did not increase noticeably for the later readings even for the hardest steel discs. The 11 readings were therefore averaged and the total permanent deformation after the 11th impression was again measured. A new ball was used for each disk.

The Hultgren balls which had been used on disks 4 and 5 were then used with the same contact point on disks 1, 2 and 3 and the Brinell hardness obtained. It will be noticed that these Brinell readings are lower than the previous readings made with balls that had not been used on the hard material. On the other hand the deformation of the ball in the first test on the hard material of disk 4 and 5 is so large that later impressions on the same hard material are not materially affected.

Similar tests were made with 5 mm. Carboloy balls, and in addition also with the Carboloy ball which had been used for 100 impressions on disk 5. All impressions read within 1% difference in diameter. The permanent deformation of the Carboloy ball was 0.009 mm. (0.00036") after 11 impressions on disk 5, and increased to 0.012 mm. (0.00048") after 100 impressions. The Brinell hardness obtained on disks 1, 2 and 3 with this Carboloy ball in the same position shows that there was practically no effect from 100 impressions at 780 Brinell on the observed diameter of impression on the softer disks.

The impressions made with Carboloy balls are much easier to read in the microscope than impressions made with the Hultgren balls, particularly on harder material, as shown in the illustrations of impressions on disk 5.

The Rockwell hardness of the steel disks was measured as an average of 10 impressions and of the tantalum carbide (G77B) as an average of 3 impressions. The Rockwell machine was standardized against a Rockwell C standard sample of 66 to 67 R.C. 150 kg. The value used was 66.4 R.C.

The Hultgren ball failed absolutely on the tantalum carbide, giving a greater diameter of impression than for disk 4 due to flattening, and the impression was difficult to read, while the first impression of the Carboloy ball was easy to read and gave

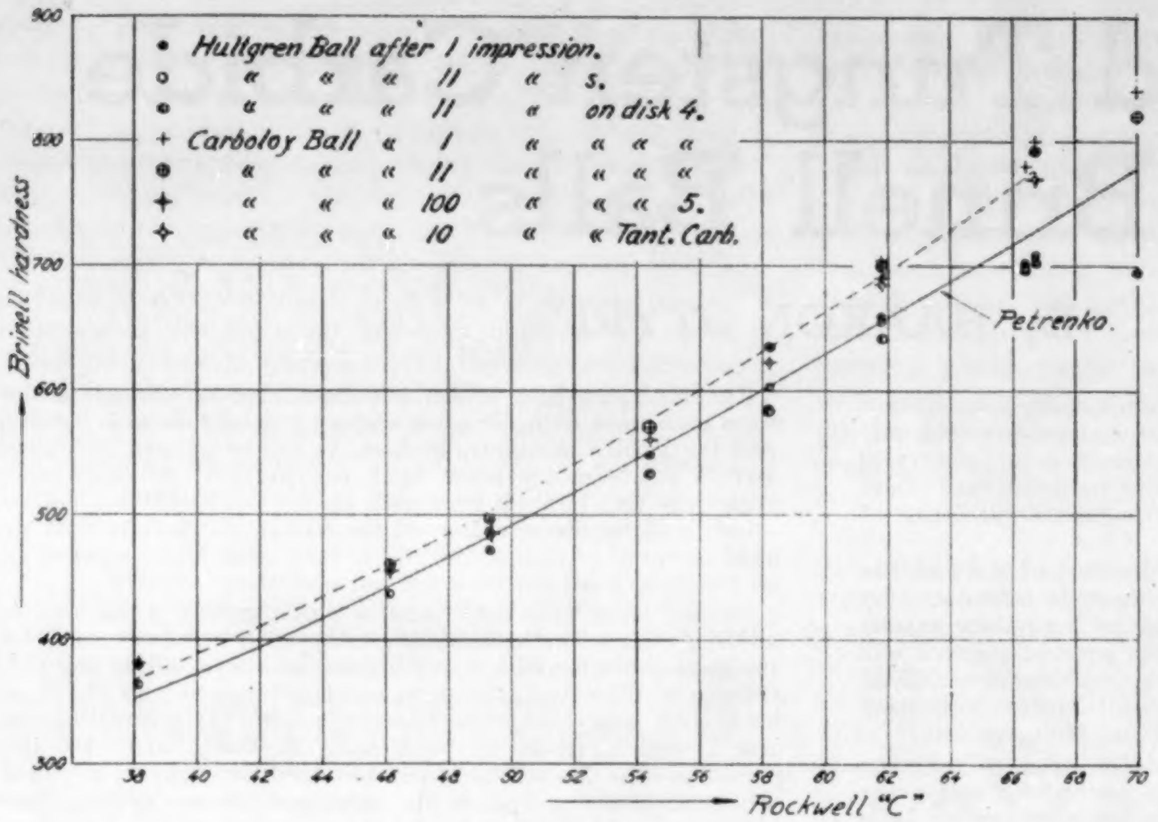

Graph 1

lum carbide sample the obtained Brinell numbers are lower.

Quick and Jordan found the flattening of a 10 mm. iron-carbon-vanadium ball to be about ½ the flattening of a Hultgren ball on hard material, but obtained only slightly higher Brinell number. The 5 mm. Carboloy ball also flattens about ½ of the 5 mm. Hultgren ball on hard material but gives noticeably higher Brinell number, which may be due to a greater modulus of elasticity of the sintered tungsten carbide.

In ordinary practice it is most convenient to use the ball in a fixed position in the holder and a conversion table for Rockwell C to Atlas-Carboloy ball should therefore be based on the values represented by the dotted line in the graph. The Carboloy ball would then give consistent results on material softer than 67 R.C. after a few preliminary impressions on the hard material. The Carboloy ball should not be used for harder material than about 67 on account of the greater deformation. Similarly, a Hultgren ball for general application should not be used for impressions on material over 62 R.C.

840 Brinell hardness. The subsequent 10 readings for the Carboloy ball averaged 820 and the corresponding ball deformations for the readings were respectively 0.009 mm. (0.00036") and 0.014 mm. (0.00056"). After these 10 impressions on the tantalum carbide specimen the Carboloy ball was used in the same position on disks 1, 2, 3, 6, 7 and 8, and the resulting hardness is not much below the values for the ball used 100 times on disk 5.

In order to show the results obtained on this material in comparison with some of the most comprehensive data previously published Petrenko's[3] curve as plotted from his empirical equation derived from experimental values obtained with 10 mm. balls at 3000 kg. for various samples is shown as a solid line in Graph 1 and the values in the table are given as points. Petrenko's individual values fall within ± 10% of his curve, and the average values obtained in the present experiments with new 5 mm. Hultgren balls practically coincide with Petrenko's curve from 46 to 62 R.C. However, if the values are taken with a Hultgren ball that has already been used on hard material, these latter values will be found lower than Petrenko's. This may be due to using both different standards and different Rockwell machines in the tests, and a direct comparison between the 2 tests can not now be made.

The average values obtained with the 5 mm. Carboloy balls are consistently higher than those obtained with 5 mm. Hultgren balls, and the difference increases with greater hardness of the sample but the average points are not more than 10% over Petrenko's curve. The first impression values are generally higher than those made later, but even values obtained on the softer disks after the Carboloy ball has been used 100 times on a hard disk are not much lower than the first. However, after the ball has been used 10 times on the hard tanta-

[3]*Bureau of Standards Journal of Research,* Vol. 5, July 1930, page 19.

The relation between Vickers Pyramid number, 30 kg. load and Brinell readings with these 2 types of balls as well as with Rockwell C 150 kg. is shown in Graph 2. It is quite evident from this graph that the readings obtained with the Carboloy ball come much closer to being proportional to the Vickers P.N. than the Hultgren or Rockwell readings.

A further test of interest was made on the Carboloy ball. After 100 impressions on disk 5 the ball was turned slightly so that the first flattened portion would intersect a new impression. While the impression now became irregular in shape the mean of long and short axis still read about the same hardness as before, namely, 795 for 10 impressions on disk 5.

Carboloy balls have also been used to advantage for hardness testing at temperatures up to 1600°F. and no softening has been experienced.

Through the courtesy of N. L. Mochel, the Vickers Pyramid Numbers of these specimens were made at the metallurgical laboratory of the Westinghouse Electric & Manufacturing Company, Lester Branch.

The assistance of H. O. Walp of the SKF Research Laboratory in making the other tests is gratefully acknowledged.

The Resistance of Copper and Its Alloys to Repeated Stress

By H. W. Gillett*

Part IV. The Bronzes and Special Alloys

IT WAS pointed out in Part III of this review** that the brasses, even in the optimum cold-worked and stress-relieved condition yet obtained, do not give endurance limits as high as 30,000 lbs./in.², and are somewhat adversely affected by combined corrosion and repeated stress. The search for copper alloys of higher endurance must therefore extend into the bronzes and special alloys. The ordinary wrought tin bronzes and phosphor bronzes of Table 1 A give endurance limits of about the same magnitude as the brasses, all running below 30,000 lbs./in.². In Table 1 B there is one "bronze" mentioned by Gough[1] without stating the composition or the number of cycles of the endurance test, which is said to show 40,000 lbs./in.² endurance, but this may be a special bronze and not a tin bronze.

As was the case with copper and the brasses, there is indication (Nos. 3, 4 and 6, Table 1 A) that severe cold work, while it raises the tensile strength of rod stock, lowers the endurance limit, the softer bronzes showing higher endurance. This is not shown by the work of Townsend and Greenall[2] (No. 9-11, Table 1 A) on sheet, but the tendency is shown by the way the endurance ratio drops.

There are no data on cast phosphor bronze. Data on several commercial tempers and on alloys of low tin content, such as 1½% Sn, are lacking. The effect of changes in P for a given Sn content and vice versa have not been systematically covered.

Wrought aluminum bronze, however, with 8 to 12% Al and say 2 to 3% Fe, is, as Table 2 A shows, a material of valuable endurance properties, its endurance ranging from a minimum not much below the maximum for the brasses, up to a maximum of say 35,000 lbs./in.² for rolled, and 42,000 lbs./in.² for extruded material. No data on sheet are available. Cast aluminum bronze, properly heat-treated, appears to have from 25,000 to over 30,000 lbs./in.² endurance limit.

Manganese bronze (really a high strength brass), in spite of its good static properties, only gives about 18,000 lbs./in.² endurance limit. Modified compositions (Nos. 3 and 4, Table 3) used abroad, are reported with higher endurance, but without data on the number of cycles of the endurance test, so that few conclusions can be drawn in regard to them. Such data as exist on cast manganese bronze (Nos. 5, 6, Table 3) indicate that cast material is about as good in endurance as wrought material. An unusual low zinc composition (Nos. 10, 11, Table 3) in heavy castings, shows a very low endurance limit and low static properties as well.

Some of the wrought copper-nickel alloys with 40 to 50% Ni, and hence expensive, give endurance limits (Table 4) of the same order as those for aluminum bronze, and under corrosion fatigue do not appear as attractive as the aluminum bronzes.

Some of the special manganese-silicon-copper and nickel-silicon-zinc-copper alloys (Table 5) which have good static properties are disappointing in their endurance properties. The silicide alloys that are given high tensile strength by a precipitation-hardening heat treatment are prone to have a low endurance ratio so that their endurance limits lie pretty much in the same range as those of the ordinary brasses. On account of their high copper content, they may be good under corrosion-fatigue, but data on this, as well as on notched endurance tests and on cast alloys of this type, are lacking.

However, it is possible for a precipitation-hardened copper alloy to show outstanding endurance properties, for, while accurate data are still lacking, preliminary reports by Siemens and Halske[3] and Stock[4] state that a copper beryllium alloy of about 2½% Be, given a precipitation hardening treatment, has the unusual tensile strength of 192,000 lbs./in.² and stands 16 million cycles when stressed at nearly 100,000 lbs./in.², while in a comparable test, phosphor bronze broke in less than half a million cycles at 57,000 lbs./in.² Frank[5] claims that such an alloy stood 25 million cycles without failure at a stress at which a phosphor bronze spring alloy failed in 0.4 million cycles. He also states that in comparison with a standard spring steel which failed at a certain stress (not stated) in 2 million cycles, the Cu Be alloy had not failed at 3 million.

However, the National Physical Laboratory[6] states that failures of Cu Be spring plate material have been met in testing up to as much as 65 million cycles, and that tests must be carried to a very large number of cycles for accurate determination of the endurance limit.

The stress at which failure occurred at 65 million cycles is not stated. A still later account† of the N.P.L. work, which does not go into detail, indicates that the Cu Be alloy may not be sensitive to the notch effect, since the statement is made that in the case of spring-plate material repeated bend tests have indicated that any deleterious effect of the surface on "as rolled" plates, is small. Work on endurance of the Cu Be alloys is also in progress in this country.

It would seem probable that the Cu Be alloys will be found capable of being given the highest endurance limits of any known copper-base alloy. Their high copper content should give them good corrosion-fatigue properties, though this of course needs experimental verification. The possibility of forming the alloy in the soft state and then hardening it by heat treatment would make it attractive for the sylphon type of bellows and similar articles if it is found suitable for such uses.

Corrosion Fatigue. The data on corrosion fatigue for specimens listed in Tables 1-5 are summarized below:

Table	No.	Tensile	Endurance lbs./in.²	Corrosion Fatigue lbs./in.² Salt Water	Corrosion Fatigue lbs./in.² Carbonate Water

2 A	16	83,500	40,000 (15)	30,000 (50)	30,000 (10)
Cu Ni Alloys					
4	1	85,000	37,000 (100)	25,000±	24,000 (50)
4	2	----	32,000 (60)	25,000±	24,000±
4	3	96,500	41,000 (100)	21,000 (60)	20,000 (70)
4	4	66,500	30,000 (4)	22,000 (20)	21,000 (70)
4	11	98,000	36,000 (100)	....	22,000 (70)
4	12	70,500	26,500 (40)	....	22,000 (70)
4	13	62,500	25,500 (40)	....	20,000 (60)
4	14	47,500	18,000 (100)	18,000 (80)	18,000 (50)

It will be seen that the phosphor-bronzes do not as a rule have their fatigue limit much lowered by simultaneous corrosion in salt or carbonate water. The aluminum bronzes, though in some cases somewhat affected, have, as a class, higher corrosion fatigue limits than do the tin bronzes, and the aluminum bronzes are also, as a class, superior to the more expensive Cu Ni alloys.

The corrosion-fatigue limits as a rule are not much higher on cold-worked than on annealed material, where comparative figures are available. No data are available on corrosion fatigue of manganese bronze or of any of the special alloys of Table 5.

Notches. Ludwik[7] fails to find a lower endurance limit from the presence of notches on bronze of unknown composition (Nos. 7 and 8, Table 1 B), but, as previously pointed out, he fails to find a notch effect on materials which show it, according to data of other workers. The other data summarized below, chiefly on Cu Ni alloys from the work of McAdam[8], indicate that in the notched condition the Cu Ni type alloys come down to the same level, irrespective of how much higher their un-notched endurance limits may be.

Miscellaneous						
Schmidt	9	65 Cu 25 Pb 6 Ni 2 Sn 2 Zn			10,000 (2)	5,700 (2)
Schmidt		85 Cu 9 Sn 4 Ni 2 P			11,500 (2)	9,000 (2)
(No static properties given)						

There is a fairly close approach in most cases to what appears to be the normal relationship, i. e., the torsion endurance limit approximating 50% of that for rotary bending.

Summary. Phosphor bronze is relatively immune to corrosion fatigue in salt or fresh water, but does not have a very high endurance limit to start with. Aluminum bronze is outstanding for endurance limit and for corrosion-fatigue resistance, among commercial materials.

Copper-beryllium alloys, with a precipitation-hardening heat-treatment appear to be, on incomplete data, of outstanding possibilities.

Cast aluminum bronze, properly heat-treated, has almost as good endurance as the wrought material. Almost no data are available on ordinary bronze and red brass castings. Professor Sachs, in Germany, is studying these, but his data are not yet complete.

On account of the relatively low tensile strength of such alloys and the low endurance ratio generally found on wrought alloys of that class, their endurance limits may be expected to be low.

Many commercial compositions and tempers of wrought bronzes and special alloys have not been studied in respect to endurance. In spite of the hundreds of individual endurance tests that have been tabulated in this series of articles, much remains to be done before the endurance properties of copper and its engineering alloys are thoroughly understood.

Because of the inapplicability of short-cut tests, the necessity for running to a very large number of cycles and the variety of the endurance ratio (which makes it impossible to make even a good guess at the endurance limit from the static properties, as can be done with steel), a complete survey would be a tedious task.

However, the variability of the endurance ratio and the facts already on record as to the importance of avoidance of over-cold-working and of stress-release, offer hope for the development of copper-base alloys of decidedly improved endurance properties over those now met in commercial alloys, by means of a systematic study of the alloys aimed to develop better endurance. Similar studies on aluminum alloys are resulting in the production of new alloys that may have only mediocre static properties, but are superior in endurance, for uses where endurance is the most important property. Such improvements in the copper-base alloys also might well result from increased attention to their endurance properties.

Since this correlated abstract was prepared, Gough and Sopwith* have reported on some tests in vacuo. The specimen was enclosed in a sylphon bellows, which was evacuated down to about a millionth of an atmosphere, while the specimen was under repeated axial stress in a Haigh machine. Preliminary tests in a less perfect vacuum had also indicated no effect on a larger series of steels, little on a magnesium alloy with 2½% Al, and wide scatter on duralumin with apparently some improvement due to exclusion of air during the test.

In the tests in a high vacuum a carbon and a Ni Cr steel showed no detectable difference between results in air and in vacuo. An annealed 80:20 cupro nickel (with 0.19% Fe) of 50,000 lbs./in.^{2} tensile, 44% elongation, 68% reduction also gave the same endurance limit, 18,000 lbs./in.^{2}, as in air.

Annealed copper (0.04% oxygen, traces of Pb and As) of 32,500 lbs./in.^{2} tensile, 59% elongation, 74% reduction, gave 10,000 lbs./in.^{2} endurance limit (30 million cycles) in air or lanolin, and is estimated from three tests to 20 million cycles to have an endurance limit in the high vacuum of 11,000 lbs./in.^{2}. The evidence on copper is not very conclusive due to the small number of tests.

But annealed 70:30 brass (with 0.04% Fe, trace Pb) of 44,500 lbs./in.^{2} tensile, 84% elongation, 85% reduction giving 16,000 lbs./in.^{2} endurance limit on a 20 million cycle basis either in air, or when covered with lanolin, rose to 20,500 lbs./in.^{2} in the high vacuum. This reported behavior of brass appears striking, since the S-N curve seems to be quite clearly established, 8 specimens having been used. The stress for a life of 3 million cycles was 22,500 lbs./in.^{2} in vacuo and 16,500 in air. The authors conclude that the improvement in endurance due to prevention of access of air during repeated stress, although clearly indicated only in one of the materials tested, proves that the "air endurance limit" can no longer be regarded as the standard limiting stress.

No sign of the corrosion postulated to explain the lower results on brass in air could be seen on the tested specimens. Further tests are planned to try to find whether the postulated invisible corrosion is to be ascribed to oxygen or to water vapor. The air endurance limit of the brass is stated to agree with that determined on the same material and with the same Haigh machine some five years before. But Gough** tabulates, in his book, for material No. 100, annealed 70:30 brass of the same mark (B1F1) and same analysis and static properties as the brass used in these tests, an endurance limit in rotary bending for 60 million cycles, of 20,000 lbs./in.^{2}. These rotary bending tests are not referred to in the article by Gough and Sopwith.

If the same material shows the same endurance limit in air in rotary bending that it does in vacuo in axial repeated stress tests, but falls down in air on the latter type of test, the situation becomes still more complicated. Since a marked difference between tests in air and in vacuo appeared only in the case of this lot B1F1 of 70:30, it will be well to await further data before drawing very sweeping conclusions.

Readers' Comments, continued from page 269

complete aging and yields maximum hardness. If precipitation has not been complete in the quenching bath, it may continue, with increased hardness, at room temperature or by artificial aging at a temperature slightly higher for a short time until maximum hardness is obtained. This has been observed. Aging at higher temperatures (tempering) results in agglomeration of the precipitated carbide particles resulting in the formation of troostite and of sorbite and in decreased hardness as demanded by the precipitation theory. If the transformation of austenite takes place slowly at some 700°C. submicroscopic particles of the carbide must likewise form (the martensitic stage) before agglomeration giving rise to troostite, sorbite and pearlite can occur. In the transformations we are studying, constituents cannot reach microscopic dimensions without first passing through the submicroscopic stage.

Messrs. Guthrie and Comstock express the belief, shared by others, that on slow cooling austenite transforms directly to pearlite without passing through the troostitic and sorbitic stages. It is an important question and one which should be settled to the satisfaction of all.

The ferrite and the cementite lamellae, of which pearlite is constituted, did not spring full grown from mother austenite. Their birth and growth involve two transformations (1) an allotropic transformation of the solvent, which changes from γ to α iron, and (2) a precipitation of the carbon out of solution as the carbide Fe_3C. Like all crystalline transformations, these changes are gradual. They proceed from zero to completion, passing through submicroscopic and increasing microscopic dimensions; submicroscopic α grains must form within the γ matrix and increase in size and number until the allotropic transformation is completed. Likewise, submicroscopic particles of cementite must form and increase in size and number before the rejection is completed. Stages must necessarily be passed through when the alloy contains both γ and α iron in various proportions, and both crystallized Fe_3C and carbon in solution before reaching pearlitic equilibrium. The very nature of the transformations demands it. Those stages correspond to the so-called transition constituents, troostite and sorbite. It follows from the above considerations that no exact composition can be ascribed to these constituents. They represent various phases in the agglomeration of the carbide particles and in the extent of the allotropic transformation. Will not some one indicate the fallacy of this reasoning and explain how full grown lamellae of α ferrite and of cementite may form from a solid solution of carbon in γ iron without being at their birth of submicroscopic size, without their gradual increase to microscopic dimension, without passing through aggregates of γ and α iron, of crystallized Fe_3C and carbon in solution?

The microstructure obtained by Messrs. Guthrie and Comstock in which they find martensite and pearlite in close juxtaposition appears to me to have little significance in view of the manner in which the experiment was conducted. In order to trap in the quenching bath the austenite in process of transformation and, therefore, exhibiting the transition constituents troostite and sorbite, it is necessary to have a thermal gradient extending from the austenitic range into the pearlitic range. In their experiment, this heat gradient was so narrow as to be practically non-existent. Consider that the lead bath was kept at a temperature of only 1300°F. while the critical transformation is given as 1290°F. a gradient of 10°F. Had they kept their lead bath at a higher temperature, 1500°F. for instance, I believe that they would have found troostite associated with martensite. Similar experiments have been frequently performed.

Percent Elongation in the Tensile Test as a Method of Measuring the Ductility of Thin Sheets

To the Editor of Metals & Alloys:

I have just received the October copy of Metals & Alloys and note with considerable interest, the article by Mr. Reid L. Kenyon, "Percent Elongation in the Tensile Test as a Method of Measuring the Ductility of Thin Sheets." In the second column of this article on page 220, under the general heading, "Outline of Tests," Mr. Kenyon makes the statement in the first sentence . . . "but in these tests there was no variation in length of parallel section for a given gage length." This is not in agreement with the facts as can be seen by reference to the paper referred to. Opposite page 380 of the A.S.T.M. Proceedings Vol. 26, 1926, Part II, will be found the detailed dimensions of the whole series of specimens where the parallel section was varied, as well as, the width of the specimen, while the gage length was maintained at 2 in. throughout. The data from these tests will be found on pages 382 and 383 and 384. The results have been plotted in Fig. 6, page 386, to show the relations between elongation and length of reduced section.

It is indeed a pleasure to see that Mr. Kenyon's results give the same answer that I obtained in the earlier tests, to wit: that the length of reduced section does not appreciably affect the elongation results as long as the parallel section is slightly longer than the gage length used.

R. L. Templin,

Chief Engineer of Tests
Aluminum Research Laboratories

New Kensington, Pa.

CURRENT

METALLURGICAL ABSTRACTS

A digest of the important metallurgical developments of the world

METALLURGICAL ABSTRACTS, incorporated in METALS & ALLOYS, is the most complete review of metallurgical literature (periodicals, books, etc.) available. Fifty section editors and abstractors cover over 500 domestic and foreign publications and abstract the articles on metallurgical engineering as well as allied subjects.

Upon receipt of the abstracts they are checked against permanent files to avoid duplication and after being rewritten to conform with our style they are classified. The section editors edit the abstracts appearing in the section in which their major interest lies.

There are usually at least two places where an abstract might fit, sometimes even more, and so we decide who will be most interested in the article. We want the abstracts to be so arranged that if a heat treater reads only Section 10 he will keep in touch with all the important articles in his field and if a foundryman will read Section 22 each month he will not miss anything important. An improvement we hope to make in the METALLURGICAL ABSTRACTS in the near future is the cross-indexing of articles which belong under several sections. Some of the sections are descriptive and some are self-explanatory and we have so labeled them.

CLASSIFICATIONS

0 (General). Under this heading we classify all abstracts which are of interest to the metallurgical industry in general.

1, 2, 3 (Properties of Metals, Non-Ferrous and Ferrous Alloys). An article goes under one of these heads when the properties are emphasized and not the method of determining them.

4 (Corrosion, Erosion, Oxidation, Passivity & Protection of Metals & Alloys). This takes articles on weather resistance, resistance to acids, etc. and protection against them.

5a (Structure of Metals & Alloys—Metallography & Macrography) An article would go in this group if it discussed the microscopic or macroscopic study of metals and alloys, or the determination of constitutional diagrams, critical points, etc.

5b (Structure of Metals & Alloys—Structure and X-Ray Analysis). This group includes articles dealing with the structure of metals and alloys as determined by X-ray analysis and X-ray examination.

6 (Physical, Mechanical & Magnetic Testing). If an article emphasizes the method of determining the properties of metals rather than the properties themselves it belongs in this section. The abstracts on fatigue appearing under this section are prepared with the coöperation of the Fatigue Research Committee of the American Society for Testing Materials.

7a (Electro-Chemistry—Electroplating). This will include articles on the electrolytic plating of metals.

7b (Electro-Chemistry—Electrometallurgy). This relates to the electrolytic recovery and refining of metals.

8 (Metallic Coatings Other than Electroplating). Articles on galvanizing, metal spraying or dip coating would come in this group.

9 (Industrial Uses and Applications). If the application of the metal is stressed rather than the properties the article belongs in this section.

10 (Heat Treatment). If heat treatment in general is discussed the article would be classed under section 10; if, however, any distinct operation is stressed it would go under the corresponding subhead.

11 (Joining of Metals and Alloys). The explanation for this group is similar to that for section 10.

12 (Working of Metals & Alloys.) We feel that the divisions in this group are self-explanatory to men in the metals industries. We might say, though, that an article is classified under 12j (Cold Working) only when it will not fit under one of the other heads—for instance, an article on cold rolling would be put under 12c, rolling.

13 (Defects). This section includes articles dealing with inclusions, segregations, cracks, pinholes, blowholes and failures.

14 (Chemical Analysis). If the method of analysis is emphasized the article goes here.

15 (Historical & Biographical). Self-explanatory.

16 (Economic). Articles in this group are devoted to economic trends, savings, cost estimates, etc.

17 (Plants & Laboratories). This section includes descriptive articles.

18 (Machinery & Supplies). This includes descriptive articles.

19 (Bibliographies). Self-explanatory.

20 (Miscellaneous). This takes in all scattered articles which do not belong anywhere else.

21 (Laboratory Apparatus). Purely descriptive articles belong here. If results or processes are given they would go under 6 or 14.

22 (Foundry Practice & Appliances). This is self-explanatory.

23 (Furnaces & Fuels). This takes in descriptive articles. Otherwise they go under 10, heat treating, 10b, annealing, etc.

24 (Refractories & Furnace Materials). This section is hand-in-hand with 23. Furnace men should read both of them.

25 (Gases in Metals). This is self-explanatory.

26 (Inspection). This includes articles dealing with inspection, pure and simple—not X-ray or microscopic analysis.

27 (Effects of Elements on Metals and Alloys). Articles dealing with the effect of the addition of different chemical elements to metals and alloys are included in this group.

28 (Instruments & Controllers). Descriptive.

29 (Effect of Temperature on Metals and Alloys). This section is prepared in conjunction with the Joint High Temperature Committee of the A. S. T. M. and the A. S. M. E.

30 (Leaching). Self-explanatory.

31 (Reduction Metallurgy). This would include articles on blast furnace practice.

32 (Non-metallic Coatings for Metals and Alloys). Articles discussing painting, enameling, lacquering, etc., belong here.

◆ ◆ ◆ ◆ ◆

It has been our purpose in this outline to make our scheme of classification apparent to our readers and so, perhaps, make the abstract section more useful. If you have any questions pertaining in any way to the abstracts, write to us. We shall be glad to answer them in detail.

The classification number at the end of each abstract will be of assistance in mounting them on file cards.

Negative print photostats of the original articles abstracted below can be obtained at 35 cents per page, plus 10 cents for mailing first class. The remittance should accompany the order.

(See back cover)

GENERAL (0)

Alloy Steels. Robert Hunter. *Transactions Institution Engineers and Shipbuilders in Scotland*, Vol. 72, Yearbook 1929, pages 696–703.
A discussion of alloys now available. WHB(0)

The Story of Steel. J. Henderson. *South African Mining & Engineering Journal*, Vol. 42, Part 1, Apr. 4, 1931, pages 141–142; May 2, 1931, pages 245–246; May 9, 1931, pages 263–264.
General. AHE(0)

Structural Steel Research. Fred Grove-Palmer. *Iron & Steel Industry & British Foundryman*, Vol. 4, June 1931, pages 299–301.
Describes program for research. CHL(0)

21st Report of the German Atomic Weight Commission. (XI. Bericht der Deutschen Atomgewichts-Kommission.) M. Bodenstein, O. Hahn, O. Hönigschmid & R. J. Meyer. *Berichte der Deutschen Chemischen Gesellschaft*, Vol. 64, Jan. 7, 1931, pages 1–21.
Contains 43 references. The 1931 table of atomic weights is presented and atomic weight determinations made by chemical means during the past year of Ca, Tl, As, Ta, S, Cr, Cl and Re are described. The status of isotope studies is discussed and mass spectroscopic results are given for Kr, Xe, Hg, Cr, Mo, O, N, Cl and Pb. The question of finding stable elements between U and Pb is discussed. A table of isotopes is given. CEM(0)

The Education of a Metallurgist. Harold Carpenter. *Journal Institute of Metals*, Vol. 47, Mar. 1931, pages 3–9.
Review of the aims and systems for training a metallurgist in different countries. The author stresses the point that the college course should, pre-eminently, teach scientific methods because he sees in this the basis of the cultural and intellectual activity of the modern world. Ha(0)

Value of Specifications in the Manufacture of Steel. J. Brunner (Illinois Steel Company). *Preprint, Symposium on Economic Significance of Specifications for Materials, American Society for Testing Materials*, **1931, pages 7–10.**
General discussion of principles governing framing of specifications for steel, their advantages and limitations. HWG(0)

The Effect of the Development of Non-Ferrous Alloys on Iron and Steel. Maria L. V. Gaylor. *Journal Institute of Metals*, Vol. 47, Aug. 1931, pages 1–5.
The very close relationship existing between ferrous and non-ferrous alloys with regard to their development through scientific method is noted; the same fundamental problems are present in both cases; the difference is only in degree. The researches carried out on non-ferrous alloys made from as pure a material as possible have led to investigations with pure Fe and its alloys. The development of the high-frequency induction furnace has especially contributed to the production of pure metals by the possibility of melting in a vacuum. Ha(0)

Specifications from the Standpoint of a Large Purchaser of Engineering and Special Materials. J. W. Bancker (Western Electric Company). *Preprint, Symposium on Economic Significance of Specifications for Materials, American Society for Testing Materials*, 1931, pages 35–43.
Cites value of control of purchases by specification. The tool steel industry furnishes the worst example of the degree of confusion and duplication which a multitude of trade names can cause. However, until recently it was impossible to differentiate good and bad tool steels by routine inspection methods so that the standardization is difficult. No suitable inspection tests are known for welding rod. The domestic screw machine steel industry was given impetus by its effort to meet specifications imposed. Some other metallic products are mentioned in the paper. HWG(0)

In Behalf of a Standard Non-Ferrous Classification. Geo. S. Brady. *Product Engineering*, Vol. 2, Oct. 1931, pages 433–436.
There is a real need for a classification of non-ferrous alloys in a manner in which the engineer, foundryman, mechanic and purchasing agent may be enabled to compare qualities which are expected in alloys. The great number of mixtures with names which are often meaningless render such a basis of comparison impossible at present. While the S.A.E. and the A.S.-T.M. have established certain standards, they are not generally accepted or even widely known. Class names for each group of alloys are suggested, as well as a standard system to designate the contents or grade of the alloy. Standardization should allow a reasonable number of commercial alloys in each of the great groups: the alloys of Al, Cu-Ni alloys, Pb and Sn white alloys and the brasses and bronzes. Ha(0)

Progress in the Properties and Treatment of Metallic Alloys. (Quelques progrès importants dans les propriétés et les traitements des alliages métalliques.) L. Guillet. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 507–523.
Résumé of progress in the last half-dozen years. Steels containing high Cu, or Cu and Cr, steels for resistance to creep at high temperatures, (especially one of 0.30% C, 2.78% Ni, 0.75% Cr, 0.33% Mo), cast Ni-Cr steel, high speed steel with 5% Co and 0.75% Mo beside the usual constituents, use of Ni, Cr and Mo in cast iron, of heat-treated cast iron, of aluminum brasses, nickel brasses, Monel metal, strong Al alloys, Alclad, beryllium steel and of nitrided steels, are cited as important advances. HWG(0)

Text Book on General Mechanical Technology of the Metals. (Lehrbuch der allgemeinen mechanischen Technologie der Metalle.) 6th Edition. Hermann Meyer. Max Jänecke, Leipzig, 1931. Paper, $5^1/_2 \times 8^1/_2$ inches, 332 pages. Price 7.20 RM.
The methods of melting and working the alloys used in machine construction are described briefly but clearly, with the aid of many well-chosen illustrations. The book differs from many textbooks of wide scope in that it is quite up to date. Conveyor systems for continuous molding and pouring in the foundry, the Brackelsberg furnace and nitriding receive mention, for example.
While the space allotted to any one subject prevents going into great detail so that the expert in one field will not find details new to him, yet the avoidance of too great detail gives a better broad picture to the student. Casting, forging, rolling, drawing, stamping, spinning, welding, soldering and heat-treatment are discussed.
Heat-treatment receives rather too little space for correct balance, but in general, the processes are adequately dealt with, for a book of this type.
While the subject is "mechanical metallurgy," physical metallurgy is dealt with as a necessary side issue. While such references are not extensive, they are good as far as they go. The micrographs are of a high order of excellence, as are the paper and printing. There is an index.
This is a good textbook.—H. W. Gillett(0)-**B-**

World Development in Electro Metallurgy. (Le dévelopment mondial de l'électrosidérugia.) R. Sevin. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 247–255.
Brief general discussion of status of electric steel melting in various countries with still briefer comment on electric heat-treatment. HWG(0)

PROPERTIES OF METALS (1)

Magnesium and Beryllium. William Crawford Hirsch. *Electrical Manufacturing*, Vol. 8, Aug. 1931, pages 24–25.
Mg, one third lighter than Al, has been produced commercially for the last 15 years. It has enjoyed a progressive price decline. The pure metal is used chiefly as a deoxidizer and for alloys, also used to degasify radio and other vacuum tubes. Mg ribbon is used to form magnesium oxide coatings on electrical resistor elements. Mg base alloys offer much where light weight and electrical efficiency must be supplemented by mechanical strength. It is available as ingot, rod, tubing, sheet, extruded forms, wire ribbon and powder. Be is also a light metal, but so far is only in its development stages, 98% pure metal now being quoted at $145.00 a pound. Experiment shows that it has definitely assured a place in the roster of electrical materials of the near future. Beryl, the ore, is colorless and clear like glass. Be promises to be valuable as an ingredient in ferrous as well as Cu alloys. When added to Cu in minute quantities Be improves its mechanical properties without affecting the conductivity. It gives a Cu alloy a golden color. Be occurs in more than a dozen different minerals. WAT(1)

Revision of the Atomic Weight of Thallium. Analysis of Thallo-Bromide. (Revision des Atomgewichts von Thallium; Analyse des Thallobromides.) O. Hoenigschmid & H. Striebel. *Zeitschrift für anorganische und allgemeine chemie*, Vol. 194, No. 2/3, 1930, pages 293–298.
The atomic weight of Tl was found, in agreement with a previous determination of Hoenigschmid, to be 204.390 ± 0.008. Ha(1)

Electric and Magnetic Properties of Metals. (Elektrische und magnetische Eigenschaften der Metalle.) R. Becker. *Zeitschrift für Elektrochemie*, Vol. 37, Aug.-Sept. 1931, pages 403–414.
The name "metal" designates a certain definite group of substances which are, however, characterized by properties which differ in accordance with the purpose for which they are used. For instance, the chemist, the electrical engineer and the mechanical engineer each define them according to their specific needs. The author tries to find a generally acceptable definition from the view point of the physicist; he also tries to make it possible to derive from this definition all the properties utilized by the others. Although the electron theory supplies a very satisfactory explanation of the substance of a metal, it has not so far been possible to explain some essential characteristics of a metal; for instance, its technological properties. The author particularly discusses the explanation of electrical and magnetic properties by the authors, Drude, Richardson, Bohr, P. Weiss, the final elucidation by Sommerfeld by applying the Pauli rule and the Fermi statistics. The theory of the free atoms and their distributions and the spin of the electron are explained. By this, a certain momentum is attributed to each atom besides its charge and mass and is responsible for the magnetic properties. A list of references supplements the paper. In an appendix, it is shown how the entropy of a system can be calculated from the formulas representing the Fermi distribution of the free atoms in a metal at the absolute zero point of temperature. Ha(1)

The Present State of Our Knowledge of Super-Conductors. (L'état actuel de nos connaissances sur les supraconducteurs.) A. Boutaric. *Revue générale d'Électricité*, Vol. 28, Aug. 2, 1930, pages 165–172.
The author reviews the work done since Kamerlingh-Onnes discovered, in 1911, that the electrical resistance of metals approaches zero at zero (absolute) temperature. He discusses the different theories which explain this phenomenon. The super-conductivity has, so far, been found only for the following metals; the temperature given is that at which the transition from ordinary to super-conductivity occurs (in ° Kelvin):

Lead	7.2° K.	Tin	3.2° K.
Mercury	4.2° K.	Thallium	2.47° K.
Indium	3.4° K.	Gallium	1.07° K.

The crystalline condition and elastic deformation have considerable influence on the super-conductivity. The table of Kapitza is given for a number of metals. The theory of Riecke and Drude is accepted, to-day, as the most probable explanation of the phenomenon. 16 references. Ha(1)

Handbook of Inorganic Chemistry. Vol. 4. Section 3, Part 2A, No. 1. **Iron and Its Compounds. (Handbuch der anorganischen Chemie.** Vierter Band, dritte Abteilung, zweiter Teil, A, Lieferung 1. **Eisen und seine Verbindung.)** Abegg, Auerbach & Koppel. Verlag S. Hirzel, Leipzig, 1931. Paper, 7 × 10 inches, 336 pages. Price 40 RM.
The topics covered are, atomic weight, J. Meyer; the iron atom, E. Rabinowitsch; preparation of pure iron and its physical properties, K. Fishbeck; pyrophoric and colloidal iron, D. Deutsch; electromotive and electrochemical behavior, H. Danneel. The next volume is to deal with passivity, corrosion, compounds with metalloids and alloys with metals, and the history and occurrence of iron. Though this volume is in a chemical series, it deals almost wholly with the physical properties of iron, of which the magnetic properties are most fully described, 380 literature references being cited.
There being no truly pure iron, only those physical constants are really established which are not materially affected by the impurities of so-called pure iron. In other cases, a process of extrapolation may give a fair approximation, but in a great number all that can be done is to cite the composition of the material studied, insofar as it was determined, and the data obtained on the various samples for the constant in question. The tabulated or plotted data of various workers often show huge variations. The density of a given sample of α-iron at room temperature can be determined precisely to several places of decimals, but that of pure iron cannot be precisely stated to more than one place, i. e., 7.9. The Brinell hardness of pure annealed iron is not known, as figures for so-called pure iron run from 50 to 80. Data for specific heat of molten iron at 1600° C. vary from 0.15 to 0.23. The heat of transformation of β- to γ-iron is given from 2.9 to 6.7. The heat of fusion may be anything from 50 to 70, according to the data one cares to accept.
This state of affairs makes it necessary for all determinations to be accompanied by a statement of the analysis of the material. While it is not very clearly brought out in this volume of Abegg, even that does not fully define the material since the oxygen content of most so-called pure iron samples used in the various investigations has not been determined, and it varies greatly, often being much larger in amount than that of some of the impurities that are determined. The subject thus resolves itself into a discussion of the effect of impurities, particularly carbon, on the various constants, and this is quite well covered.
The editor and his collaborators have painstakingly collected the available data, citing the analysis of the material studied insofar as it is known and have excluded some obviously erroneous data. With all the exercise of their critical faculties, they are seldom able to fix a reliable figure for a constant, without uncertainties of a rather large order of magnitude.
The volume is of great value, not only in presenting data, but in showing their discordance, and the pressing need for the preparation of truly pure iron on a scale sufficient to afford material for the obtaining of data of greater reliability.
That so important a metal as iron is such a stranger in pure form is a challenge to metallurgy that should not go unheeded. The book makes this challenge clear.
While there is a table of contents, there is no index, which seems inexcusable in a reference book of this type.—HWG(1)-**B-**

PROPERTIES OF NON-FERROUS ALLOYS (2)

A Few Mechanical-Technical Properties of the Red Brass Alloys Rg 10. (Zur Kenntnis einiger mechanisch-technischer Eigenschaften der Rotgusslegierungen Rg 10.) WILLI CLAUS. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Apr. 3, 1931, pages 283–285.

Analysis and test results are given and the influence of impurities determined. The tensile strength of this alloy is 20 kg./mm.^{2}, elongation 10%, Brinell hardness 65 kg./mm.^{2}, and bending number 15. Other tables give the properties of this brass if alloyed with Pb and Sb. Ha(2)

Casting Studies on Light Aluminum Alloys. Influence of the Chemical Composition. (Étude de la coulée des alliages légers d'aluminium. Influences de la composition chimique.) ANDRÉ COURTY. *Comptes Rendus*, Vol. 191, Dec. 8, 1930, pages 1128–1130.

Al-Si, Al-Cu and Al-Zn alloys of varying composition were examined by a method described previously. The following conclusions were arrived at: In determining the casting qualities, it is necessary to consider the density of the metal as well as its composition. In the light Al alloys investigated, the "castability" diminishes, within the proximity of the range of pure metal, with an increase of metals in solid solution. In the Al-Si alloys, in spite of the rapid elevation of the fusion point and the distinct decrease in the density, the "castability" was found to be superior in the high-Si alloys (up to 21.72% Si) as compared with the eutectic (13% Si). In the Al-Cu alloys, the alloy of 6% Cu has the "castability" of Al and the alloy of 12% Cu surpasses the "castability" of pure Al by 20%. Within the large zone of the solid solution diagram of the Al-Zn alloys, the "castability" is diminished with an increase in Zn in spite of the rapid increase of the density. It requires 30% Zn to obtain an alloy of the "castability" of pure Al. (2)

Iron-Brasses and Magnesium Brasses. (Les laitons au fer et les laitons au magnésium). L. GUILLET. *Cuivre et Laiton*, Vol. 4, July 15, 1931, pages 303–304.

Brief report of tests shows that the addition of Fe to brass, even up to 1.6% does not produce any important new property. The addition of Mg of less than 0.3% is of no importance but, in larger amounts, it exerts an extremely harmful influence on the mechanical properties. Ha(2)

Precious Metal Alloys. R. C. BRUMFIELD (Cooper Union). *American Society for Steel Treating, Preprint* No. 28, 1931, 22 pages; *Mining Journal*, Vol. 175, Oct. 31, 1931, page 820; Nov. 7, 1931, pages 835–836; Nov. 14, 1931, pages 852–853.

Paper read and discussed before the Boston Convention of the Society in Sept., 1931. The author describes the properties of certain noble metal alloys used mostly for dental purposes. The heat treatment possibilities of increasing the hardness, the workability, the melting points and casting properties are discussed. 22 references. WLC(2)

The Complex Brasses. (Les laitons complexes.) LÉON GUILLET. *Cuivre et Laiton*, Vol. 4, Sept. 15, 1931, pages 399–400.

When adding a metal to another metal, it should go into solution completely; if it keeps its character, it may form injurious constituents. The author shows the manner in which the valency can be used to learn the proportions in which additions should be made to brasses to be sure to obtain real solutions of definite uniform properties. Production and Application of Light Metals and Alloys in Italy. (Production et application des métaux légers et de leurs alliages en Italie.) A. W. BONARETTI. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 903–911.

A general survey. See *Metals & Alloys* Vol. 2, Nov. 1931, page 275. HWG(2)

Non-Ferrous Alloys. L. E. ABBOTT. *Bell Laboratories Record*, Vol. 10, Sept. 1931, pages 13–16.

A general discussion on the importance of non-ferrous alloys, their characteristics and testing, and work done in the Bell Laboratories. Ha(2)

Beryllium and Beryllium Bronzes. (Le glucinium et les bronzes au glucinium.) JOH. BECKER. *Revue Fonderie Moderne*, Vol. 25, Sept. 25, 1931, pages 343–344.

Brief survey of the recently developed Be alloys and their qualities. Pure Be has a density of 1.85, a melting point of 1285° C., is hard to work and costs about 18 francs/g. Technical Be is about 98% pure with about 1% Fe and the remainder of other impurities; price about 5.40 francs/g. Alloys of 80% Be with 20% Fe or Ni are made electrolytically. The beryllium bronzes are refinable by heat treatment; their electric conductivity is twice that of aluminum bronzes or phosphor bronzes. They possess an extraordinary elasticity and are, therefore, used for springs which are under permanent fatigue stresses. Bronzes with 1–2% Be are also very useful for pieces subject to great wear. The study of beryllium alloys has only begun. Ha(2)

Thermal Conductivity, Electrical Conductivity and Lorenz's Coefficient of Some Light-Metal Alloys. (Wärmeleitvermögen, elektrisches Leitvermögen und Lorenzsche Zahl einiger Leichtmetall-Legierungen.) W. MANNCHEN. *Zeitschrift für Metallkunde*, Vol. 23, July 1931, pages 193–196.

The present investigation on thermal and electric conductivity and of the Lorenz coefficient determined on Al and Mg-alloys cover the temperature range from −190° to +200° C. The thermal conductivity λ of light metals is materially cut down by the addition of other elements which effect proved to be more pronounced at low temperatures than at elevated ones. Therefore, the temperature coefficient always yielded a positive value in case of light metal alloys in contrast with pure light metals. Heat-treatment resulted in appreciable changes but further experiments are urged to confirm the present deviations. Similar to the data gained on thermal conductivity measurements were the results from the electrical conductivity (H) determinations. By alloying Si and Mn to Mg, values on electrical conductivity were obtained which are evidently not in agreement with conclusions drawn from the constitutional diagrams. The Lorenz coefficient $\frac{\lambda}{H\,T}$ has been computed and is larger in case of alloys than in case of pure metals. However, attention is called to some deviating results gained on Cu-Al, Mn-Mg and other alloys. EF(2)

The Mechanical Properties of Ultra Light Alloys. (Die statischen Eigenschaften der Ultra-Leichtlegierungen.) N. PARRAVANO & G. GUZZONI. *Metallwirtschaft*, Vol. 20, May 22, 1931, pages 410–414.

Contains 14 references. The practical importance of the elastic limit and yield point rather than ultimate tensile strength of metals is pointed out. See "Static Properties of Ultra Light Alloys," *Metals & Alloys*, Vol. 1, Aug. 1930, page 689. CEM(2)

Recent Research on 18-Carat Gold. ERNEST A. SMITH. *Metal Industry*, London, Vol. 39, Aug. 7, 1931, pages 123–125; Aug. 21, 1931, pages 183–184.

Six references. Color, melting points, solidification ranges, tensile and hardness values and results of Erichsen tests are listed for alloys containing 75% Au, the remainder being Ag and Cu. Mention is also made of the effect of annealing temperature and time and influence of furnace atmosphere especially on Cu rich alloys. PRK(2)

The Noble Metal Alloys and Amalgams in Dentistry. (Edelmetallegierungen und Amalgame in der Zahnheilkunde.) LUDWIG STERNER-RAINER. Hermann Meusser, Berlin, 1930. Cloth, 6 x 9 inches, 111 pages. Price 10 RM.

This book is written largely from the standpoint of the investigator or testing engineer. The work on the noble metals appears to be based mostly upon the author's own researches.

Pages 1 to 27 are devoted to general discussions of the properties of metals, including crystal structure, physical properties and alloy systems.

Pages 28 to 69 are devoted to the properties of gold, silver, copper, platinum, radium, palladium and their alloys. The ternary systems, gold-silver-copper, are discussed with reference to the melting point, toughness, tensile strength, and hardness. Gold alloys of different karats are discussed, composition and physical properties being given in tables. Tables of 92 gold alloys are given with chemical composition, physical properties, liquidus and solidus points. More attention has been given to the physical properties of these alloys than is usually found in a publication of this type.

There is considerable attention given to the effect of heat treatment on the physical properties of the alloys, and some information is given with reference to the various uses of the alloys in the dental profession.

There is a lack of microphotographs, although some of the structures are illustrated by drawings, probably produced by the aid of such equipment as the camera lucida.

Gold solders are included in this discussion of the noble metal alloys.

Pages 70 to 111 are devoted to the discussion of amalgams. In this section of the book the author seems to have depended to a larger extent upon information in the literature. The first few pages are rather historical in character. In the latter part of the section on amalgams, the author has again given a considerable amount of the results of his own investigation. Such subjects as volume changes, crushing strength, hardness, effect of mercury—alloy ratio, and corrosion are discussed with diagrams and tables.

American investigations on amalgams have not been included.

American students in this field will find some additional data in this book and will find some references to European researches, more particularly German investigations.—O. E. Harder (2)-B-

Technology and Use of Electron Metal. (Technologie und Anwendung des Elektronmetalls.) WALTHER SCHMIDT. *Elektrochemische Zeitschrift*, Vol. 37, Aug.-Sept. 1931, pages 508–517.

A tabulation of cast and extruded Mg alloys with Al, Zn, Mn and Si containing at least 90% Mg. Technological properties are given with their possible fields of application. The production and refining, corrosion and danger of burning, machining by different processes and possible savings in weight are discussed. Illustrations show a few examples of designs with electron metal. Ha(2)

Magnesium, Magnesium-Rich Alloys and Beryllium Alloys. T. HENRY TURNER. *Metal Industry*, London, Vol. 36, Jan. 17, 1930, pages 85–89.

Summarizes present uses of these alloys. Mg alloy castings are produced at about same price as Al castings. Percentage of scrap and rejected castings speak in favor of Mg alloys. Elektron is especially suitable for pressure die casting. Heat treating tests on Mg alloys to date give promise of improvement. Alloy castings may be machined with very heavy cuts, without distortion of metal. Considerable progress has been made in production of Mg sheets since the technique of hot working is better understood. Mg alloys require protection from certain corrosive atmospheres and liquids encountered in service. Promising developments have been made in the production of Be alloys of Cu and Ni to be used as temper alloys. These alloys are very hard and strong. Gives various uses. VSP(2)

Discontinuities at the Melting Point of Bismuth. W. L. Webster. *Proceedings Royal Society*, Vol. 133, Sept. 1931, pages 162–172.

The investigations described were undertaken to determine whether Bi, in solidifying, passed through a transitional cubic phase (a suggestion put forward by Professor Kapitza to explain the formation of cracks during the growth of Bi crystals). The experiments show that the temperature of emission of the latent heat of fusion, of the acquisition of rigidity, and of the anomalous diamagnetic discontinuity coincide within an experimental error of 0.3° C. This coincidence leaves no room for such a cubic phase, and another process, based on the self-purification of growing crystals, is suggested to account for these cracks. WAT(2)

Heat Treatment Is Indispensable for Aluminum and Its Light Alloys. (Les traitements thermiques sont indispensables a l'aluminium et aux alliages légers d'aluminium.) M. J. SUHR. *Congrès International des Mines de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 593–598.

The conductivity of Al wire depends on the time and temperature of annealing given. If behavior in the Stanton repeated impact test is a criterion of quality, proper heat-treatment may increase the quality of an Al casting alloy 50 fold or more. The heat-treatments given the different alloys are none too clearly described. See also *Metals & Alloys*, Vol. 2, May 1931, page 95. HWG (2)

The Effects of Cold-Rolling and of Heat-Treatment on Some Lead Alloys. H. WATERHOUSE & R. WILLOWS (Research Department, Woolwich). *Institute of Metals, Advance Copy* No. 584, Sept. 1931, 23 pages.

The effects of cold rolling, heat treatment and aging on the Brinell hardness of 14 Pb alloys were studied. The alloys contained small amounts (3% or less) of Cd, Sn or Sb; some contained both Sn and Cd and others contained both Sb and Cd. Cold rolling hardened the softer alloys and softened the harder alloys but, after aging at room temperature, the hardness of all of the alloys fell to 7 Brinell. Most of the alloys could be age-hardened. In certain of the alloys, the age hardening persisted for at least several months but was destroyed by further work. Certain of the alloys in the age-hardened condition were as strong as the alloy used for battery grid plates containing 5–12% Sb. Contains 15 references. JLG(2)

Metallurgical Problems in Aluminum and Aluminum Alloys. (Metallkundliche probleme bei Aluminium und Aluminiumlegierungen.) G. SACHS. *Elektrochemische Zeitschrift*, Vol. 37, Aug.-Sept. 1931, pages 436–447.

Problems in metallurgy deal, in general, with the changes of properties. 2 groups of causes for these changes are distinguished: The forming of alloys and the mechanical and thermal treatment. In this paper, the author emphasizes the properties of strength and cohesion of Al because these are the most important for the practical application of the metals. First, the results of physico-mechanical tests are described, as well as the production and properties of single aluminum crystals. For the chemical behavior of a material, its position in the vertical column of the periodic system is determining. The mechanical properties, however, seem to be based, mainly, on the lattice structure. All crystals of pure metals which crystallize in the same system possess the same crystal planes and crystal directions as sliding elements. This gives a basis for the determination of mechanical properties and the possibility of refining. 3 possibilities for increasing the strength of metals exist: (1) densifying (by compressing); (2) refining of the grain; (3) formation of solid solutions. These methods are discussed in detail and alloying by rolling and casting are described and the diagrams of state are illustrated. The nature of hardening, corroding and the formation of protective surfaces are also considered and explained in the light of the present state of knowledge. Many details are not yet satisfactorily explained, but still require extensive systematic research. 38 references supplement the article. Ha(2)

PROPERTIES OF FERROUS ALLOYS (3)

Comparative Physical Properties of Cr-Ni, Cr-Mn and Mn Steels. C. L. Clark & A. E. White. *Transactions American Society Mechanical Engineers*, Vol. 53, May–Aug. 1931, *Fuels & Steam Power*, pages 177–182.
With discussion. The paper gives the results of short-time tensile tests at 75 and 1000° F. and creep tests at 1000° F. on selected steels of the types named in the title, where Si and W are present. The tests are described and the results indicate that the substitution of Mn for Ni in Cr-Ni steels is detrimental, at least in so far as the load carrying ability of the alloy is concerned. While the creep resistance of the Mn and Mn-W steel at 1000° F. is superior to that of many pearlitic steels, it is not equal to that of Enduro KA2 type of alloy which contains only Cr and Ni. The 14% Mn steels possess properties comparable to those of the Cr-Mn steel, while the addition of W was found to increase its resistance to a marked degree. Ha(3)

The Influence of Rolling-In of Pipes on Ordinary Boiler Plate and on Izett-Plate. (Der Einfluss des Einwalzens von Röhren auf gewöhnliches Kesselblech und auf Izett-blech.) O. Bauer & H. Arndt. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 10, 1930, pages 48–53.
Both kinds of plates of known mechanical and structural qualities were drilled for taking up the fire tubes and the changes that had occurred were investigated. With regard to structural conditions, the 2 plates did not show any pronounced difference. Notch-tests show the Izett-plate (Krupp) to be superior to the other plate, the notch toughness being almost the same as for the full material after the tubes had been rolled-in. Aging through annealing effects a decrease of notch-toughness in both; but the Izett-plate is greatly superior (11 mkg./cm.²) to the ordinary plates (less than 4 mkg./cm.²). Ha(3)

Workability of Killed and Rimmed Steel. (Ein Beitrag zur Frage der Verarbeitbarkeit von beruhigtem und unberuhigtem Stahl.) P. Bardenheuer & H. Wünnenberg. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 13, No. 4, 1931, *Report* No. 174, pages 63–77; *Stahl und Eisen*, Vol. 51, May 21, 1931, page 651.
The effect of steel making upon workability was studied on 6 heats of about 0.1% C melted in a high frequency furnace and deoxidized and finished as follows: No. 1: Mn deoxidized, Al killed, alloyed, 0.2% Si; No. 2: Mn deoxidized, alloyed, 0.2% Si; No. 3: Mn deoxidized, killed with Si; No. 4: Si deoxidized, alloyed, 0.2% Si; No. 5: Al deoxidized, alloyed, 0.1% Al; No. 6: Mn deoxidized. The ingots were in part forged to take samples for physical tests, in part rolled to rods and subsequently drawn to wire, and in part rolled to hoops. The results of tensile tests, aging tests and comparison tests do not allow definite conclusions to be drawn as to the workability. The rolling and drawing tests indicate a better workability of the rimmed steel. The differences are, however, of a minor nature. The ingots with a rough surface could be better worked than those with smooth surface. It is noticed that the conditions of working, deformation velocity, shape of tool, lubrication and other factors have an important bearing upon the workability of steels finished by various methods. GN(3)

Strength and Wall-Thickness of Cast Iron. (Festigkeit und Wandstärke bei Gusseisen.) Paul A. Heller. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Mar. 20, 1931, pages 237–241.
The literature on relation between strength and wall-thickness is reviewed and critically discussed. The test results of different authors are compared. This comparison leads to the belief in the existence of several groups of cast iron types of equal strength relations and the probability that these relations can be represented in a diagram of strength over wall-thickness. 28 references. Ha(3)

Recent Developments in Special Iron. A. B. Everest. *Foundry Trade Journal*, Vol. 44, May 21, 1931, pages 355–358.
After discussing the metallography of cast Fe, the author deals with the limitations of the material and with methods which may be adopted to control the nature of the material during the melting operation. Recent developments in methods of manufacturing cast Fe are discussed and some attention is given to the use of alloy additions. Martensitic and austenitic irons are dealt with, and the mechanical properties of heat-treated alloy cast Fe are also noted. Space is devoted to the discussion of this paper and to the author's reply. OWE(3)

Properties and Fabrication of Stainless Steels. (Communications sur les relations entre les propriétés et la fabrication des aciers inoxydables.) E. Houdremont. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 181–199; *Aciers Spéciaux, Métaux et Alliages*, Vol. 6, Mar. 1931, pages 110–125.
Includes discussion and 47 figures. Very complete résumé of history, equilibria, melting practice, hot and cold working, weldability, recrystallization, corrosion resistance, intercrystalline attack, physical properties and structure of the Cr-Ni stainless steels. Most of the information is available elsewhere, but is conveniently collected here. Houdremont states that 18-8 can take up a "dangerous amount" of N up to 0.20% from the air on melting. This is said to be a characteristic of the steels high in Cr. See also *Metals & Alloys*, Vol. 2, Mar. 1931, page 63. HWG+GTM(3)

Recent Developments in Corrosion- and Heat-Resisting Steels. Robert Hadfield, T. G. Elliot & R. J. Sarjant. *Journal Society Chemical Industry*, Vol. 49, Jan. 24, 1930, pages 41–51.
A review of primarily Cr and Cr-Ni type steels covering their history; corrosion resistance in acid, atmosphere and sea water; mechanical and physical properties; microstructure; heat-resistance; and industrial applications. VVK(3)

Industrial Steels and Alloys—Recent Developments. Part 1. Steels for Strength, Corrosion and Machining. J. W. Donaldson. *Journal Society Chemical Industry*, Vol. 50, Sept. 25, 1931, pages 787–793.
A general review of C and alloy steels, their types and applications. VVK(3)

The Manufacture and Testing of Forging Quality Steel. N. L. Deuble. *Heat Treating & Forging*, Vol. 17, Sept. 1931, pages 864–869.
The requirements for low C steels which are to be used for forged products are discussed and methods of testing their qualities are described. Ha(3)

Cold Working Followed by Annealing. Robt. L. Geruso. *Heat Treating & Forging*, Vol. 17, Feb. 1931, pages 139–142.
A study of the effect on the physical properties of 0.22% C and 0.89% Mn steel reveals the fact that the physical properties of cold worked steel are altered by annealing at low temperature; that the ultimate strength as well as the yield point is raised, the former attaining its maximum on annealing at 300° C., while the latter attains its maximum when at 200° C. The toughness of this steel was lowered about 23% if cold working from 12 to 20% was followed by annealing from about 150° to 250° C. The notched-bar toughness is relatively high. The hardness of such cold worked steel can be increased by low-temperature annealing from 200° to 400° C. In all cases, the hardness of the steel, regardless of the amount of cold work, will be lowered on annealing above 500° C. Bend and notch-impact tests prove that the usual toughness of cold worked steel is reduced on annealing below 300° C. The critical temperatures vary according to the degree of cold working. Ha(3)

New Permalloys. G. W. Elmen. *Bell Laboratories Record*, Vol. 10, Sept. 1931, pages 2–5.
Permalloy containing 78.5% Ni and 21.5% Fe was tested to increase its usefulness in alternating current circuits by giving it a higher resistivity and also to simplify its heat treatment. The addition of either Cr or Mo accomplished the first purpose and also tends to increase the initial permeability. The addition of 3–5% caused an appreciable effect in this direction. Characteristic curves and data on heat treatment and Curie point (at which the material becomes nonmagnetic) are given. Permalloy is particularly useful in telephone circuits and instruments. Ha(3)

Some Physical Properties of High Speed Steel. Joseph V. Emmons (Cleveland Twist Drill Co.). *American Society for Steel Treating, Preprint* No. 22, 1931, 30 pages.
Paper to be read and discussed before the Boston Convention of the Society in Sept. 1931. 8 references are made to the literature and the paper is illustrated by numerous graphs and micrographs of high speed steel structures. The study of the common 18-4-1 type of high speed steel reported shows a measurable plasticity in hardened high speed steel at all heat treatments which appears to be governed largely by the troostite content of the structure. Martensite contributes high strength to which a small amount of troostite and accompanying plasticity gives better distribution of stresses. Variations in the amount of carbide taken into solution results in 3 types of martensite: low C type reverting to troostite at low drawing temperatures; high C content type decomposed only at high drawing temperatures; secondary martensite resulting from the decomposition of austenite on drawing. The indefinite property of toughness is analyzed and evaluated numerically. Martensite gives the hardness which is decreased by the presence of austenite and troostite. WLC(3)

Properties of Hardened Tool Steel. J. V. Emmons. *Heat Treating & Forging*, Vol. 17, Sept. 1931, pages 880–882; Oct. 1931, pages 961–964.
A detailed story of tests of tool steel with regard to hardness, toughness, tensile strength and torsional strength. 14 references. See *Metals & Alloys*, Vol. 2, Oct. 1931, page 205. Ha(3)

"Migra-Iron," a New Special Pig Iron for High Quality Casting. (Ueber "Migra-Eisen," ein neues Specialroheisen für hochwertigen Guss.) E. Piwowarsky & A. Wirtz. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Sept. 4, 1931, pages 703–705.
Migra iron is obtained from iron by the usual melting in the blast furnace but which, before casting into pigs, is subject to a special heat treatment in large refining tanks. This heat treatment consists of an overheating of definite duration and temperature and results in a remarkable fine grain and formation of graphite from which the name Migra (micro-graphite) is taken. This iron is used where a high machinability, easy pouring and high density is required with simultaneously good mechanical properties. It can also be used instead of charcoal pig iron for chill casting, roll castings and ingot molds. Microphotographs illustrate the difference in structures at the different stages of treatment. Ha(3)

A Few Recent Advancements in Tool Steels. (Einige Neuerungen auf dem Gebeite der Werkzeugstähle.) F. Rapatz. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, July 25, 1931, pages 965–968.
The conceptions of hardness and toughness are explained and an investigation made to note the way in which these properties can be determined numerically. Their dependence on the C contents and temperature is shown in curves and the progress made illustrated on tools for cold impact, cold drawing, threading, hot working tools, high speed tools and cutting metals. Ha(3)

On the Distribution of the Tensile Properties in Rolled Steel Shapes. (Ueber die Verteilung der Festigkeitseigenschaften in gewalzten Stahlprofilen.) F. Sauerwald, E. Seemann, F. Rögner & H. Müller. *Archiv für Eisenhüttenwesen*, Vol. 4, Mar. 1931, pages 431–434; *Stahl und Eisen*, Vol. 51, Apr. 30, 1931, pages 554–555.
Differences of the properties in various parts of a steel section may be due to (1) non-uniform composition of the material; (2) inner stresses; (3) non-uniformly distributed strain hardening; (4) non-uniform structure. The authors tested rails, T, double T and U shapes. The tensile strength was found to be higher in the web than in the other parts. Also the hardness is generally the highest in the web. In testing the rails, larger fluctuations of the hardness were observed in the web than in the head and the foot. The parts of the web close to head and foot showed a higher hardness than the middle of the web. There were only a few segregations in the rails tested but pronounced segregations in the other shapes tested. The outer zones of rounds and squares are softer than the core. The hardness generally decreases in heating to 600°, 770° and 780° C. In heating rails, the hardness of the web decreases more than that of head and foot. The results on the rails indicate that the differences of the properties are due to a non-uniform strain hardening but in the other shapes they are due to variations of the composition. The distribution of hardness of cold worked and recrystallized rounds was also studied. GN(3)

The Mechanical Properties of Open Hearth and Bessemer Steel Rails. (Die mechanischen Eigenschaften von Siemens-Martin- und Bessemer-Stahlschienen.) W. N. Swetschnikoff. *Stahl und Eisen*, Vol. 51, Aug. 20, 1931, pages 1065–1066.
Abstract of a paper by the same author in *Ugoli i Jeleso*, 1930, pages 60–67. The results of this statistical research indicate that Bessemer rails have a higher tensile strength, limit of elasticity and limit of proportionality, and, in part, also a higher elongation than open-hearth rails. The differences are due to the production methods and, therefore, due to the chemical composition. Bessemer rails are made of steel containing 0.10%–0.15% less C than open hearth rails; but the P and N_2 content is higher. GN(3)

Rustproof, Austenitic Materials for Nozzles of Steam Turbines. (Rostfreie austenitische Schaufelwerkstoffe für Dampfturbinen.) H. Schottky & E. Houdremont. *Krupp'sche Monatshefte*, Vol. 12, July 1931, pages 188–194.
After a short historical review of the development of austenitic steels, the Ni steel type V5M was developed. This steel not only possesses the required strength and hardness, but also good workability; its analysis is 0.1–0.15% C, 12% Cr, 0.7% Ni. It has a tensile strength of 70 kg./mm.², elastic limit of 48 kg./mm.², bending vibration strength of 36 kg./mm.² 2 other types of steel, WF100 and NCT4, have been developed (but not yet used) and promise very well for use, particularly as nozzle material. 8 references. Chromium Iron Alloys Have Remarkable Properties. Charles A. Scharschu (Allegheny Steel Co.). *Metal Progress*, Vol. 20, July 1931, pages 59–63.
Continuation of article appearing in May issue discusses the fabrication, welding, drawing, pressing and applications of low carbon chromium iron alloys. WLC(3)

Stainless Steel and Its Properties. Earl Smith. *Heat Treating & Forging*, Vol. 16, Nov. 1930, pages 1403–1405, 1408.
The physical and chemical characteristics of this steel are fully described and its treatment, according to the purpose for which it is intended, is discussed. The properly treated Cr-Ni-irons are austenitic, non-magnetic and single phase solid solutions. By cold working, they become magnetic. Ha(3)

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Losses from the Corrosion of Underground Piping. E. R. SHEPARD. *Gas Age Record*, Vol. 68, Sept. 5, 1931, pages 333, 350.

Any attempt to estimate the annual loss from corrosion of underground piping systems is obviously a speculative enterprise. The round figure of one hundred million dollars which has been named at various times as the annual loss from corrosion to the petroleum industry, which amounts roughly to one cent/gal. of gasoline produced, is based on a summary of replies to the American Petroleum Institute corrosion committee questionnaire, as prepared by F. N. Speller and E. L. Chappell in 1927. These figures include corrosion on production, transportation and refining equipment, but apply only to the petroleum industry. For the pipe lines alone, an average annual loss from corrosion of \$308/mi./yr. was arrived at. The pipe line maps published in the *Oil & Gas Journal*, June 4, 1931, show approximately 109,800 mi. of trunk and gathering lines used for the transportation of oil and gasoline, and approximately 65,000 miles of natural gas pipe lines in the United States. An average figure of \$7000/mi. a normal cost for an 8-inch oil line, will be employed in this estimate. The average size of natural gas lines is something larger than that of oil lines, and a unit cost of \$12,000/mi. will be used for these lines. Many of the larger lines cost more than double that amount. Using the above unit costs and lengths, we have the following summary of values:

109,800 mi. of oil and gas lines at \$7000	\$768,600,000
65,000 mi. of natural gas lines at \$12,000	780,000,000
138,000 mi. of gas distributing mains at \$15,000	2,070,000,000
138,000 mi. of water distributing mains at \$15,000	2,070,000,000
Total	\$5,688,600,000

It requires an annual depreciation of only 2.5% to arrive at a figure of \$142,-215,000 as the annual loss to underground piping systems chargeable to soil corrosion. This value for depreciation, which represents an average life of 40 yrs., is in line with Speller's value of \$308/mi./yr., which is approximately 3% on a valuation of \$10,000/mi. This figure is obviously too high for some cases, but too low for other cases. Cast iron mains in cities will last longer than 40 yrs., while many other types of pipe lines must be serviced or replaced after a period of 10 to 30 yrs. To this must be added the value of lost oil and gas, damage to crops and other property, interruption of service, and other expenses incidental to corrosion damage. Approximately \$50,000 is expended annually by the Bureau of Standards, the American Petroleum Institute, the American Gas Association, and the Cast Iron Pipe Research Association, for a scientific study of the corrosion problem and methods of prevention. This is but slightly more than 1/30 of 1% of the estimated annual corrosion loss to the piping systems of the country. WAT(4)

Value of Cadmium as a Corrosion Preventative for Copper, Brass and Bronze. GUSTAF SODERBERG. *Metal Cleaning & Finishing*, Vol. 2, Dec. 1930, pages 1017–1022.

Cd alloys with brass, especially high Zn brass, and with bronze at ordinary room temperatures. Cu and Cd alloy only at temperatures above 212° F. Coatings less than .00005 in. thick are absorbed by brass in a couple of months. Electrochemical protection of Cu and its alloys by Cd is more pronounced than the same protection of steel. Corrosion resistance of Cd plating increases approximately with the square of the thickness of the plate. Thickness of 0.00015 in. is a minimum on Fe and steel for satisfactory rust resistances. Standards require 0.0002 in. on steel for normal conditions and as high as 0.0004 in. for severe conditions. Army specifications call for 0.0003 in. Cd. In the case of Cu and its alloys, these figures should be increased 50% for equal protection. Improper cleaning is responsible for about 95% of the troubles in plating. Special mild cleaners developed for Cu, brass and bronze should be used. Temperature should be 180–200° F. and the current density, 40–50 amp./ft.^{2}. Tarnish is removed in a 50:50 HCl dip. For removal of black oxide scale, 5–10% H_2SO_4 is used. This is used cold on yellow brass, but the temperature may be 150° F. in pickling brass containing less than 20% Zn. Red spots of Cu_2O may be removed by HNO_3. Recommends bright dipping in a solution containing in 25 gals. H_2SO_4, 11 gal., HNO_3, 2 gal., HCl, 1 pt., H_2O, 12 gal. Cd-plated brass parts of electrical apparatus often become rapidly covered with a non-adherent white powder on exposure to a tropical climate. This corrosion product consists of water-soluble organic matter and is due to the presence of unsuitable electrical insulating materials. Cd plating of both brass and steel when these come in contact will prevent electrolysis. There is practically no action between hot-dipped Zn and Cd. Electrical resistance of Cu contacts increases greatly when the Cu is oxidized. Cu oxidizes readily at room temperatures, but Cd does not oxidize below 480° F. Also, electrical resistance of CdO is much less than that of CuO. Tests have shown that Cd plating of contacts operating under oxidizing conditions reduces the contact resistance. Parts which are not subjected to oxidation and which must operate within very small temperature intervals should not be Cd plated. MS(4)

The Behavior of Heat-Resistant Alloys toward Sulphur. (**Ueber das Verhalten hitzebeständiger Legierungen gegen Schwefel.**) A. SCHULZE. *Die Wärme*, Vol 53, Aug. 30, 1930, pages 662–663.

A report of the work of H. Gruber ("Anniversary of the seventieth birthday" of W. Heraeus, Hanau, 1930, page 45) on corrosion resistance of alloys to H_2S at high temperatures. The alloys studied were Cr-Fe, Cr-Ni-Fe, Cr-Ni, Cr-Ni-Mn, Al-Ni-Cr, Mn-Fe, Al-Ni, Al-Fe and Al-Cr-Fe at temperatures of 700–1000° C. The aluminum alloys showed the least attack. WHB(4)

Effect of Adding Colloids to Electrolytic Solutions for Preparing the Anodic Film on Aluminum. S. SATOH & A. MIYATA. *Scientific Papers Institute Physical & Chemical Research*, Tokyo, Supplement, Vol. 15, Dec. 24, 1930, 6 pages; *Journal Society Chemical Industry*, Vol. 50, April 17, 1931, page 352.

The electrolytic formation of protective films of oxide on an aluminum anode in 2% oxalic acid and also in 3% chromic acid has been studied. The addition of sodium silicate increases the anode potential and decreases the scratch-hardness of the film produced. The film obtained in the presence of sodium silicate is also less resistant to corrosion than that produced in its absence. WHB(4)

Corrosion Tests in Germany. GEORGE BOLDBACH. *Aircraft Engineering*, British, Vol. 3, Aug. 1931, pages 195–196.

Tentative standard methods laid down by the Aluminum Board of the Reichsauschuss für Metallschutz. In all corrosion tests, it should be noticed carefully that both the material and the attacking agent conform fully to service conditions. The chemical composition, the mechanical properties, and the previous treatment of the test material should be stated as far as possible. At least 3 specimens should be tested at once rather than each at different times. In order to compensate for unevenness, the area should be as large as possible. The specimens should be cleaned with light benzine or pure benzol or a mixture of both. Ether, acetone and the like should not be used on account of the cold produced by vaporization. The specimens should not be bored if it can be avoided, as the area of attack is increased. Cut edges should not be covered, for in severe attack the covering may be undermined and removed and the test unreliable. The points to be noted when testing the corrodibility are: (1) changes in the surface, (2) changes in the microstructure, (3) loss in weight, (4) changes in the mechanical properties, (5) nature and condition of the corrosion products. In total immersion tests the solution should be stirred. For Al and its alloys, a solution of 0.5 *N* (about 3%) sodium chloride and 0.1% hydrogen peroxide is recommended. This 0.1% hydrogen peroxide content should be kept up by suitable additions once a day. In alternate immersion tests the attacking agent should be chosen so that at least 6 cc. of the solution corresponds to 1 cm.^{2} of the submerged area. Salt spray tests are usually made in diffused daylight and with 0.5 N sodium chloride (about 3%). Weather exposure tests are made by use of adequate wooden frames, precautions being taken that no stains are produced on the samples. The frames should be erected facing south at an angle of 45° and be at least 50 cm. above ground. In all cases, care should be exercised that the suspension and insulation of the specimens conform to service conditions. The duration of tests should be in accordance with extent of the corrosive attack. WAT(4)

Metal-Corrosion Problems—The Stability of Thin Films. U. R. EVANS. *Chemical Trade Journal*, Vol. 89, Sept. 18, 1931, page 270.

Oxide films on metals are removed, almost generally, by dissolving th metal immediately below. The movement of electrode potential with time provides a valuable method of determining whether weak spots in natural oxide films are healing up or are extending. The method has been applied to show the self-healing qualities of the film present on the new Al-containing brass used for condenser tubes, also to the comparison of various steels containing Cr and/or Ni under different conditions of heat treatment and surface treatment. Influences destructive to protective films include "screening" from O, continual bending or abrasion or bombarding by air bubbles. Alternating stresses and corrosive influences cause damage more rapidly than either acting alone. WHB(4)

Corrosion of Aluminum Alloys. (**Studio sul problema della corrosione delle leghe di alluminio.**) J. DORNAUF. *Metalli Leggeri*, Vol. 1, May-June 1931, pages 41–44.

General comments with photographs of applications of Silumin to uses involving corrosion resistance. HWG(4)

Corrosion-Resisting Cast Iron. (**Korrosions beständiges Gusseisen.**) W. ACKERMAN. *Die Giesserei mit Giesserei-Zeitung*, Vol. 27, May 15, 1930, pages 263–266.

Since corrosion is an electrochemical process, the homogeneous structure of solid solutions is most favorable to resistance. Graphite accelerates corrosion. Si causes the precipitation of graphite but a cast iron with 0.84% Si corrodes more rapidly than one with 2.25% Si. The resistance of the higher Si casting is attributed not to the graphite but to the Si which is in the solid solution. P up to 0.5% increases the resistance, but more than 0.07% S is detrimental. From 14 to 22% Si creates an acid-resisting material which is not recommended for alkaline solutions. Ni, Cu and Cr reduce the rate of corrosion under certain conditions. The addition of Monel metal to cast iron produces an austenitic structure and increases the resistance to corrosion. Ha(4)

Some Factors Affecting the Corrosion of Buried Steel. F. L. BASSETT. *Journal Society Chemical Industry*, Vol. 50, May 8, 1931, pages 161–166T.

The author was consulted on the possible corrosion of a pipe line several hundred miles in length through the Iraq-Syrian desert. 80 samples of soil consisting of calcareous loams and clays, often sandy, gypsiferous or slightly salted were used in a preliminary survey. No acid soils were found in the series. Localized areas of acid soil, impregnated with free sulphuric acid, occur in the oil territory and springs of approximately 0.1 N sulphuric acid have been found. S and hydrogen sulphide are associated with the oil and bitumen seepages. Salt pans and salty ground are found in many of the shallow valleys and depressions of the desert. The conditions to be met were annual rainfall of about 8 ins. concentrated between November and March; a daily fluctuation of shade temperature of about 60° F.; and a seasonal fluctuation of more than 100° F. A 10 mile main of "rustless" iron had corroded badly, perforating in some places in 18 mos.; and ordinary steel mains had given similar but less severe trouble. Laboratory tests were organized as follows: 600 strips of steel 6 in. × 1 in. × 1 mm. were cut from pipes, one of British and the other of French manufacture, and finished to a uniform medium fine polish with No. 2 emery. The analyses of the steel were: "L," Mn 0.30–0.60%, P under 0.11%, S under 0.065%, C not given; "S", Mn 0.30–0.60%, P under 0.04%, S under 0.06%, C not given. The polished strips were half immersed vertically in the sifted (10 mesh) and well mixed soil previously wetted with 25% of water. Tests were run for 1, 2 and 3 mos. Specimens were cleaned by wire brushing. Partial analysis of 12 representative specimens of soil gave a range of composition of SiO_2 13.5–39.5%, Al_2O_3 4.2–14.2%, CaO 11.2–33.2%, MgO 2.6–9.0%, SO_3 0.5-7.0%. pH values on 80 samples gave a mean value of 8.0–8.2 with extremes of 7.5 in 2 cases and 8.5 in 2 others. Sand content ranged up to 24% in a few cases for "coarse sand" (0.2–1.0 mm.) and up to 36% for "fine sand" or "silt" (0.2–0.01 mm.). Detailed analyses are not given. The soils were classified according to chloride content and the results as summarized by the abstractor follow:

	One mo.'s exposure			Two mo.'s exposure			Three mo.'s exposure		
	% water retained at end	Corrosion loss of steels in g./dcm.^{2} "L"	"S"	% water retained at end	Corrosion loss of steels in g./dcm.^{2} "L"	"S"	% water retained at end	Corrosion loss of steels in g./dcm.^{2} "L"	"S"
Average of 10 soils with NaCl over 1%	18.23	0.303	0.251	17.52	0.570	0.529	12.14	0.807	0.769
Average of 7 soils NaCl 0.2–1%	16.53	0.403	0.373	16.34	0.644	0.593	9.03	1.089	0.931
Average of 16 soils with NaCl 0.005–0.2%	14.3	0.594	0.546	13.57	1.182	1.169	5.14	2.04	1.82
Average of 47 soils with NaCl "nil"	14.6	0.443	0.445	14.4	0.923	0.895	4.64	1.544	1.343
Synthetic soil consisting of fine sand initially saturated with 0.1 *N* NaCl		0.40	0.56	13.3	1.81	1.74	5.7	2.74	2.64

In all cases, the corrosion took the form of localized pitting. The most corrosive soils, apart from the highly salted specimens, were those of close and dense texture. The soils which had the greatest water retentivity showed, as a rule, the least corrosion of the steel. A chloride content from 0.2% upward corresponded with both an increase of water retentivity and a marked average decrease of corrosion. Maximum corrosive attack occurs in the group of slightly salted soils below 0.2%. Further tests, using nonsalty soils with the addition of sodium and calcium chlorides, are under way. VVK(4)

Thin Films in Relation to Corrosion Problems. U. R. EVANS (Cambridge University). *Institute of Metals, Advance Copy* No. 586, Sept. 1931, 17 pages.

The tenth Autumn lecture to the Institute of Metals, delivered Sept. 13, 1931 in Zürich. Discusses the influence of films on the corrosion of both ferrous and non-ferrous products. In both groups thin, invisible oxide layers have a predominant influence on corrosion. JLG(4)

The Corrosion of Metals. Part I. General Theory. WILH. PALMAER. Svenska Bokhandelscentralen A. B., Stockholm, 1929. Paper $6^{1}/_{2} \times 9^{1}/_{4}$ inches, 347 pages. Price 20 kronen.

The Corrosion of Metals by W. Palmaer is in three parts, of which Part I discusses the general theory, Part II will deal with special researches concerning the dissolving of metals and Part III will deal with the special theory of the corrosion of iron. Part II and Part III will be published shortly. The present 347 pages are confined to an exposition of the dissolving of metals in acids from the standpoint of the "theory of local galvanic elements" compared with the mass action and the diffusion theories. The primary factor when metals are dissolved in acids is the activity of local galvanic elements. The intensity of the local currents is affected by the same factors as have an influence upon the currents delivered by galvanic elements. Among these are diffusion and convection, which affect the concentration of the ions in the layer next to the cathodes and consequently the E. M. F., while the cases where the current intensity depends only upon diffusion and convection are rare. Since the formation of insoluble substances such as rust appearing in the corrosion proper at ordinary temperature, is in all probability preceded by a dissolving of the metal in question, one must suppose that the primary thing in corrosion also is the activity of local galvanic elements. This particular point will be taken up in Part III. From the viewpoint of "local galvanic elements," therefore, the velocity of dissolution of metals would be determined by the difference in the electromotive force with which the metal tends to enter into solution as ion and the electromotive counter-force which arises from the hydrogen deposited on the metal, by the specific electrical conductivity of the solution and by the resistance capacity of the local galvanic elements. The general quantitative expression for all cases of the dissolving or corrosion of metals is given as $\rho = f \cdot i$ or $\rho = f \cdot e \cdot \frac{x}{C}$ where ρ is the reaction velocity, f is a proportionality factor, the value of which is determined by the measure adopted for the reaction velocity, i the total intensity of the local currents, e the electromotive force of the local elements, x the specific electrical conductivity of the solution and C the resistance capacity of the local elements. Some very comprehensive data on the solution of aluminum and of a gray pig iron in hydrochloric acid are given and discussed. The argument of the author for the existence of local galvanic elements is well substantiated. However after 347 pages of data and discussion a few pages devoted to a concise clear statement of exactly the facts produced and a brief interpretation of them would be welcomed. Otherwise the reader is liable to feel somewhat muddled unless he very laboriously digs out the information he wants. Since, however, some very important points are to be discussed in the following Part II and Part III perhaps we can expect some such summary when the other parts are finished. The translation is adequate but could be considerably improved by better sentence construction and a more careful choice of words. —V. V. Kendall (4)-**B**-

Seasonal Variation in Rate of Impingement Corrosion. ALAN MORRIS. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 431, Sept. 1931, 9 pages.

Tests extending over about 2 years have shown that the rate of impingement corrosion varies with the seasons; the attack is most rapid during the summer months. The water used was taken from the Penguonnock river at Bridgeport, Conn. The test method used was similar to that described by Bengough, May and Pirret. The corrosion of Admiralty metal was greater than that for nickel silver, the expected rates being 1.2 and 0.9 mils/100 hr., respectively. Contains 4 references. JLG(4)

Effect of Physical State of Small Amounts of Copper upon the Rate of Corrosion of Lead by Sulfuric Acid. E. G. MAHIN & E. J. WILHELM. *Industrial & Engineering Chemistry*, Vol. 22, Dec. 1930, pages 1397–1404.

It is shown that rapidly cooled lead is improved in its resistance to attack by sulphuric acid, by addition of copper up to 1%, but that, if its practical application involves continued heating, even at a temperature of 100° C., the copper falls out of solid solution and it then may accelerate the acid attack. Under such heating conditions, copper up to 0.20% improves the qualities of lead, but beyond this limit it promotes destruction of the sheet by the acid. 24 references. This paper was presented before the Division of Industrial and Engineering Chemistry of the American Chemical Society at the Sept. meeting, 1930. MEH(4)

The Corrosion of Cans. T. H. MORRIS & J. M. BRYAN. *Food Manufacture*, London, Vol. 6, No. 4, 1931, pages 100–102.

Fe, Sn, Sn-Fe couples and Sn plate were immersed in 0.5% citric acid containing Na citrate to regulate the pH in the presence and absence of air. O_2 increased corrosion of Fe at low acidities more than at high acidities. Sn was not attacked by non-oxidizing organic acids but was quite readily attacked when O_2 was present. Sn-Fe couples and Sn plate were quite similar in behavior in that (1) Sn salts in the solution reduced the corrosion of Fe; (2) Sn was attacked slowly even in the absence of air and especially at pH's from 4 to 5.5; (3) H_2 was evolved from the iron surface and this was attributed to the high over-potential of H_2 on Sn; (4) there is a reversal of potential, Fe is anodic at first; (5) if Sn corroded rapidly, Fe corroded slowly and vice versa. Substances present in unrefined beet sugar, beet sugar and agar-agar, and inverted cane sugar were found to have inhibitive properties, the first on corrosion of Fe; the second on Fe and Sn and the third on Sn. SO_2 accelerated the corrosion of Fe at a pH of 2.4 and retarded it at 5.5. SO_2 makes the Fe permanently anodic to Sn since a film of Sn sulphide forms on the Sn. WHB(4)

The Effect of Artificial Ageing upon the Resistance of Super-Duralumin to Corrosion by Sea-Water. K. L. MEISSNER. *Journal Institute of Metals*, Vol. 45, no. 1, 1931, pages 187–208; abstracted in *Engineer*, Vol. 151, Apr. 3, 1931, pages 373–374.

Includes discussion. See *Metals & Alloys*, Vol. 2, July 1931, page 128. LFM(4)

On the Chemical Reaction between Metallic Magnesium and Aqueous Chloride Solutions. JITAKA. *Proceedings Imperial Academy*, Tokio, Vol. 6, No. 9, 1930, pages 363–366.

The particular behavior of Mg in Cl solutions in which, contrary to its behavior in other solutions, Mg is quickly destroyed was thoroughly investigated and the dependency from the H ion concentration determined. The following ranges of reaction are stated for Mg: (1) If H' is less than 10^{-4}, a vivid dissolution of the metal takes place. The velocity of reaction increases with the reduction of H ions. (2) In the range from $H' = 10^{-4}$ to 10^{-11}, the velocity of reaction remains constant; it is now independent of the concentration of H ions. The dissolution forms films which, in time, act as protection. Stirring reduces the reaction velocity. (3) From $H' = 10^{-11}$ to 10^{-14}, the reaction velocity decreases, due to greater viscosity of the solution. In solutions above 10^{-3}, the Cl ions are able to break the protective film but due to the low concentration of H ions, the reaction is not accelerated thereby. Ha(4)

Pure Iron and Its Application in the Gas Industry. M. A. REYNAUD. *Gas Journal*, Vol. 194, June 10, 1931, pages 831–832.

Review of paper presented before the Annual Congress of the Association Technique de l'Industrie du Gaz en France, April 21 to 25, 1931. The causes responsible for the corrosion of iron and steel are discussed and referred to the fact that present-day steel is much more readily corroded than puddled iron, which had its immunity due to its chemical homogeneity and to low content of Mn and S. The homogeneity of chemical composition and physical condition and of uniformity of aeration was emphasized. MAB(4)

Increasing business throughout the middle western section has necessitated the recent opening of a factory branch office in Chicago by the **Alloy Metal Wire Co.**, Moore, Pa. The new office at 504 Produce Exchange Bldg., 14th and Racine Sts., has been placed in charge of Mr. R. L. Howe, formerly with the Truscon Steel Company.

Lancaster, Allwine & Rommel announce the removal on December 1, 1931, of their patent law offices to 815 Fifteenth Street, N. W., Washington, D. C.

The Corrosion of Power Plant Equipment by Flue Gases. Henry Fraser Johnstone. *University of Illinois Engineering Experiment Station Bulletin* No. 228, June 1931, 120 pages.
The work carried out in the investigation was done in coöperation with 7 power companies in and about Chicago. The investigation so far has been of a technical nature and no attempt has been made to try out new features of operation under plant conditions. It has been the general object first to find out what the factors are that are contributing most to corrosion, and then to study methods of their elimination or the prevention by some other means. The conditions which are prevalent in flue gases that cause corrosion and some of the steps that may be taken toward their elimination are described. The reactions that take place in a boiler furnace are discussed and their effect on corrosion and slag formation are brought out. A description of the experimental work carried on in the laboratory on corrosion and its results are also presented. These substantiate the ideas of the cause of the corrosion suggested by the plant data. The results of tests on various corrosion-resistant alloys and protective coatings under the conditions existing in the flue gases are reported. A description is also given of new methods for the determination of the dew-point and sulphur dioxide and trioxide concentrations in flue gases. Finally, a discussion of the fundamental corrosion reactions is made in order that the work reported may be carried forward by others who may be interested in this field. Many tables and illustrations of typical examples of corrosion are presented. WAT(4)

The Corrosion of Metals. H. Sutton. *Aircraft Engineering,* Vol. 2, Aug. 1930, pages 209–210.
Intercrystalline corrosion of duralumin is reduced to a minimum when the alloy is heat treated at a high temperature, quenched in cold water and allowed to age at normal temperature. Although rapid aging at elevated temperatures is sometimes used for producing high strength Al alloys, such practice has a harmful effect on corrosion resistance. Cold working increases slightly the corrosion tendency. The anodic oxidation process, in which an adherent film of oxide is produced by electrolytic oxidation of Al alloys in chromic acid solution, is valuable for protection of aircraft parts and also to show imperfections in the metal. Mg alloys, Cr-Ni steels and ordinary steels protected by oils, enamels, ZnO and Al paints are also used in the aircraft industry. (4)

Rust Prevention during Shutdowns. Bernard Jeffs. *Iron & Steel o Canada,* Vol. 14, Mar. 1931, page 51.
An excerpt from Houghton's "Black and White," in which special attention is directed to the fact that lubricating oils, petrolatum and similar compounds lack the necessary properties for preventing rusting of machinery. Methods which may be adopted to bring about the necessary effects are described. See *Metals & Alloys,* Oct. 1931, page 207. OWE(4)

The Use of Aluminum for Oil Lease Tanks. Part II. Laboratory Tests. Ludwig Schmidt, John M. Devine & C. J. Wilhelm. *United States Bureau of Mines, Report of Investigations* No. 3131, Oct. 1931, 16 pages.
Low-temperature salt-water corrosion of Al tank sheets in contact with natural brine was primarily caused by the $MgCl_2$ and $CaCl_2$ in the brine. FeS or O greatly accelerated the corrosion. High-temperature corrosion (Al steam coils) was caused primarily by the precipitation of bubbles of H_2S or CO_2 on the surface of the metal. Bimetallic corrosion, which was encountered where Al-steel contacts existed in the presence of brine, is explained by the relatively anodic character of Al as compared to steel. Different grades of commercial Al vary in their resistance to the types of corrosion studied. AHE(4)

The Corrosion of Metals. Alfred Stansfield. *Engineering Journal,* Vol. 14, Aug. 1931, pages 444–446.
Freedom from corrosion may be approximated by having the metals pure or by having the constituents of the metal homogeneous. Electrolytic Fe is not readily attacked, being perfectly pure and homogeneous. Some electrolysis will take place, however, due to the fact that the orientation of the atoms in the different grains will be in different directions. Even if the metal is homogeneous, corrosion can occur through differing compositions at different parts or by difference in O concentration. Examples and photomicrographs are given. VVK(4)

Effect of Steaming on the Life of the Extractors of Glover-West Retorts. M. H. Seramme. *Gas Journal,* Vol. 194, June 10, 1931, page 832.
Reviews paper presented before the Annual Congress of the Association Technique de l'Industrie du Gaz en France, April 21 to 25, 1931. Fracture occurs first in the hottest retorts and may become apparent after a life of 44 to 52 mos. It is due to growth of the cast iron leading to development of porosity and resulting oxidation, as a result of high temperature. The use of a special alloy, e. g., one of Bi-Cu-Cr is suggested. MAB(4)

The Protection of Magnesium Alloys against Corrosion. H. Sutton & L. F. LeBrocq (Royal Aircraft Establishment). *Institute of Metals, Advance Copy* No. 583, Sept. 1931, 20 pages.
The addition of 1.85% Mn to Mg slightly increased its resistance to the sea water corrosion test, but not sufficient to warrant the use of this alloy. Other methods of increasing the corrosion resistance of Mg, including sherardizing, calorizing, metal spraying, anodic treatment, cathodic treatment and chemical treatment were studied. The best resistance was obtained by chemical treatment. Actual tests proved that after a treatment with a chromate bath the metal was resistant to all but the most corrosive marine conditions. A lanolin coating after this treatment is recommended. Prior to this treatment parts can be cleaned by a 10% nitric acid treatment if fine tolerances are not demanded, but where little material can be removed, cleaning can be done with a 2% caustic soda solution. Sand blasting is not recommended. Additional protection can be obtained by coating the surface after chromate treatment with a cellulose enamel. Contains 4 references. JLG(4)

Investigation of Materials to Reduce Steam Turbine Blade Wear. J. L. Ray. *Power,* Vol. 73, May 26, 1931, page 804.
A general discussion of erosion of turbine blades by steam is presented. Steam turbine blading has been and continues to be one of the main sources of operating trouble. Although wear has never been excessive, it has necessitated enough blade replacement to justify the researches made to reduce or eliminate it. Laboratory tests are not satisfactory; the material must be subjected to actual service tests. The following materials are discussed in a general way although the results of no actual tests are given: stainless iron, 5% Ni steel, an alloy of 36% Ni and 12% Cr, pure W, pure Ta, stellite, an alloy of 60% Ni and 15% Cr, an 18% Cr-8% Ni steel and Nitralloy. A number of photographs are presented which show the type of erosion produced by steam on a number of the alloys mentioned above. WAT(4)

Exterior Protection of Metal Tubes against Corrosion. (La protection extérieure des tuyaux métalliques contre la corrosion.) A. Rocca. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 419–428; *Metallbörse,* Vol. 20, Aug. 16, 1930, page 1829.
Deals with bituminous and cement coatings, especially with a particular coating sold under the trade name, "Dalmine." See also *Metals & Alloys,* Vol. 2, Jan. 1931, page 2. HWG(4)

STRUCTURE OF METALS & ALLOYS (5)

Metallography & Macrography (5a)

Alloys of Iron Research. Part X. The Chromium-Iron Constitutional Diagram. FRANK ADCOCK (National Physical Laboratory.) *Iron & Steel Institute, Advance Copy* No. 2, Sept. 1931, 48 pages.

Bibliography of 34 references. Previous work on the Fe–Cr system is reviewed. Alloys were prepared from metals of high purity, and the entire series of alloys was carefully studied. The materials were melted in thoria-lined alumina crucibles in vacuo. Freezing point temperatures were obtained by thermocouples for the Fe-rich alloys, and by an optical pyrometer for the Cr-rich alloys. Thermal, dilatometric, microscopic and magnetic methods were used in determining the transformations in the solid. The melting point of Cr was found to be 1830° C. Fe-Cr alloys form a continuous series of solid solutions, with a minimum melting point of about 1500° C. at 20% Cr. (Unless otherwise stated all compositions are in atomic percentages.) The γ loop extends to 11.6 wt. % Cr. As Cr is added to Fe, the A_3 temperature is lowered to a minimum at about 8% Cr, after which it rises to meet the lowered A_4 transformation. The magnetic transformation temperature is lowered with increasing Cr until at about 70% Cr it occurs in the neighborhood of atmospheric temperatures. In alloys containing about 40–70% Cr the magnetic transformation is dependent on the previous thermal history of the alloys. The Brinell hardness-composition curve of the annealed alloys has a maximum hardness value of 345 at 75 % Cr. The electric resistance-composition curve is of the inverted U type characteristic of a continuous series of solid solutions. Density-composition and lattice parameter-composition curves are also given. They are not straight lines. Values of magnetic induction for several magnetizing forces are given for the alloys containing less than 70% Cr. JLG(5a)

The Equilibrium of Certain Non-Metallic Systems. Part I.—The Equilibrium of the System FeO–MnO. Part II.—The Equilibrium of the Systems MnS–MnO, MnS–$MnSiO_3$ and $MnSiO_4$. J. H. ANDREW, W. R. MADDOCKS &. E. A. FOWLER. (Technical College, Glasgow.) *Iron & Steel Institute Advance Copy* No. 1, Sept. 1931, 26 pages.

Pure FeO was prepared by heating ferrous oxalate in vacuo at 700° C. This material analyzed at least 99.5% FeO, and its melting point was found to be 1410° C. MnO was prepared by heating manganese oxalate at 850° C. in vacuo. Its melting point was 1585° C. Equilibrium in the FeO–MnO system, and other systems, was studied thermally and by means of microscopic examination. FeO and MnO form a continuous series of solid solutions. MnS, 99.8% pure, was obtained by passing H_2S over chemically prepared MnS at a temperature of 850° C. In the MnO–MnS system a eutectic is formed at about 50% MnO and 1280° C. $MnSiO_3$ was prepared by fusing pure MnO with sand. In the $MnSiO_3$–MnS system a eutectic is formed at about 10% MnS and 1250° C. About 1.5% MnS is soluble in the solid silicate and about 1.3% of the silicate is soluble in MnS. Fe_2SiO_4 was prepared by fusing pure FeO with sand. In the Fe_2SiO_4–MnS system a eutectic occurs at 10% MnS and 1060° C. A small solid solubility (1 or 2%) is found at both ends of the diagram. The sulphide-silicate inclusions found in steel probably melt below the forging temperature, but the fact that they ball up rather than surround the grains explains why they do not render ordinary steel unforgeable. As an appreciable amount of MnS is soluble in oxide inclusions the spots shown on sulphur prints are probably indicative of oxide inclusions, and are not caused by purely sulphide particles. 7 references. JLG(5a)

Identification of Inclusions in Steels. LELAND E. GRANT. *American Society for Steel Treating, Preprint* No. 29, 1931, 14 pages.

Paper read and discussed before the Boston Convention of the Society in Sept. 1931. 7 references are cited. 21 micrographs illustrate the heterogeneity of inclusions in steels. The examination of inclusions with the usual identifying etching reagents is not entirely adequate to the study of the various phases present in non-homogeneous inclusions. The development of more selective reagents is required for this study. WLC(5a)

Effect of Heat Treatment upon Ferrite Banding in Steel. WILBER E. HARVEY & BRADLEY STOUGHTON (Lehigh University). *American Society for Steel Treating, Preprint* No. 30, 1931, 8 pages.

Paper read and discussed before the Boston Convention of the Society in Sept. 1931. The authors show in 15 micrographs the results of their study of heat treatments for the elimination or reduction of ferrite banding. Long heating above the Ac_3 point followed by water quench and subsequent drawing or cooling in air after such heating entirely eliminates this structure. Cooling in the furnace greatly improves the structure. WLC(5a)

Submicroscopic Inclusions in Steel. C. H. HERTY, JR. (Pittsburgh Station, U. S. Bureau of Mines). *Metal Progress*, Vol. 20, Oct. 1931, pages 37–42.

Extracts from the Sixth Campbell Memorial Lecture delivered before the American Society for Steel Treating in its Boston Convention, Sept. 1931. The author divides non-metallic matter into particles visible at 250 ×, smaller inclusions, and solid solution material. Evidence of a slight solubility of liquid steel for SiO_2 is presented. The association of ferrite banding with stringers of certain types of inclusions and absence of such association with other types of inclusions is shown. Macrophotographs are given illustrating these points. The relation of internal seams to the method of deoxidation of the steel is discussed. WLC(5a)

The Structures of the High-Chromium Stainless Steels and Irons. EDGAR C. BAIN. *Heat Treating & Forging*, Vol. 16, Nov. 1930, pages 1419–1426.

The paper gives a compilation and interpretation of some of the structures found in high Cr non-corroding alloys. The properties are very closely dependent on the structure of the metal; therefore, its observation affords a convenient method of recognition and control of the properties to be developed industrially. For each purpose, an alloy of definite properties will be best suited. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 34. Ha(5a)

Investigations into the Influence of the Composition of the Slag on the Structure of Gray Iron Alloys. (Untersuchungen über den Einfluss der Schlackenzusammensetzung auf das Gefüge grauer Eisenlegierungen.) E. DIEPSCHLAG & L. TREUHEIT. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Sept. 4, 1931, pages 705–710.

On the basis of melting experiments in lined graphite crucibles, an influence of silico-alumina slags and alumina-lime slags against silicic acid-lime slags is determined. Under slags with much lime and alumina, iron has the greatest tendency to solidify in the unstable system with fine-eutectic arrangement of the graphite in the remaining melt. The silicic acid-lime slag does not change the formation of graphite because it is kept from the original iron. It can be concluded for practical purposes that it becomes feasible to obtain a desired structure by melting under a certain slag. The possible explanation of the cause of the differences is suggested and the various influences of the addition of Al and Zn are illustrated by means of tables and micrographs. Ha(5a)

Structure of a Used Shear Blade. (Gefüges eines gebrauchten Blockschermessen.) F. FETTWEIS. *Stahl und Eisen*, Vol. 51, Apr. 23, 1931, pages 528–529.

The examination of the shear blade shows the ferrite in a peculiar pine-tree arrangement. GN(5a)

Structure & X-Ray Analysis (5b)

Emission of Electrons from Metals. KARL T. COMPTON. *Journal of the Western Society of Engineers*, Vol. 36, June 1931, pages 137–148.

Actually there are five ways known whereby electrons can be caused to escape from metals. One of these is by raising the metal to a high temperature. This is usually known as thermionic emission. The second is by illuminating the metal by some suitable form of radiation, such as light or X-rays, which is known as the photo-electric effect. The third is by bombarding the metal with something moving with sufficiently high speed. The only things which can move with sufficiently high speed are electrons or ionized atoms or molecules, because they are electrically charged and can be given a high speed by passing them through a high voltage. The fourth method is by the contact of some one of these excited atoms or molecules with the metal; that is, a molecule which has inside of it an abnormally large amount of energy, only temporarily, to be sure. If, while in that state, it comes in contact with the metal, that energy may be delivered to the metal and result in the expulsion of one or more electrons. And the fifth way by pulling the electrons out of the metal by sufficient force. The only force that can pull an electron out of the metal is an electric force. That means applying a high voltage to the metal, sufficiently high so that the electrons are pulled out. The author discusses each method in some detail. WAT(5b)

An X-Ray Study of the Alloys of Silver with Bismuth, Antimony and Arsenic. Part I. S. J. BRODERICK & W. F. EHRET. *Journal of Physical Chemistry*, Vol. 35, Sept. 1931, pages 2627–2636.

An article accompanied by 3 diagrams and 2 sets of powder photograms, one of the system Ag–Bi and the other of the system Ag–b. Experimental methods are discussed and the conclusion is reached that the equilibrium diagrams which have been published for these systems by G. I. Petrenko are supported by the author's work. The maximum solubility of Bi in Ag is stated to be about 5.5%; that of Sb in Ag, 6%. OWE(5b)

X-Ray Analysis in Foundry Practice. (Roentgentechnik in der Giesserei.) R. BERTHOLD. *Die Giesserei mit Giesserei-Zeitung*, Vol. 26, Nov. 15, 1929, pages 632–634; Dec. 1, 1929, pages 666–672.

The use and advantages of X-ray inspection of castings and its value, economically, are explained. Beside the usual cast iron or cast steel, the light metals are also treated. Ha(5b)

The Reasons Responsible for the Widening of X-Ray Lines Obtained by the Debeye-Scherrer-Hull Method and by the Bragg Method. (Die Ursache der Lienienverbreiterung bei Pulver- und Drehkristallaufnahmen mit Röntgenstrahlen.) U. DEHLINGER. *Zeitschrift für Metallkunde*, Vol. 23, May 1931, pages 147–149.

The author describes the broadening lines of X-ray photograms to the following 3 sources: (a) small deviations in the space lattice constants due to concentration differences in solid solutions on the one hand and elastic distortions on the other hand; (b) abnormal small grain size as encountered in metals deposited by sublimation or electrolysis in metals colloidally dispersed and probably in some eutectoids, as, for instance, in pearlite and in martensite; (c) "quick fluctuations" in the lattice, that is to say, by inhomogeneous lattice distortions caused by the inhomogeneous distribution of a mixed crystal's component or as a result of elastic internal stresses. In conclusion, the author critically discusses the influence of rolling upon the broadening of X-ray spectrogram lines which phenomenon he ascribes to an inhomogeneous distortion or "bending" of the individual crystals created during the process of rolling. EF(5b)

On the Molecular Sphere of Activity of Metals and Some Conclusions Concerning Cohesive Forces. C. BENEDICKS. *Reprint, Arkiv for Mathematik, Astronomi och Fysik*, Vol. 22 A, No. 24, 1931, 13 pages. (In English.)

Methods of mathematical physics are applied to the problem of cohesive forces between molecules of metals. The radius of the molecular sphere of activity is taken as equal to twice the surface tension divided by the internal pressure. Calculating this for 13 metals, the order of magnitude of the radius agrees fairly well with the apparent atomic radius deduced from X-ray evidence. Poor agreement in some cases is ascribed to the use of surface tension data for the liquid state, while the data for internal pressure are for the solid state. The radius of molecular activity and the apparent atomic radius are both periodic functions of the atomic number. Bodies like Na with large atomic distances are soft, while those with small atomic distances are hard and brittle. If the atomic distance decreases successively, as on cooling of a metal, there will come a position beyond which further decrease of atomic distance will result in no increase in hardness. With thermal agitation nearly vanishing, the atoms may agglomerate into larger units. This may account for super-conductivity. HWG(5b)

Inspection of Welds with Gamma Rays. GILBERT E. DOAN (Lehigh University). *American Society for Steel Treating, Preprint* No. 34, 1931, 8 pages.

Paper to be read and discussed before the Boston Convention of the Society in Sept. 1931. The author reports results of examination of welds by the use of γ radiation. WLC(5b)

Electron Diffraction from Oxygen-Covered Tungsten. (Ueber Elektronenbeugung an sauerstoffbedecktem Wolfram.) W. BOAS & E. RUPP. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 18, 1931, pages 45–51; *Annalen der Physik*, Vol. 5, No. 7, 1930, page 983.

Tungsten was heated to 1800°, 2500° and 3000° C. in vacuum and the electron diffraction maxima determined for various angles of incidence and at various temperatures. Then it was treated with O at 400° C., the maxima determined and the oxygen-coated material then heated to various higher temperatures and the maxima determined at these temperatures. The results indicate that the surface layer on the oxygen-treated tungsten conforms to Langmuir's criteria for a monatomic layer of oxygen. In this case, and in the case of the surface of passive Fe, an O layer appears to be present, the same mode of combination of gas and metal atoms occurring in both cases. The experiments alone do not allow an explanation on the basis of simple saturation of the valence of the metal atoms by the gas atoms. The observed lattice spacing might be due to several layers of gas atoms or to a regular solution of oxygen in tungsten. HWG(5b)

X-Rays Suitable for the Determination of Small Changes in the Lattice Constant of Alpha Iron. (Eine zur Bestimmung von kleinen Aenderungen in der Gitterkonstante des α-Eisens geeignete Röntgenstrahlung.) A. E. VAN ARKEL & W. G. BURGERS. *Zeitschrift für Metallkunde*, Vol. 23, May 1931, pages 149–151.

The $K\alpha$ lines from Co are especially suited for the production of high quality diffraction photograms of Fe at ordinary temperatures from which the lattice constant, a_0, can be determined with great accuracy. If the adsorption limit of the radiated metal lies between the wavelengths of the $K\alpha$ and $K\beta$ lines of the anode, the β line will be selectively absorbed and will not appear, confusing the photogram. The application of this principle, using a camera with a high grazing angle, permits the determination of very small changes in the lattice constant of α Fe. Representative values of a_0, corrected to $\theta = 90°$, from different types of iron are given; Fe prepared from oxide by reduction with H, $a_0 = 2.8614$; electrolytic Fe, $a_0 = 2.8614$; first steel, $a_0 = 2.8623$; second steel, $a_0 = 2.8686$; roller-bearing steel with 1% Cr, $a_0 = 2.8635$; die steel with 12% Cr, $a_0 = 2.8666$; chromium iron with 25% Cr, $a_0 = 2.8675$. No change could be detected with adsorbed H, which must therefore be less than 0.02%. This method may also be used to determine internal stresses by the method of Sachs and Weerts (*Zeitschrift für Physik*, Vol. 60, 1930, page 481). RFM(5b)

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Watching Stresses at Work. HENDLEY N. BLACKMON. *Machinery*, June 1931, page 737.

The author discusses the use of the "photo-elastic" apparatus, which shows, by different colors on a screen, the magnitude and location of stresses in models of the parts being investigated. The models are made from transparent materials. Loads are applied to the models in the same manner as in actual service. Since stress distribution does not depend upon the material, as long as the elastic limit is not exceeded, results obtained with the models apply directly to steel and other materials. This photo-elastic apparatus thus provides a practical method of studying stresses in both simple and complicated parts, either stationary or moving, and it is hoped will solve the difficulty in determining the strength of machine members or other structures that are of such design that a satisfactory calculation cannot be made by the use of mathematical formulas. (6)

Anisotropy in Magnetic Materials. (Anisotropie in magnetischen Werkstoffen.) O. DAHL & J. PFAFFENBERGER. *Zeitschrift für Physik*, Vol. 71, No. 1–2, 1931, pages 93–105.

Based on the observation that the regularly crystallizing metals and alloys are isotropic for the physical properties, a method was developed to determine deformation and recrystallization textures by the magnetic anisotropy of regularly crystallizing metals. The tests were made on strips of Fe, Ni and an Fe-Ni alloy. The possibilities of this method for a practical determination of stresses are discussed. Ha(6)

The Stresses in Rotating Discs. A. F. CORNOCK. *World Power*, Vol. 16, Aug. 1931, pages 94–98.

The ordinary theory of stresses in rotating discs involves certain arbitrary assumptions as to the stress-strain relationships. A new theory is here developed, based directly on the theory of elasticity without recourse to these arbitrary assumptions, and the theory is worked out for hyperbolic and conical discs. It appears that the hoop tensions in hyperbolic discs, as calculated on the new theory, are generally larger than the hoop tensions calculated on the old theory, while the radial tensions are smaller. The method employed should be applicable to a wider range of problems. The article is almost entirely mathematical. WAT(6)

Deformation of Metals, with Special Reference to the Tensile Test. C. H. DESCH. *Transactions Institution of Engineers and Shipbuilders in Scotland*, Vol. 72, *Yearbook* 1929, pages 348–385.

The tensile test is a working test of the quality of metals but does not give the true elastic limit. The author prefers the proof load. Severely deformed metal has a lower density than the unstrained. Reduction of area at the point of failure is more closely related to the working properties of metals than is elongation. Viscous flow is a function of temperature and increases with time under constant load. The capacity of metals to be hardened by cold work can be inferred from the slope of the respective curves where the reduction of area of the cross section forms the abscissa and load in thousand pounds the ordinate. WHB(6)

Development of Casings for Deep Wells. F. W. BREMMER. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 355; abstracted in *Heat Treating & Forging*, Vol. 16, Oct. 1930, pages 1292–1294.

Paper presented at the Sept. 1930 meeting American Institute Mining Engineers, in Chicago. See *Metals & Alloys*, Vol. 1, Dec. 1930, page 908. Ha(6)

Actual Relation between Sheet Metal Thickness and Erichsen Impression. KARL DAEVES. *Metal Stampings*, Vol. 4, Apr. 1931, pages 306, 312.

Abstract of an article translated from *Stahl und Eisen*. See *Metals & Alloys*, Vol. 2, Mar. 1931, page 66. JN(6)

Mechanical Testing. Vol. I. Testing of Materials of Construction. R. G. BATSON & J. H. HYDE. E. P. Dutton, New York, 1931. Cloth, 6 × 8½ inches, 465 pages. Price $6.50.

This is a second and enlarged edition of the well-known work by 2 members of the Engineering Department of the National Physical Laboratory, England.

It is evidently written with the main idea of describing the apparatus used in testing materials for conformity to specifications. The catalog method of description is used, particular makes of testing machines being described and the parts being pointed out in such fashion as this. "The movement of the lever (C) is produced by a connecting rod (D) actuated by a variable eccentric (E) which is on the main shaft driven by the motor (F)." The authors even give the street and number of a firm from which a silica tube was obtained, on which a heating coil for a set-up for high temperature testing used by the authors was wound. This sort of thing keeps the authors from seeing the woods for the trees. While one may get from the context and by indirection, ideas as to the importance of axial loading in a tensile test, and side comments are made on it and many self-aligning grips are pictured, yet the authors do not bear down on its importance as much as it deserves.

The preface to the second edition states that rapid advances have been made since the publication of the first edition, in fatigue testing, hardness testing, and the testing of materials at high temperatures. These sections having been specially rewritten, one would expect a clear appraisal of the applicability of the test methods described. Calorimetric methods for rapid determination of endurance limit are described and the statement made that results are in good agreement with those found by other methods, although this is by no means a general truth and the authors probably know it. Certainly some of their N. P. L. colleagues know it. The authors do, however, recognize that in high temperature creep testing, it is doubtful whether short time flow tests can give accurate results. Such comments are, however, relatively rare, the authors being content to list a lot of mechanical devices with little attention to their relative accuracy and utility. Some critical appraisal of equipment and methods is, of course, included and a small amount of metallurgical data comes in to illustrate a point, but those features are subordinate to a description of the tools used. In the description of wear testing equipment there is lacking any discussion of what the results mean when one gets them.

It is dangerous to use the catalog method, for it can never be complete and each reader will note omissions of devices he would consider important enough to mention in such a catalog. The reviewer would have expected descriptions of the Tuckerman optical strain gage, the Templin grips for tension testing and the R. R. Moore fatigue machine. Any reviewer in any other country will note omissions of apparatus he would expect to see.

The book has value, as it does include description of, and reference to publications on, many modern testing methods and devices not included in the first edition. However, it lacks the "fundamentalism" of most books by N. P. L. authors, not being in the same class with the books on Fatigue of Metals by Gough and Creep of Metals by Tapsell. It should have been entitled "Apparatus for Mechanical Testing" rather than "Mechanical Testing." The N. P. L. staff certainly could write a fine book on the principles and objects of mechanical testing, on the proper types of apparatus to use to get results of desired accuracy and on how to interpret the test results. Doubtless the present authors could do so, but they have not. It is to be hoped that a third edition will feature principles instead of just cataloging tools. HWG(6)

Modern Material Testing Machines. (**Moderne Materialprüfmaschinen.**) O. Böttger. *Metallwirtschaft*, Vol. 10, Sept. 11, 1931, pages 720–723.

Various types of testing machines are described. Tensile testing machines are driven mechanically through screws or hydraulically with pumps. To measure the load on the test piece, balancing scales or pressure gages are used. Universal testing machines are a combination of tensile compression and bending test machines. The principal construction features of various types are described, also torsion, impact, Brinell and Rockwell hardness machines, Erichsen tester for deep drawing sheet material and endurance testing machines producing alternating tensile, compression, bending or torsional stresses. CEM(6)

The Graphical Evaluation of the Bending Test. (**Die zeichnerische Auswertung des Biegeversuchs.**) R. Mitsche. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Mar. 20, 1931, pages 246–247.

A generally applicable method is developed to determine graphically the bending strength of cast iron. A numerical example illustrates the method. Ha(6)

Automotive Engine Piston Tests. (**Werkstoffprüfung für Kolben von Fahrzeugmotoren.**) Ernest Mahle. *Maschinenbau*, Vol. 10, May 21, 1931, pages 345–350.

A complete description of the methods and equipment used in the testing of pistons as to temperature, expansion, conductivity, hardness, strength in compression, change in shape, effect of piston pins, etc. WHB(6)

The Status of the Impact-Notch Test in Germany. (**Der Stand der Kerbschlagprobenfrage in Deutschland.**) M. Moser. *Krupp'sche Monatshefte*, Vol. 12, Aug.–Sept. 1931, pages 223–229.

The following questions are discussed: What advantages does the notch-impact test offer which other mechanical tests do not possess and what possibilities does it have from the point of view of measuring technique? Is this test more suitable for standardization than any other? From the results of tests to clarify the situation, a new arrangement of the specimen for the notch-impact test has been developed. This arrangement promises well for general acceptance because it gives reliable, reproducible results. Ha(6)

On the Yield-Point of Mild Steel. Fujio Nakanishi. *Report* No. 72, *Aeronautical Research Institute*, Tokyo Imperial University, June 1931, 140 pages.

Various theories concerning the elastic limit have been advanced, but none of them can account for the yielding of mild steel. The object of this paper is to propose a new theory. The author considers that the yielding of material is a problem of stability, analogous to the critical point of viscous flow through a pipe. The material will yield when the state of stress becomes unstable; all the stress distribution in the body must therefore have effect on the yield-point. (6)

The Work-Hardening Capacity and Elongation Properties of Copper. Hugh O'Neill & J. W. Cuthbertson. *Institute of Metals, Advance Copy* No. 580, Sept. 1931, 17 pages.

The various methods for determining work-hardening capacity are discussed. Cupping tests are frequently used with sheet materials, but other forms of tests are needed for testing material in other forms. Data obtained by several different kinds of tests on Cu are given. The Tetmajer "uniform elongation" and the Bertella-Oliver "extensibility" were found to be accurate measurements of the workability. Meyer "n" values were erratic. The Herbert pendulum results did not agree with results obtained by other methods. 16 references. JLG(6)

Note on the Diameter Measurement of Certain Brinell Indentations in Cold-Rolled Metal. Hugh O'Neill. *Institute of Metals, Advance Copy* No. 579, Sept. 1931, 4 pages.

The readings of the diameters of Brinell impressions in hard rolled metals may vary by as much as 4% due to the shape of the lip of the impression. The smallest diameter observed is the true diameter. "Dark-ground" illumination always gave the true diameter. 1 reference. JLG(6)

On the Investigation of the Asymmetry and Flaws in Samples of Ferromagnetic Material. (**Sur la recherche de la dissymétrie et les défauts dans les pièces ferromagnétiques.**) Jean Peletier. *Comptes Rendus*, Vol. 193, Sept. 7, 1931, pages 420–421.

An article, accompanied by one diagram, in which a description is given of a method employed for the investigation of ferromagnetic materials by magnetic means. OWE(6)

On the Elastic Extension of Metal Wires under Longitudinal Stress. L. C. Tyte. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Vol. 10, Dec. 1930, pages 1043–1052.

The measurement of the elastic elongation of metals, especially for proving Hooke's law, can be carried out in an apparatus in which the changes of lengths of 2 wires are compared. This may be applied if the wires have the same section but different lengths and loads. If the length of one wire is half the length of the other but the load is twice that of the other, the elongation must be the same according to Hooke's law. The differences are made visible by an optical device. Details of the apparatus are described. Ha(6)

Strengthening by Reversals of Stress. (**Verfestigung durch Wechselbeanspruchung.**) W. Schwinning & E. Strobel. *Zeitschrift für Metallkunde*, Vol. 22, Nov. 1930, pages 378–381; Dec. 1930, pages 402–404.

Steel with 0.05% C and brass with 72% Cu were studied by subjecting wires of these materials to reversals of stress (bending) and then determining the ultimate tensile strength, the yield point and the elastic limit. Data collected are given graphically. More data and conclusions will be given in a concluding article. The second part of the article gives an account of the changes in structure (slip lines, grain boundaries, etc.) and the effect of heating (recrystallization) upon the structural changes observed. A Study of Welded Metals under Fatigue Tests. G. E. THORNTON. *Engineering Experiment Station Bulletin* No. 34, *State College of Washington*, 1930, 31 pages; *Journal American Welding Society*, Vol. 9, Oct. 1930, pages 48–66.

The object of the tests undertaken in the study herein reported was to compare the different types of welds in which a flexure of the specimen occurs when subjected to a continuous series of stress reversals. Such a condition is present in a member under continuous or spasmodic vibration. The tests were undertaken by the Engineering Experiment Station of the State College of Washington in coöperation with the mechanical engineering department of the same institution and with the American Welding Society. The field covered in this work consists of tests of oxy-acetylene welds, resistance welds and flash welds, and some work on atomic hydrogen and metallic arc-welds. In determining a policy of securing specimens, it was decided to test small specimens in fatigue and to obtain a true cross-section of the welding field by soliciting welded coupons from companies doing different types of welding. The average of these tests gives a lower result than would be obtained if one experienced man were doing all the welding with the knowledge that his welds were to be tested for data. The author believes that this cross-section of the entire field is a much better indication of what to expect from welds than the results obtained by any one individual. The author indicates that the study will be continued with tests on the different types of shielded metallic arc-welds and on specimens of all types of welds which have been uniformly heat-treated. The Fatigue Fracture. (**Ueber den Ermüdungsriss.**) N. DAWIDENKOW & E. SCHEWANDIN. *Metallwirtschaft*, Vol. 10, Sept. 11, 1931, pages 710–714.

5 references. Tests were made to determine the effect of fatigue cracks on the tensile strength of the remaining portion of the metal. 0.15–0.20 C steel annealed at 900° C. was subjected, in a Wöhler rotating beam machine, to loads exceeding the endurance limit for various numbers of cycles. The partly cracked test pieces were then pulled in a tensile machine. In order to obtain a brittle break the tensile tests were made in liquid air. When the breaking load in kg. is plotted against the number of cycles, the curve first gradually slopes downward and at 300,000 cycles bends sharply downward. This point corresponds to the beginning of the crack. Plotted against the area of the fatigue crack, the breaking load in kg. drops very sharply in the first mm.² from 940 to 540 kg., then bends and proceeds in a sloping straight line. This shows how great the notch effect is. If the fatigue crack is polished out after it first appears, the break in the first curve is changed from 300,000 to 1,000,000 cycles. X-ray examination of the outer and intermediate zones and the unbroken core showed no difference in crystallographic orientation. A fatigue crack starts by a number of small cracks forming at not exactly the same cross section which increase in width and depth until they meet, producing the outer zone with rough surface. From then on the single crack proceeds with a smooth surface forming the intermediate zone. CEM(6f)

A Few Observations of Fatigue Tests. (**Einige Beobachtungen bei Dauerstandversuchen.**) R. MAILÄNDER. *Krupp'sche Monatshefte*, Vol. 12, Aug.–Sept. 1931, pages 242–243.

The conception of the term "fatigue test" or "static endurance test" is discussed and illustrated by an example. The definition of this term is not yet absolutely certain. The tests made were only to give a basis for further practical research. Ha(6f)

Endurance Tests of Steel Wires with Alternating Tension Loads. (**Dauerprüfungen unter wechselnden Zugbeanspruchungen an Stahldrähten.**) A. POMP & C. A. DUCKWITZ. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 13, No. 5, 1931, Report No. 175, pages 79–91; *Stahl und Eisen*, Vol. 51, May 14, 1931, pages 620–622.

The experiments were made on 4 steels:

C	0.43%	0.62%	0.62%	0.83%
Si	0.17%	0.20%	0.21%	0.22%
Mn	0.41%	0.40%	0.42%	0.45%

The wires were patented and drawn as follows:

Steel	Furnace Temperature	Load Temperature
A	1000° C.	550° C.
B	1000° C.	550° C.
C-Group I.	900° C.	550° C.
C-Group II.	1000° C.	450° C.
D	1000° C.	550° C.

Diameter of wire at patenting—mm.	Number of drafts after patenting	Diameter of wire after drawing-mm.	Reduction of area %
1.2	2	0.9	44
1.6	4	0.9	68
2.1	6	0.9	82
2.9	8	0.9	90

At first the normal physical tests were made with all wires. The curves of tensile strength show the normal course of increased tensile strength with increased reduction of area and increased C content in the same groups of drafts. The number of kinds decreases with reduction of area and C content. The number of twists generally increases with the number of drafts. A special machine was developed for the alternating load endurance tests, in order to determine the initial strength. With the wires A and B, the initial strength decreases with the number of dratfs, but with wire C, Group I, and wire D, the initial strength increases first at the reductions of 44 and 68% and then decreases. In wire C, Group II, the initial strength increases up to 82% reduction. The ratios between initial strength and tensile strengths were established. Steel A has the highest ratio; steel D, the lowest one. The ratio decreases with the number of drafts but more rapidly with the low C steel than with the higher C steel. A definite relation between initial strength and tensile strength does not exist. In case a high initial strength is desired, only small reductions should be used after patenting. GN(6f)

On Fatigue Strength. (**Beitrag zur Frage der Schwingungsfestigkeit.**) W. SCHNEIDER. *Stahl und Eisen*, Vol. 51 Mar. 5, 1931, pages 285–292.

After discussing the importance of the various physical properties to the designer, the present state of knowledge on the oscillation strength is discussed. The results of investigations of the effect of the surface condition upon the oscillation strength is surveyed. An increase of the load is permissible under the application of a certain static pre-load even if notches or rivet holes are present in high quality steels. GN(6f)

Endurance Tests on Patented and Drawn Wire. (**Några utmattingsförsök med patenterad och dragen ståltråd.**) ANTON POMP, CARL DUCKWITZ & ALFRED LINDEBERG. *Jernkontorets Annaler*, Vol. 115, Aug. 1931, pages 371–403.

Wires with C contents from 0.43 to 0.83% and reduced by drawing from 44 to 90% were subjected to endurance tests with varying tension in a machine and the results were compared with tensile, bending and torsion tests. The best endurance was found in wires with low C content subjected to intermediate reduction by drawing. A good correlation was found between the bending tests and the fatigue tests, while the tensile and torsion tests gave no indication of the endurance of the wires. Endurance tests with varying tension were also performed on ropes of 42 wires. When normal heat-treating was employed (temperature of furnace 1000° C., temperature of lead-bath 550° C.), the best endurance was shown by ropes made from wire with a low C content (0.43%) and drawn 6 to 8 passes (reduction 80–90%). By modifying the heat-treatment good results are also obtained with higher contents of C. No pronounced connection was found between the different wire-tests and the endurance tests on ropes. In certain circumstances, the torsion test gives an indication if a wire is suitable for rope. The endurance machine for wire seems especially promising for the testing of spring wire. HCD(6f)

Sheaths on Underground Power Cables. D. W. ROPER. *Bulletin, Utilities Research Commission*, Vol. 2, Oct. 1931, pages 2 and 3.

Failures in oil-filled cable sheaths are discussed. Lead cable sheaths used in the telephone industry have been improved by alloying, as with Sb; the improvement is in line with the indications of laboratory endurance tests. In the use of power cable, the problem is not primarily one of small vibrations, but of relatively slow bending of large amplitude. In full scale tests in a dummy manhole, sheaths of lead alloyed with Sb, Sn or Ca have not been found superior to commercially pure Pb, so the results of laboratory tests of the type made by the telephone companies are not yet to be taken as accurate indications of serviceability for power cable sheaths. Since stress of 200 lbs./in.² or higher occur in service, the creep properties of lead sheaths are important. HWG(6f)

Notch and Corrosion Endurance Strength. (**Kerb- und Korrosionsdauerfestigkeit.**) P. LUDWIK. *Metallwirtschaft*, Vol. 10, Sept. 11, 1931, pages 705–710.

Contains 6 references. Physical tests including, besides the regular tensile and hardness tests, endurance tests with polished and notched specimens, and specimens subjected to corrosive liquids were made on 48 metals, non-ferrous, cast iron, carbon and alloy steels. The notches were 0.1–0.4 mm. deep, 60°, with a 0.05 mm. radius at the base. Other test bars had a collar with a diameter and width twice the diameter of the test piece, and fillet of 0–0.5 mm. The endurance limit of duralumin, brass, rolled bronze, cast iron and austenitic steel was hardly affected by the notch, calculated on the reduced cross section, but that of hardened steels was reduced considerably. In Cr-Ni steel an increase in the depth of the notch produced a greater lowering. In specimens with collars, the endurance limit was lowered below that of the notched test bars, especially if the fillet was small. A Cr-Ni steel of 108 kg./mm.² tensile strength had an endurance limit with polished test bar of 54 kg./mm.² and with a collar without fillet of only 22 kg./mm.². The comparatively small influence of notches on the endurance limit of cast metals is due to internal porosity which acts as notches and causes a low endurance limit even in polished test bars. The notched endurance limit, rather than the lowering due to notches, is of importance in evaluating the properties of metals. The ratio of endurance limit in torsion to the endurance limit in bending of rolled and forged metals was 0.575 regardless of the heat treatment. The effect of notches on torsional and bending endurance limits was in the same proportion. In cast metals the ratio was much higher. The corrosion endurance tests were made with tap water, natural and synthetic seawater in the presence of air. It was found that the usual 10,000,000 reversals were not enough under these conditions and that the results were indefinite. The corrosion endurance limit of most of the metals examined was extremely low. For instance, the highest results for light metals was 7 kg./mm.² and for steel, 14 kg./mm.². α brass gave better results. In stainless V2A steel, the effect of seawater cut the endurance limit in half, although the surface was not attacked. Heat treatment hardly increases the corrosion endurance limit over that of the annealed metals and, therefore, the drop is greatest in hardened steels. A Cr-Ni-W steel of 162 kg./mm.² tensile strength had a corrosion endurance limit of only 12 kg./mm.². In corrosion endurance tests the fracture of pure Al and soft steel was usually intragranular. Endurance of Steel Depends on Structure, Strength and Ductility. Correspondence from EINAR ÖHMAN, Stockholm, Sweden. *Metal Progress*, Vol. 20, Sept. 1931, page 88.

The writer reports results of A. Lundgren on relation between fatigue and ultimate strength as affected by change in heat treatment and the ductility as measured by reduction in area in a tensile test. WLC(6f)

Increase of Endurance Limit of Bolt-Threads by Cold-Working the Surface. (**Die Steigerung der Schwingungsfestigkeit von Gewinden durch Oberflächendrücken.**) H. ISEMER. *Mitteilungen des Wöhler-Instituts*, No. 8, 1931, 64 pages, 12 references, 21 figures. Published by N. E. M. Verlag, Berlin. Price 4 R.M.; *Metallwirtschaft*, Vol. 10, Sept. 11, 1931, pages 714–717.

Two hardened steel rollers, shaped to fit into the groove at the base of the threads of a threaded test bar were mounted in a frame and backed up by calibrated springs. By mounting the frame on the bed of a lathe and running the rollers back and forth, usually 15 times, the groove was work hardened. It was necessary that the thread be accurately cut in order that the rollers make proper contact. The pressure required for the best degree of work hardening varies for different materials. No record was made of the increased surface hardness produced, the hardening being expressed only in terms of pressure on the rollers.

Using a rotating beam specimen so loaded that the maximum stress came on the work-hardened, threaded section, and leaving some threads unworked at the location of lower stresses, the bar was loaded and run to fracture. From the location of the break the stress at that point was calculated and comparison made between the stress necessary to break the bar from fatigue at worked and at un-worked threads.

Medium carbon steels gave about 20–25% increase due to cold-working of the threads at suitable pressures. A steel of 0.93% C, worked by only three passages of the rollers, showed very little improvement, but this may be due to imperfect threads. A steel of 0.30% C, 0.95% Cr, 4.2% Ni, 800–850° C oil, 620° C. draw showed some 45 to 65% increase after working with rather high pressure on the rollers, depending on the pressure used. Lautal improved some 30%. A 58% Cu, 2½% Pb brass showed some 15 to 20% improvement.

No simple relation appears between the damping ability of the materials and the improvement obtained by work-hardening the threads. On damping test, two bars of the same type of steel, not checked for analysis and mechanical properties, showed entirely different types of curves.

Electroplating (7a)

The Definition and Determination of "Free Cyanide" in Electroplating Solutions. W. Blum. *Preprint, Transactions Electrochemical Society*, Vol. 60, Sept. 1931, pages 21–26.
A definition is proposed for the American Standards Association: "The free cyanide in a electroplating solution is the excess of alkali cyanide above the minimum required to give a clear solution." A volumetric method is also proposed to determine this "free cyanide" by a titration against a standard solution made of a salt of the same metal as is to be deposited from the bath. LCP(7a)

Distribution of Crystals of Chromium Electrodeposited in Thin Plates. D. T. Ewing, H. E. Publow & C. D. Tuttle. *Michigan Engineering Experiment Station, Bulletin* No. 33, 1930, 20 pages.
The Bulletin contains 33 photo-micrographs of the steels used as basis metals, and of the deposits obtained. The investigation was undertaken for the purpose of studying the nature of the formation of crystals of metals which are deposited electrolytically. The work is limited to the formation of crystals during the initial stages of deposition in order to note the effect of the composition and the physical condition of the basis metal upon the nature of the deposit. The work was further limited to the composition of the plating solution, current density and certain other factors, but the temperature and time were varied. The experimental work includes the study of the crystal growth of Cr deposited upon carefully polished surfaces of steels with C contents of 0.20, 0.85, 1.20 and 1.50% and on Armco Iron. The time of plating varied from 15 seconds to 8 hours and temperatures of 45° and 55° were used. The Cr plating solution contained 250 g. CrO_3 and 2 g. $BaSO_4$/liter. The initial Cr deposits were not microscopically uniform; invariably the Cr deposited first upon the cementite and spread rapidly to the ferrite within the pearlite areas. This effect was noted in the samples of low C content as well as in those where cementite was concentrated within the crystal boundaries. Cu and Ni were found not to deposit selectively but evenly over the surface of the steels, and Cr deposited over Cu and Ni was uniformly deposited over the metal surface. The color of the deposits changed during the first stages of deposition; up to 15 seconds the deposits were dull, after which they became brighter. At the higher temperature (55°) the changes noted above were accelerated and the basis metal was more uniformly covered in shorter time. The higher temperature also decreased the tendency for Cr to deposit selectively. Short cracks were found to form after the first few minutes of deposition. No correlation was found between the cracks and the crystal boundaries of the basis metal. (7a)

The Progress of Chrome-Plating during the Last Years. (Die Entwicklung der Verchromung in den letzten Jahren.) W. Birett. *Werkstattstechnik*, Vol. 25, Mar. 1, 1931, pages 135–140.
While no principal change in the technique of chrome plating is noted, several important details have been studied more thoroughly and the limitations for the application of the method more exactly circumscribed. It has been recognized that only solutions of the type of chromic acid in sulphuric acid are suitable for plating and that supervision should be the permanent task of a works laboratory. Chrome plating alone is not a protection against corrosion as the deposit is too porous on account of the development of hydrogen. Nickel plating as an intermediary layer on which chrome is deposited is, at present, the recognized method for obtaining a protection against corrosion. The question of safety of chrome deposits against chemical action is not yet sufficiently solved. In any case, experience has shown that well polished surfaces before plating guarantee a much greater protection against attack. A field where chrome plating has proved of great value is the plating of wood-working tools, especially millers (which showed a much longer life and needed less regrinding). This is done only at the front and not on the cutting edges. The accumulation of chromic acid in the vapors above the baths which are usually condensed on iron grates has proved to be very costly. On the other hand, the prevention of the vapor by covering the bath with protective films of oils is applicable only when simple objects of straight lines are to be plated as otherwise the oil might stick to holes, protrusions, etc., and prevent the deposition of metal. Particular care should be given to the exhaustion of the explosive oxy-hydrogen gas which should be exhausted with 300–500 times its amount of air to prevent self-ignition. Ha(7a)

The Porosity of Electroplated Chromium Coatings. W. Blum, W. P. Barrows & A. Brenner. *Bureau of Standards Journal of Research*, Vol. 7, Oct. 1931, pages 697–711.
Various methods for detecting porosity of Cr coatings were found to yield consistent results. Very thin deposits contain round pores. As the thickness is increased the porosity decreases to a minimum, after which an increase in thickness is usually accompanied by the formation of cracks, either parallel or random. The well-known Cu deposition method for detecting the porosity depends upon the fact that Cu will deposit only in pores or cracks and not on the Cr. This test was made semiquantitative by measuring either the average apparent current density, or the weight of Cu deposited in 2 minutes at 0.2 v. The following conclusions are based on such measurements. Their practical significance will be determined by exposure tests now in progress. The porosity usually increases on standing. This increase is accelerated by heating to 200° C. Changes in the composition of the solution have no marked effect on the porosity. An increase in the temperature of deposition, for example to 65° C., instead of the usual temperature of 45° C., greatly decreases the porosity, especially of thick coatings. At any given temperature, the porosity is increased by raising the current density. Deposits on Ni are less porous than those on other base metals. This difference is at least partly due to the greater ease of securing a bright finish on Ni prior to the Cr plating. WAT(7a)

The Application of Electrodeposited Metals to Engineering. C. H. Faris. *Machinery*, London, Vol. 37, Feb. 28, 1931, pages 701–703.
Paper read before the Manchester Association of Engineers. Account of the Fescol electrodeposition process as applied to the building up of worn engineering parts. The outstanding characteristic of the process is the high degree of adhesion obtained between the basis metal and the electrodeposited plating. Some details are given of a report by the National Physical Laboratory on the adhesive or shear stress of Fescolized samples. The hardness of the deposited metal is regulated to conform to the conditions of wear for which the part is designed. Brief reference is also made to the applications of thinner nickel deposits for the plating of food utensils, steam parts and other articles working under corrosive conditions. Ha(7a)

The Electro Deposition of Silver from Argentocyanide Solutions. Part II. Samuel Glasstone & Edward B. Sanigar. *Transactions Faraday Society*, Vol. 27, July 1931, pages 309–312.
Reduction in polarization is accompanied with bright deposits obtained with the presence of potassium cyanate in stock Ag solution. Other brightening agents as carbon disulphide also lower polarisation. PRK(7a)

Gold and Silver Recovery from Tin Slime. John B. Kasey. *Engineering & Mining Journal*, Vol. 132, Sept. 14, 1931, pages 217–218.
The tin slime dealt with in this work originated from the electrolysis of scrap brass and bronze, containing small amounts of Ag and Au and larger amounts of Pb, Sn, Zn, Ni, iron oxides and admixed sand. The wet slime, which originated in a solution of H_2SO_4, consists of sulphates, basic sulphates, metallics and free acid. The problem in treating the slime is to separate and recover 4 different metals and alloys: an alloy of Au and Ag; pure Cu; a white-metal alloy of Sn, Pb, Sb and Ni or its salts. The recovery of Au and Ag are alone discussed. Cu in the slime is made the collector. Experimental work is outlined. WHB(7b)

The Rapid Determination of Current Efficiency in the Electrolysis of a Zinc Sulfate Electrolyte. F. E. Lee & A. H. W. Busby. *Preprint, Transactions Electrochemical Society*, Vol. 60, Sept. 1931, pages 1–7.
Cathode efficiency of zinc sulphate electrolyte from leaching of roasted blende is determined indirectly by measuring the H given off per ampere-hour at the cathode, thus, the cathode efficiency for Zn is equal to 100 minus cathode efficiency for H. This method checks closely with that based on the weight of zinc deposit, but it takes only 45 mins. as against several hours required by the latter method. LCP(7b)

Technical Applications of the Electrodeposition of Metals. H. J. T. Ellingham. *Journal Institute of Metals*, Vol. 47, Sept. 1931, pages 1–5.
The paper summarizes some of the main features of the various electrolytic metal deposition processes and indicates the general principles on which they are based and the scope of their application. 3 tables are given in each of which the metals are arranged in the electrochemical series, starting with the basest and ending with the noblest metal. The baser the metal, the more readily it is oxidized or attacked by dilute acids, but the less easily it is obtained in the free state by chemical reduction of its oxide or salts. The first table includes metals which react with water and cannot, therefore, be deposited from aqueous solutions; these are Li, Rb, K, Sr, Ba, Ca, Na, Mg, Be, Al, Ce, rare earth metals. The second table contains metals which can be deposited from aqueous solutions. Mn, Zn, W, Cr, Fe, Cd, In, Tl, Co, Ni, Sn, Pb, Sb, Bi, As, Cu, Ag, Hg, Pd, Pt, metals of the Pt group, Au belong in this table. The third table contains metals of variable or undefined electrochemical character, whose positions in the electrochemical series are not known. Most of them can, however, be electrodeposited from molten salt baths, e. g., Ti, Zr, Th, U. Very little is known about the possibility of electrodepositing V, Nb, Ta, Mo in this manner. The tables also give the solutions from which they can be extracted, in which they can be electrolytically refined and electrodeposited. 15 references. Ha(7b)

Cathodic Forms of Electrolytic Tin. (Ueber kathodische Abscheidungsformen des Zinns.) F. Foerster & H. Deckert. *Zeitschrift für Chemie*, Vol. 36, Nov. 11, 1930, pages 901–923.
Crude *m*-cresolsulphonic acid in the electrolysis of a H_2SO_4 solution of $SnSO_4$ can repress the tendency of the Sn to form needles growing perpendicular to the surface of the cathode, and to form the Sn precipitation in a smooth and even surface. The by-products formed in the sulphonation of *m*-cresol influence the separation of the Sn because they are absorbed by the precipitate. The amount and nature of the by-products depend on temperature and time of sulphonation. Above 120° C., colloidal by-products are also formed. When the concentration of impurities is low, the Sn deposit is needle-like to spongy. As the concentration increases, the deposit becomes granular or smooth and, when high, the crystals become fine and arranged in unordered patterns. Finally, the plated Sn becomes structureless and milk-white in color and a point is reached when colloidal material precipitates with the Sn. The absorption is less at high temperatures and greatest at low temperatures. Ha(7b)

Germanium in Relation to Electrolytic Zinc Production. U. C. Tainton & E. T. Clayton. *Metal Industry*, London, Vol. 37, Sept. 5, 1930, pages 229–230.

The Electro-Deposition of Copper in the Presence of Gelatin. Robert Taft & Harold E. Messmore. *Journal of Physical Chemistry*, Vol. 35, Sept. 1931, pages 2585–2618.
The authors have studied the effect of introducing increasing amounts of gelatin into solutions of copper sulphate upon the form of the cathode deposit. In these experiments the concentrations of gelatin and of copper sulphate, the current densities and the temperatures have been varied. The authors believe that the most direct explanation of the phenomena observed requires the assumption that the Cu deposited by the current adsorbs gelatin upon its surface. Measurements of the magnitude of the cathode polarization in the cell $Cu/CuSO_4$, Gelatin/Cu have been made. The results obtained are taken by the authors to indicate that complex cations are formed between cupric ion and gelatin but that the electro-chemical process occurring at the cathode is primarily discharge of cupric ion. OWE(7b)

METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

The Attack on Mild Steel in Hot-Galvanizing. Edward J. Daniels. *Institute of Metals, Advance Copy* No. 566, Sept. 1931, 17 pages; *Korrosion und Metallschutz*, Vol. 7, Oct. 1931, page 251.
The rate of attack of mild steel by molten Zn was determined by immersing steel samples in various grades of Zn and Zn alloys at various temperatures stripping the coating with a solution of H_2SO_4 plus As_2O_3, and determining the loss in weight. There was little difference in the loss of weight in high-grade and less pure Zn. Below 500° C. the loss in weight was proportional to the square root of the time, while above this temperature the loss was directly proportional to the time. Microscopic examination showed that below 500° C. a continuous coating of $FeZn_7$ protected the steel from subsequent attack, but that when this temperature was exceeded the layer of $FeZn_7$ was porous and furnished little protection. Small amounts of Al and Sb in the Zn slightly increased the rate of attack. The steel was rapidly dissolved in Zn-Cd alloys which was found to be due to the Cd preventing the formation of a continuous layer of $FeZn_7$. The tests were taken to indicate that a galvanizing pot should have a very long life if no part of the pot was heated to above 480° or 500° C. Examination of failed pots showed the presence of alloy layers similar to those observed in the samples. 9 references. EF+JLG(8)

Surface Protection by Means of the New Homogen-Pistol of Schoop. (Der Oberflächenschutz mittels der neuen Homogen-Pistols von Schoop.) Alf. Karsten. *Oberflächentechnik*, Vol. 7, Sept. 16, 1930, pages 173–175.
Fine metallic powder, as zinc, tin, nickel, also tungsten or silver, is driven by compressed carbonic acid from a tank to an oxy-acetylene flame. The pressure of 6–7 atmospheres imparts to the metal dust a velocity of about 25 ft./min. so that the body to be protected is covered with a very uniform layer of metal which adheres firmly. Not only metals but any other material can be metalized by this method. A few examples are illustrated. Ha(8)

Mottled Tinplates. J. C. Jones (University College, Swansea). *Iron & Steel Institute, Advance Copy* No. 11, Sept. 1931, 11 pages; *Iron & Coal Trades Review*, Vol. 123, Oct. 2, 1931, pages 487–489.
Mottled or dull tinplate only occurs when high Sn yields are sought. It was found that under some conditions mottling resulted in some steels and not in others. Macrostructures of bars from which the plates were produced indicated that the bars with the thickest skin were the least susceptible to mottling. Mottling is also dependent on conditions in the Sn pot, and was found to be produced by the flux rather than by the Sn. An NH_4Cl flux was found to give bright sheets when substituted for a $ZnCl_2$ flux that was producing mottled sheets. The NH_4Cl flux, however, would not remove grease as readily as the standard flux. It was concluded that the better action of NH_4Cl was due to a greater frothing rather than to a greater reactivity. Ha+JLG(8)

Investigations on the Occurrences during Zinc Coating. On the Solubility of Pure Iron in Molten Zinc. (Untersuchungen über die Vorgänge beim Verzinken. Ueber die Löslichkeit von reinem Eisen in geschmolzenem Zink.) H. Grubitsch. *Stahl und Eisen*, Vol. 51, Sept. 3, 1931, pages 1113–1116.
The solubility of Armco-iron in chemically pure Zn is very slight up to 470° C. and practically independent of the time. A maximum of solubility is observed at 515° C., but the solubility increases again at higher temperatures. The dependence of the solubility upon the time then rapidly decreases. GN(8)

Temperature and Purity of Zinc as Factors in the Production of Galvanizer's Dross. Wallace G. Imhoff. *Iron & Steel of Canada*, Vol. 14, June 1931, pages 93–94, 107.
Discussion of conditions under which galvanizer's dross is produced in plant operation, indicating the importance of the quality of the Zn used and the temperature of the bath. The results of experiments made to answer the question, "Can dross be made from pure Zn at any temperature?" are described. The article is accompanied by 3 photographs. The conclusions reached are that heat alone will not produce dross or Zn-Fe alloy in pure Zn, and that, when no Fe is present, even temperatures far above those used, or found in hot galvanizing, will not produce dross or Zn-Fe alloy crystals. OWE(8)

The Use of Tin in the Galvanizing Bath. Wallace G. Imhoff. *Heat Treating & Forging*, Vol. 17, July 1931, pages 675–678.
The addition of Sn to the galvanizing (Zn) bath has the tendency to cleanse the bath of oxides, scurf and dirt. The coating assumes the Sn spangle: a fern-like, large star-like crystal-forming growth. The amount of Sn added varies with the different kinds of work; large additions will almost close up the spangle and show a dull, solid coating. Sn as an addition to baths that contain an excess of Al is especially beneficial because Sn combines with Al, thus eliminating the oxide skimmings. An excess of Sn may produce a tarnish over the coating. Several bath compositions for various purposes and materials to be galvanized are given. Ha(8)

The Tinplate Industry. D. Griffiths. *Journal Society Chemical Industry*, Vol. 50, May 22, 1931, pages 431–437.
A brief review covering the history, metallurgy, manufacture and products of the tin plate industry. VVK(8)

The Protection of Metals by Metallic Films. Ernest S. Hedges. *Journal Society Chemical Industry*, Vol. 50, Sept. 18, 1931, pages 768–772.
2 kinds of protection may be afforded to iron by metallic films. When the protecting metal is less noble than the base metal such as in the zinc-coating of iron, the protection is partly electrochemical; the Zn, in the presence of an electrolyte becoming the anode and corroding, the Fe becoming the cathode and remaining unattacked. When the protecting metal is more noble than the base metal, as Fe coated with Cu, the protection afforded is mechanical like that offered by a coat of paint excluding the corrosive agencies and remaining effective only as long as they completely cover the surface. Protective metallic films must have: ability to undergo deformation without peeling, adherence to the base, resistance to abrasion, brightness and general appearance, and paint-holding properties. Protective metals can be applied by hot-dipping (Zn, Sn and Pb), electroplating (Zn, Cu, Ni, Cr etc.), metal spraying (Zn, Al), and cementation (sherardising, chromising and calorizing). All of these processes are discussed. VVK(8)

Alclad and the Aluminum Coating of Aluminum Alloys. (Le revètement des alliages d'aluminium et l'Alclad.) P. M. Haenni. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 575–585. 18 figures, 29 references.
The value of the Al coating of duralumin for protection against intercrystalline corrosion, the electrolytic protection afforded by the coating and the mechanical properties of Alclad are reviewed. No new information is included. HWG(8)

Effects of Cadmium Vapors. (Kadmiumdampf-Einwirkung.) L. Schwarz & W. Deckert. *Zentralblatt Gewerbehygiene und Unfallverhütung*, Vol. 18, No. 3, 1931, page 66.
Certain injurious effects which were experienced in spraying of Zn coatings are ascribed to low contents of Cd in the zinc (0.12% in the case described). Purer zinc dust or exhaustion of the vapors is recommended as the remedy. Ha(8)

INDUSTRIAL USES & APPLICATIONS (9)

Some Factors Influencing the Sizes of Crankshafts for Double Acting Diesel Engines. S. F. Dorey. *Northeast Coast Institution of Engineers and Shipbuilders Transactions*, Vol. 47, June-July 1931, pages 229–316.
The general procedure for determining the diameter of a shaft subjected to combined bending and torsion is to calculate the equivalent bending or twisting moment and to use a constant working stress irrespective of the type of engine. In the method put forward in this paper a different stress is allowed for each type of engine depending upon the ratio of twisting moment to bending moment and also on the fluctuations of shear stress at the most severely stressed crank. Thus the diameter of a crank-shaft subjected to large fluctuations of torque is ascertained by allowing a lower working stress than in the case of a shaft subjected to small fluctuations yet having the same maximum torque. The method indicated in the first part of the paper shows how the strength of the crankshafts can be ascertained from a knowledge of the fatigue properties of materials at various ranges of stress, and has been used to determine suitable diameters of crankshafts for double-acting Diesel engines, based on previous experience with steam reciprocating engines and single-acting Diesel engines. The results indicate that for engines having a small number of cylinders the working stress permissible should be appreciably less than for engines having a large number of cylinders for the same factory of safety. For two-stroke-cycle double-acting engines having a large number of cylinders the maximum working torsional stress due to combined twisting and bending suggested is somewhat in excess of that usually adopted in existing steam engines and single-acting Diesel engines, viz., 7000–7500 lbs./in.² as against 5600 lbs./in.² and as a result some comments have been made relative to the shrinkage grip for built shafts. Catalytic Reactions of Sulfur Compounds Present in Petroleum. I. High Sulfur Naphtha in Contact with Nickel and Iron Catalysts. J. C. Elgin, G. H. Wilder & H. S. Taylor. *Industrial & Engineering Chemistry*, Vol. 22, Dec. 1930, pages 1284–1290; **II. Pure sulfur Compounds in Hydrocarbon Materials in Contact with Nickel Catalysts.** Joseph C. Elgin. pages 1290–1293.
Five references. It is shown that a reduction in the sulphur content of naphthas is effected by passage, in the vapor phase, over a nickel or an iron catalyst, nickel being the more efficient. Sulphur may be completely removed in contact with the initially sulphur-free nickel catalyst, but the catalyst undergoes a decrease in activity as sulphurization proceeds. Nickel and iron catalysts do not absorb from the liquid phase all sulphur present in the naphthas. The second part of this article has four references. The results indicate that the sulphur content of naphthas containing relatively large proportions of thiophene sulphur will be the most difficult to reduce by catalytic methods. MEH(9)

Aluminum and Aluminum Alloys as Materials of Construction in the Chemical Industry. (Aluminium und Aluminiumlegierungen als Baustoffe in der chemischen Industrie.) Dornauf. *Metallbörse*, Vol. 20, Aug. 30, 1930, page 1913.
Experience in using pure Al, Al-Si and Al-Mg alloys is described. Duralumin and Al-Cu are not useful, but must be plated with pure Al. Pure Al (99.5–99.8%) is used to handle N acids and bases, concentrated HNO_3, organic compounds and in the dairy, brewing and food industries. Its disadvantages are poor casting properties and low tenacity. Al-Si and Al-Mg alloys have twice the strength of pure Al, cast well, and have as high chemical corrosion resistance. The Si alloy is used for valve bodies, stirrers, mixers, filter frames, retorts, evaporators, acid equipment and contact apparatus and the Mg alloy for pump cylinders, elevator buckets and stills. Often laboratory corrosion tests give results different from actual practice, due to voltage produced under liquids by contact with other metals or due to welding. WHB(9)

Lightening of Rolling Stock by Use of Aluminum Alloys. (La legerement du materiel roulant par l'emploi des alliages d'aluminum.) A. Dumas. *Aciers Spéciaux, Métaux et Alliages*, Vol. 6, Apr. 1931, pages 193–200.

Examples of weight saving through use of Al alloys and some account of the extent to which they are used in rolling stock all over the world. HWG(9)

Applications of Nickel in the Electrical Industries. (Les applications du nickel dans les industries electriques.) M. Ballay. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 471–492, 21 references.
Résumé dealing with electrical resistivity, magnetic and thermo-electric properties of nickel alloys, use of Ni steels in alkaline storage batteries and brief comment on Invar and Konel. See also *Metals & Alloys*, Vol. 2, Sept. 1931, page 176. HWG(9)

The Use of Vanadium Steels in American Railroads. (L'emploi des aciers au Vanadium dans les chemins de fer americans.) R. Cazaud. *Aciers Speciaux, Métaux et Alliages*, Vol. 6, Apr. 1931, pages 189–191.
The use of V steel is actually very important in U. S. for construction of locomotive and railroad material. C-V steel used consisted of 0.5% C, 0.80% Mn and 0.20% V also with 1.0% Cr. GTM(9)

Corrosion Resistant Steels. R. L. Duff (Standard Oil Development Co.). *American Society for Steel Treating, Preprint* No. 9, 1931, 6 pages.
Paper read and discussed before the Boston Convention of the Society in Sept. 1931. The author discusses the application in the oil refineries for the new corrosion resistant steels. Study of each steel and each problem is emphasized. WLC(9)

HEAT TREATMENT (10)

Metallurgical Control for Cutting Tools. W. R. Breeler. *Heat Treating & Forging*, Vol. 16, Sept. 1930, pages 1185–1188.
Heat treating methods for these products must be very uniform. Microphotographs show correctly and incorrectly treated specimens due to fluctuations in heat. Ha(10)

Heat Treatment in Forging Steel. B. Saunders. Crosby-Lockwood & Son, London, 1930. Cloth, 5 × 7½ inches, 117 pages. Price 5 sh.
This is a small manual for the practical blacksmith. As a sample of the directions given, we may cite the following. "Springs are tempered by reheating until sparks are produced when a piece of ash or hazel wood is rubbed on."
Nitriding is mentioned. It is stated that "Nitrogen is deposited by chemical action in special electric furnaces, upon the surfaces of bright finished parts during periods ranging up to 3 or 4 days in length." There is no hint that any special composition of steel is required.
The author says "The best material for the production of drop forgings or stampings is very mild steel or wrought iron, in which the carbon is below 0.50%."
While the author refers to "red heat," and gives his directions for drawing in terms of temper colors, he devotes one chapter to pyrometers. The book is not written for the metallurgist. Indeed, the chief point in reviewing it is so that a metallurgist who might think from the title that it contained information for him, will know that it does not. It seems doubtful if the blacksmith will get much out of it either.—H. W. Gillett(10)-B-

Importance of Correct Heat Treatment of Aircraft Parts. F. T. Sisco. *Houghton's Black & White*, Vol. 3, Mar. 1931, pages 4–8.
To turn out absolutely reliable work, every factor entering into the heat treatment of aircraft parts must be scientifically controlled. Correct design and suitable materials are other important conditions. 3 main causes for failures are the hardening cracks originating in a notch, weakness due to temper brittleness and non-uniformity of heat treatment. They are more fully discussed and the proper methods for avoiding them are explained. Ha(10)

Heat-Treatment of Rails. (Les traitements thermiques des rails de chemins de fer et de tramways.) H. Viteaux. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 405–418.
The Sandberg, Neuves-Maisons, Nadiejinsky, Maximilian-Hütte-Rosenberg and the Kenney-Bethlehem processes are briefly described. Laboratory tests on Sandberg and Neuve-Maisons process rails are tabulated. Stanton repeated impact tests (distance of drop of the tup not stated) showed an average of 3500 blows to fracture for specimens from untreated rails, and 10,500 for treated rails, though the single blow impact averages were lower (1.87 against 2.40) for the treated rails. Service results on heat-treated rails have shown improved wear resistance and the scanty evidence so far available on fissures also indicates promise. Viteaux believes that heat-treated converter steel is a proper material for rails. See also *Metals & Alloys*, Vol. 2, Oct. 1931, page 219. HWG(10)

The Theory of Recrystallization. (Zur Theorie der Rekristallisation.) G. Tammann. *Proceedings World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 36, *Mining & Metallurgy*, Part 4, pages 117–138.

The Decarburization of Carbon Steels by Heating in Salt Baths. (Ueber die Entkohlung von Kohlenstoffstählen bein Erhitzen in Salzbädern.) A. Seuthe & E. H. Schulz. *Mitteilungen Forschungs-institut Vereinigte Stahlwerke*, Vol. 2, No. 4, 1931, pages 61–76; *Stahl und Eisen*, Vol. 51, June 25, 1931, pages 791–793.
In an effort to elucidate the reasons for the surface decarburization of C steels when heated in salt baths, the authors heated samples of a C steel (C: 0.84%, Si: 0.03%, Mn: 0.25%, P: 0.02%, S: 0.03%) for ½, 1 and 3 hrs. at temperatures between 800° C. and 1000° C. in salt baths of NaCl, NaCl + KCl (1:1), NaCl + $BaCl_2$ (1:1), NaCl + $CaCl_2$ (1:1), and $CaCl_2$ + $BaCl_2$ (1:1). After heating, the C content of the 0.5 mm. thick outer layer and the C content of the core was determined. The results are as follows:

Type of salt	Decarburization of outer zone %	Total Decarburization %	Decrease of weight	Depth of decarburization zone %
NaCl	18.5	3.99	2.83	0.080
NaCl + KCl	17.5	4.02	2.82	0.076
NaCl + $BaCl_2$	12.1	2.71	2.06	0.058
NaCl + $CaCl_2$	30.5	5.10	2.30	0.120
CaCl + $BaCl_2$	24.2	5.00	1.32	0.140

The mixture of 50% NaCl + 50% $BaCl_2$ shows the smallest decarburization, next NaCl + KCl and NaCl, which show practically the same decarburization of about 50% more than NaCl + $BaCl_2$. The decarburization was found to be due to the air O which is dissolved in the salt melts. This O reacts directly with the C of the steel; on the other hand, iron oxides are formed during the heating. Since the amount of oxides formed increases with the weight of the samples treated, the decarburizing effect of the salt melts increases gradually. Sulphates present in the salts are of minor importance in bringing about decarburization. The chlorides mentioned above do not decarburize in a direct way. GN(10)

The Surface Decarburization of Steel. W. E. Jominy. *Heat Treating & Forging*, Vol. 17, July 1931, pages 684–688, 725; Aug. 1931, pages 781–782.
An abstract of an investigation by the American Gas Association as to the cause of the often troublesome decarburization in hardening operations which have to give maximum surface hardness. The work done on this subject by former investigators is reviewed, and, since no conclusive results had been obtained, new tests on the influence of gases were undertaken. The test methods are described and results with steam, air, CO_2, N, H and mixtures of these are given in tabulated form. 9 conclusions can be drawn. Among them, the most important is that, beside moist H, CO_2 produces the greatest decarburization at temperatures of 1350° F. and above. When mixed with 50% steam, this deleterious action was greatly reduced. Absolutely pure N does not cause decarburization; commercial N, however, will do it. The pressure of the atmosphere and the rate of flow, also, have a certain influence. The more strongly oxidizing the furnace atmosphere is, the less is the tendency to decarburize. It is recommended that, besides the prevention of decarburizing, the prevention of scaling should also be attempted. This can be accomplished by heating in pure N. For details, the paper must be referred to. Ha(10)

Aluminum Alloys and Their Treatment. J. W. Urquhart. *Heat Treating & Forging*, Vol. 17, Feb. 1931, pages 155–156; Mar. 1931, pages 260–262.
The marked differences in the heat treatment of steel and light metal alloys are set forth. The latter are not so easily stabilized; the heating phase has to be continued for hours. While tempering is a rapid phase in steel treatment to partially soften the extreme hardness secured by rapid cooling, the tempering of the light alloy has to harden it still further. The constitutional changes occurring during the treatment of different light alloys, their composition and physical properties, mode and temperature of pouring and the processes of heat treatment are briefly reviewed. Ha(10)

Heat Treatment of Automotive Steels. J. W. Urquhart. *Heat Treating & Forging*, Vol. 16, Oct. 1930, pages 1295–1299; Nov. 1930, pages 1412–1416, 1418.
Present improved status in the heat treating practice of automobile springs, fenders and gears. Data on low C steels, Cr-V steels, Ni-Cr steels. Table giving the composition of 12 British steels (Ni, Ni-Cr and Ni-Cr-Mo) used for springs and gears. Ha(10)

Heat Treating by Program Control. S. A. Smith. *Heat Treating & Forging*, Vol. 16, Sept. 1930, pages 1163–1164; Oct. 1930, pages 1281–1284.

On the Various Methods to Favor Graphitization in White Cast Iron. H. Sawamura. *Proceedings World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 34; *Mining & Metallurgy*, Part 2, pages 307–357.
A favorable effect on graphitization, ranging from strong with Si to weak with P, was found with Si, Al, Ti, Ni, Cu, Co, P and an unfavorable one, ranging from weak with W and Mo to strong with Cr and S, was found with W, Mo, Mn, V, Cr, S. Au and Pt also favor graphitization. The effect of various gaseous atmospheres and different packing materials was studied. Chill cast metal is more readily graphitized than sand cast. Water quenching of white iron from 850° C. cuts the time required for graphitization down to about ¼ that required by unquenched material. Repeated quenching was tried on some samples; so the forms of the specimens must have been such that they did not crack on quenching. The article is too diffuse for adequate abstracting. HWG(10)

18-8, Correct Heat Treatment Essential. Charles A. Scharschu. *Metal Progress*, Vol. 20, Aug. 1931, pages 68–74, 106.
The decomposition of austenite in this alloy at temperatures 800–1500° F. with accompanying loss of corrosion resistant properties is discussed. Effect of hot and cold work followed by long draws at various temperatures, on the physical properties is shown graphically. The effect of cold work on the decomposition of the austenite is shown in tabulated magnetic properties. Annealing temperatures of 1900–2000° F. are recommended for most economical annealing, best fatigue and corrosion resistance. Effect of small amount of other alloys such as silicon, tungsten and molybdenum are briefly discussed. WLC(10)

Hardening (10a)

Steels Hardened Magnetically to 1000 Brinell. C. H. Desch, Sheffield, England. *Metal Progress*, Vol. 20, Sept. 1931, pages 87–88.
The writer describes combination heat treatment hardening, "cloudburst" work hardening and a magnetic treatment resulting in extraordinary high hardness in a high speed and C tool steel of over 1000 Brinell. WLC(10a)

Magnetic Hardening of Metals. Edw. G. Herbert. *American Machinist*, Vol. 74, June 25, 1931, pages 967–971.
A newly discovered method of superhardening steel is the cloudburst process in which hard steel balls, generally 3 mm. or ⅛ in. in diameter are caused to fall from a height of 4 m. at a rate of about half a million/min. and bombard hard steel articles placed in the shower. The result of this process is a great increase in hardness. The reason for this phenomenon was seen in a rearrangement of the atoms under the bombardment. The author tried to bring about a similar hardening effect by rearranging the steel atoms under the influence of magnetic fields. Even materials regarded as non-magnetic such as Al, brass, etc. responded to this treatment and became harder. The hardness obtained by the cloudburst process is, however, greater. The tests are described and curves are reproduced. Ha(10a)

Cyaniding and Salt Bath Working. J. W. Urquhart. *Heat Treating & Forging*, Vol. 16, Aug. 1930, pages 989–993.
General discussion of salt baths for heating or hardening; temperature ranges of various salts and salt mixtures, preparation and freeing of grease of materials to be treated. Case hardening cyanides and their application are described. Ha(10a)

The Effect of Temperature of Quenching Medium on the Hardening of Steel. M. Mikami. *Kinzoku no Kenkyu*, Japan, July 1931, pages 398–402.
The present writer investigated the effect of temperature of quenching medium on the hardening of steel of 0.59, 0.89 and 1.28% of C. The size of specimen was 25 mm. in diameter. In the temperature range 0–50° C. of quenching water, the hardening decreases very slowly, but from 50 to 60° C. very rapidly. This critical range depends of course upon the size of the specimen. As for refined rape-oil, the hardness increases in the range 40–50° C., because of the diminution of viscosity of the oil, and then slightly diminishes up to 150° C.; if the quenching is not severe, a small minimum is observed in the vicinity of 70° C. This abnormal change has been explained as the combined effect of viscosity and of vaporization. KT(10a)

Annealing (10b)

The Method of Continuous Annealing and the Fundamentals of Heat Transfer in the Continuous Oven. (Das Durchzieh-Glühverfahren und die Grundlagen der Wärmeübertragung in Durchziehöfen.) O. Junker. *Zeitschrift für Metallkunde*, Vol. 23, May 1931, pages 158–160.
Chiefly mathematically descriptive of temperature and heat transfer conditions. Continuous belt annealing permits uniform heating. The velocity of the heating and the heat itself may be regulated at will, as well as heating and cooling ranges. These new features of gradation in heat-treatment permit the production of superior material with respect to deep-drawing and grain size. Upon the basis of the Newton law of cooling, an equation is developed for the course of the belt temperature. The mean heat transfer number, α, is determined for a charge of brass strip from experimental values by the use of the equation developed. This number is made up of 3 components: the heat conductivity of the separating air layers, convection in these layers and radiation exchange. The last component is the chief one, accounting for 91.5%. RFM(10b)

Bright Annealing and Other Operation in Controlled Atmospheres. J. F. Schrumm (Process Engrg. and Equipment Corp.). *Metal Progress*, Vol. 20, Oct. 1931, pages 77–80, 100.
Batch and continuous type furnaces for annealing non-ferrous metals in controlled atmospheres to prevent discoloration are described. WLC(10b)

The Reduction of Natural Tensions by Annealing. (Die Verminderung von Eigenspannungen durch Anlassen.) R. Mailänder. *Krupp'sche Monatshefte*, Vol. 12, June 1931, page 139–147.

Natural tensions are the results of elastic deformation which may be due to any mechanical or thermal cause. Their magnitude is dependent on the existing elastic deformations and the elasticity modulus of the material. The theoretical relations of these existing deformations and those produced by heating are treated and investigated for means of reducing the inner tensions by heating. The method of annealing is described and a tension diagram is given showing the relation of tension to total elongation. Test results for a chrome-nickel steel are reproduced in curves and diagrams. It is shown that this method permits the determination numerically of the magnitude of the tension remaining after annealing. The results are valid only for a state of tension in one axis and cannot be applied directly to large pieces of material where transverse tensions also take place. 9 references supplement the paper. The Bright Annealing of Copper and Its Alloys. O. S. Haskell. *Electrical Manufacturing*, Vol. 8, Sept. 1931, pages 39–40.

EFFECT OF ANNEALING ON THE PROPERTIES OF COPPER AT ROOM TEMPERATURE (BARDWELL)

Annealing of copper wire changes radically the tensile strength, conductivity and elongation. Accordingly, the annealing process varies with the use the wire is to be given. The effect of annealing on copper wire depends not only on the length of time the heat is applied, but the rate at which the wire is heated. Annealing time varies with the size of the wire. These factors require accurate control of annealing furnaces. Advantages of the various types of annealing furnaces are discussed. Increased conductivity and elongation are gained at the expense of tensile strength, and all 3 of these vary with increasing temperature. Notice that there is a point beyond which increased temperature results in decreased conductivity and elongation, and increased tensile strength. WAT(10b)

Case Hardening & Nitrogen Hardening (10c)

Modern Case-Hardening Practice. Francis W. Rowe. *Heat Treating & Forging*, Vol. 17, Apr. 1931, pages 372–373; May 1931, pages 475–479; July 1931, pages 721–722, 725.

A review of steels used for case hardening and their compositions, furnaces for case hardening, carburizing compounds, heat treatment after carburizing, quenching media and nitrogen hardening. See also *Metals & Alloys*, Vol. 2, Oct. 1931, page 220. (10c)

Nitriding Analyses—Their Physical Properties and Adaptability. R. S. Sergeson & M. M. Clark. *Machine Shop Practice (A.S.M.E. Trans.)*, Vol. 53, Jan.-Apr. 1931, pages 9–16.

A great number of microphotographs, curves and illustrations show the field of application for nitrided parts, their structure and physical analysis. The influence of heat treatment is also shown in test results. Ha(10c)

Thermo-Diffusion of Elements in Steel. John H. Hruska. *Heat Treating & Forging*, Vol. 16, Nov. 1930, pages 1397–1401, Dec. 1930, pages 1530–1533; Vol. 17, Jan. 1931, pages 35–39.

The treating of steel by heating in an atmosphere or surrounding it by other materials is fully discussed. 2 diagrams are given which show clearly in which way the diffusion of non-metallic and metallic elements goes and the manner in which it is carried out. The diffusion of specific elements into iron and steel can be represented by the equation $X = \dfrac{E}{\left(\frac{E}{e}-1\right)\left(\frac{d}{D}\right)^n+1}$ where X is the percentage of the diffusing element on the surface, e the percentage of the diffusing element in the core, d the distance from the surface corresponding to X and D the total depth of penetration or case. The exponent n must be obtained from at least 3 experimentally determined points of the curve and then assumes the value $n = \dfrac{\log (E-x)e - \log (E-e)X}{\log d - \log D}$, where x means the third point of the curve. The thermo-diffusion of C, O, N, Al, Cr, V and Si are treated in detail. Temperatures of the diffusion, time of the process diffusion, concentration and testing are described and curves illustrating the results are given. Ha(10c)

Carburizing with Various Gases. E. C. Cook. *Fuels & Furnaces*, Vol. 8, Dec. 1930, pages 1667–1668.

The various gases used for this purpose are enumerated and their particular properties are briefly described. Ha(10c)

Short Time Nitriding. John J. Egan (Union Carbide and Carbon Research Lab.). *American Society for Steel Treating, Preprint* No. 19, 1931, 16 pages; *Fuels & Furnaces*, Vol. 9, Oct. 1931, pages 1165–1166.

Paper read and discussed before the Boston Convention of the Society in Sept. 1931. The author describes several methods of shortening the time of nitriding. The duplex cyanide treatment; use of ammonia and nitric oxide, ammonia with nitrogenous compounds and activated sand as a packing material; the use of the electric spark in the nitriding chamber and ultra violet radiation on the specimen are discussed. Results of a wear test on resulting nitrided cases are reported. Ha+WLC(10c)

The Role of Energizers in Carburizing Compounds. George M. Enos (University of Cincinnati). *American Society for Steel Treating, Preprint* No. 36, 1931, 23 pages.

Paper read and discussed before the Boston Convention of the Society in Sept. 1931. A study of various energizing materials is presented showing that carbonates are not essential. It is shown that O must be present either as air or in an oxide that will readily yield O to form oxides of C. Some materials are shown to have a negative energizing effect. WLC(10c)

Cyanide Heat for Alloy Steel. D. A. Holt (Roessler & Hasslacher Chemical Co.). *Metal Progress*, Vol. 20, Oct. 1931, pages 68–72.

The utility of cyanide for the case hardening of certain high grade materials is discussed. Control of depth and quality of case is discussed in reference to a number of special steels such as SAE 2345, 3135, 3335, 4140, 5150 and 6150. WLC(10c)

The Action of Molecular Nitrogen on Iron-Carbon Alloys. H. H. Gray & M. B. Thompson. *Journal Society Chemical Industry*, Vol. 50, Sept. 18, 1931, pages 353–357T.

A 0.37% C steel (polished) was heated for 5 hrs. in highly purified N at temperatures from 100° to 1100° C., cooled to room temperature in N and examined under the microscope. The outstanding features were as follows: Up to 550° C., the chief effect of the N is to react with the available Fe and form iron nitride (at the same time, pearlite is attacked). At 600° C., the reaction product and the structure change. Between 700° and 800° C., the destruction of the pearlite, which practically completes itself at 800° C., gives rise to new and definite structures. At 850° C., the transparent layer makes its appearance. Analysis indicates that this layer contains N. From 850° to 1100° C., the formation of the transparent layer takes place with increasing ease. Its formation coincides with a falling off in the C removal. The transparent layer shows signs of developing crystals from a supercooled fused mass and there is a certain amount of evidence that the amount of secondary crystallization can readily be influenced by the rate of cooling. Other effects were obtained which can probably be explained by the observations of Fry and Schottky (*Stahl und Eisen*, Vol. 43, 1923) that Fe and N form several nitrides and that the action of ammonia on Fe-C alloy results in the formation of several complicated Fe-C-N compounds, the composition of which is unknown. An 0.84% C steel was nitrogenated at 750° and 1100° C. In neither case was there satisfactory evidence of the formation of the transparent layer. No lamellar pearlite was found. At 1100° C., the surface contained many small prisms. The chief conclusion drawn from these 2 nitrogenations was that C is first attacked by the N and the transparent layer is not formed. A zone of maximum decarburization was shown to exist between 700° and 800° C. The photomicrograph at 800° C. indicates complete decarburization. VVK(10c)

Nitriding in Industry. J. Muller. *S. A. E. Journal*, Vol. 29, Sept. 1931, pages 236–240.

Steel for nitriding must be held to close limits in the essential elements such as Cr, Mo, and Al and the material should be heat treated and drawn to limits that are relatively hard for machining to provide a core of sufficient strength to support the case. The temperature of nitriding affects both the surface hardness and the hardness gradient within the case, the maximum hardness being in inverse ratio to the temperature of the reaction. The effects in hardness both at the surface and at various depths in the case under different conditions are represented by graphs. Active circulation of the ammonia in the furnace promotes uniformity of the product. A furnace design to give reversing circulation is described and illustrated. The material selected for the lining of the furnace must be such as not to interfere with the reaction between the ammonia and the material under treatment. The advantages of a new duplex method of treatment, in which the work is done at 2 different temperatures, are mentioned. Questions in the discussion led to the statement that new types of steel suitable for nitriding are under development but only one type is now recognized as suitable. Experiences were given in regard to distortion or growth of the metal during nitriding. References were made to continuous and other types of nitriding furnaces suitable for large production. WAT(10c)

Recent Applications of Nitrided Steels. (Recenti applicazioni dell acciaio nitrurato.) A. Quagliotto. *La Metallurgia Italiana*, Vol. 23, Sept. 1931, pages 824–832, 13 figures.

Examples of wear resistance of cams, gears, cylinders, brick dies, etc., etc. in actual service are cited, the life being compared with that of the material which it replaced. The examples chosen show a huge increase in life. HWG(10c)

Case Hardening. A Survey of the Results of Recent Investigations. (Die Einsatzhärtung. Eine Zusammenfassung neuer Forschungsergebnisse.) H. Müller. *Archiv für Eisenhüttenwesen*, Vol. 5, July 1931, pages 57–62.

The paper deals, first, with the conditions which cause a normal or abnormal structure in steel. The media of case carburizing and nitriding are then considered. CO causes a gradual transition of the zones of various C contents, a slow carburizing and a small C content of the edge. CO under pressure speeds up the carburization. Pressure does not accelerate the carburization with hydrocarbons. Hydrocarbons show no gradual transition of the carburized zones. This can be improved by increasing the temperature of carburization. The most favorable carburizing temperature is between 850° and 900° C. In order to avoid the formation of a cementite network, the cooling velocity after carburization should be as rapid as possible. GN(10c)

High Frequency Oscillations. Influence on Metals and Alloys. M. G. Mahoux. *Iron & Steel Industry & British Foundryman*, Vol. 4, June 1931, pages 290, 312.

Under the influence of high frequency oscillations, a Cr-Ni-Mo steel held for 9 hrs. at 500° C. and in a current of ammonia gas had a Vickers hardness of 1033 at the surface with a penetration of nitriding of 0.35 mm. The same material under identical conditions but without the high frequency oscillations gave no measurable hardness increase. With the same treatment, an austenitic valve steel had a surface hardness of 1035 with no variation in hardness without oscillations. The Cr plating on a mild steel penetrated to a depth of 0.35 mm. after 9 hrs. at 530° C. under the influence of high frequency oscillations. The plating was unaffected without oscillations. For the same conditions, a cast iron was covered with C deposition and decarburized superficially to a depth of 0.8 mm. CHL(10c)

Quenching (10d)

Identification of Quenched Duralumin. L. Pessel. *Heat Treating & Forging*, Vol. 16, Nov. 1930, pages 1417–1418.

A method is given by which spots appearing on tests make it possible to determine whether a piece has been hot or cold quenched. Photographs illustrate the difference. Ha(10d)

Progress in the Quenching of Steel. J. W. Urquhart. *Heat Treating & Forging*, Vol. 17, July 1931, pages 672–674.

For the production of the hardest steel surfaces, a certain critical speed of heat abstraction from the piece to be quenched must be provided. The utility of various cooling media are treated in detail: the descaling action of soda coolants which take off any adherent film of oxide rapidly and so expose the true steel surface to the quenching medium, the special combination coolant for steel stripping where the question of penetration does not enter (on account of the thinness), and the quenching of heavy masses. For heavy masses, a method of combined quenching and tempering is being used extensively. It consists of immersing the steel in the coolant until the surface appears black. This method, while quite safe, does, however, not develop the full tensile property of the steel throughout the mass. Ha(10d)

Quenching (10d)

Aqueous Solutions of Ethylene Glycol, Glycerine and Sodium Silicate as Quenching Media for Steel. Thomas E. Hamill. *Bureau of Standards, Journal of Research*, Vol. 7, Sept. 1931, pages 555–571 (Research Paper, Bureau of Standards No. 357.)

The quenching characteristics of aqueous solutions of ethylene glycol, glycerine and sodium silicate were studied by means of temperature-time cooling curves on small cylinders of a 0.96% C steel quenched in solutions of various concentrations and temperatures. Center cooling curves are given for cylinders one-half inch in diameter by 2 inches long, quenched in aqueous solutions of ethylene glycol and glycerine at atmospheric temperature. Surface and center cooling curves are given for aqueous solutions of 2 lots of sodium silicate having different soda-to-silica ratios, namely, 1:4 and 1:2.5. These 2 silicates are designated in this report by the ratios. Tne effect of increasing the temperature of solutions of the 1:4 sodium silicate from 20° to 80° C. was studied. The characteristics of these cooling curves and a study of the hardnesses and structures produced suggest that these sodium silicate solutions would be useful for obtaining cooling rates from slightly less than that obtained with water to that of oil. 4 concentrations of the 1:4 sodium silicate having specific gravities corresponding to 4.6°, 9.5°, 13.2° and 16.7° B and 2 of the 1:2.5 sodium silicate, 12.4° and 28.8° B, were found which gavei ntermediate cooling rates between those obtained with water and with oil at atmospheric temperature. Some trouble was experienced with the instability of certain of the aqueous solutions of the 1:4 sodium silicate. The stability of these solutions was greatly increased by the addition of 2% by volume of a solution of sodium hydroxide of specific gravity 1.065. The wide variations in cooling produced by check tests on aqueous solutions of ethylene glycol and of glycerine indicate that these solutions may not be particularly useful as media for the quenching of steels. Quenching experiments with "stepped" bars of a 1.06% C steel indicate that sodium silicate solutions can be used at atmospheric temperature to provide coolants with graded cooling speeds between those of water and oil. WAT(10d)

The Mechanism of Quenching High-Carbon Steel Tools. P. J. Haler. *Fuels & Furnaces*, Vol. 8, Dec. 1930, pages 1653–1659.

The scientific principles involved in hardening and quenching are explained by the 4 allotropic forms of pure Fe. The quenching of the various types of high C or case-hardened steels, the mechanism of cooling and the effect of heat on the stream lines around the piece being quenched are discussed. Ha(10d)

Drawing (10e)

Tempering of Special Steels Quenched from High Temperatures. (**Étude sur les revenus d'aciers spéciaux hypertrempés.**) A. Michel & P. Benazet. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 327–333.

Discussion of high C, medium and high Cr, CrW, CrCo and CrCoW, air quenched from 1150° or 1250° C. 11 dilatometer curves are given to show the decomposition of the austenite retained on quenching. HWG(10e)

Three Overlapping Reactions Occur during Tempering. Correspondence from A. Portevin, Paris, France. *Metal Progress*, Vol. 20, Sept. 1931, pages 89, 114.

The writer presents briefly the results of an extensive study of tempering reactions involving the study of several physical properties or characteristics of the several phases resulting in tempering. WLC(10e)

Aging (10f)

The Precipitation Hardening of Iron-Phosphorus Alloys. (**Ueber die Ausscheidungshärte der Eisen-Phosphor-Legierungen.**) W. Köster. *Archiv für Eisenhüttenwesen*, Vol. 4, June 1931, pages 609–611; *Stahl und Eisen*, Vol. 51, June 25, 1931, page 797.

The author investigated the hardenability of an alloy with 1.5% P and 0.06% C by quenching from 1000° C. and tempering in 1/2 hr. steps up to 800° C. The hardness increases between 450° and 700° C. with a maximum between 550° and 600° C. In a similar manner, the electric conductivity and the magnetic properties were studied. The conductivity increases up to 725° C. and then decreases. The solubility of P in α-Fe obviously increases above 725°. In measuring the magnetic properties, the alloy shows a behavior which is in conformity with the known experience with the decomposition of supersaturated solid solutions. The small increase of magnetism between 200° and 350° C. points to a segregation of cementite. A rapid increase occurs between 600° and 700° C. and must be considered to be due to the decomposition of the solution supersaturated with P. The measurements are in perfect agreement with the microscopic examination. In slowly cooling, Fe_3P crystallizes in needles while the saturation of P in α-Fe decreases. In quenching above 700° C., the amount of the needles decreases and, in quenching above 1000° C., the alloy is composed only of homogeneous α-crystals. The decomposition of the above supersaturated solid solution is characterized between 650° and 700° C. by the appearance of numerous fine crystals. The increase of hardness during tempering evidently is not accompanied by a microscopically noticeable change of structure, whereas the increase of the coercive force coincides with the visible separation. In etching the tempered specimens, it was observed that spots which had been deformed previous to the tempering are more readily attacked than the non-deformed matrix. GN(10f)

Properties of Sheet Steel Change with Age. Correspondence from A. M. Cox. *Metal Progress*, Vol. 20, Sept. 1931, page 85.

The writer presents results showing an aging effect in cold rolled sheet steel involving an increase in ultimate strength and Rockwell hardness and a decrease in the elongation after 2 months' aging, further aging for 6 months is without additional effect. WLC(10f)

Aging in Low-Carbon Steels. A. Allan Bates (Case School of Applied Science). *American Society for Steel Treating, Preprint* No. 13, 1931, 23 pages.

Paper read and discussed before the Boston Convention of the Society in Sept. 1931. 23 micrographs show the structures studied. The author shows low carbon steel to be capable of age-hardening to a 50% increase in its ultimate strength and Brinell hardness. The hardness is due to submicroscopic particles of precipitated carbide. 25–30 days are required for the completion of this effect at room temperature. Very notable hardening can be shown on aging 30 minutes at 100° C. (212° F.). Age-hardening may be avoided by slow cooling from temperatures near A_1 or by drawing for a suitable length of time to precipitate the carbide in sizes which will not cause hardening. WLC(10f)

The Influence of Cold Work on Aging Following Quenching. (**Die Beeinflussung der Vergütung durch Recken nach dem Abschrecken.**) W. Fraenkel. *Zeitschrift für Metallkunde*, Vol. 23, June 1931, 172–176.

The effect of cold work immediately following quenching on the velocity of aging of 3 typical age-hardening Al alloys was studied by measurements on Brinell hardness, tensile strength, elastic limit and electrical conductivity. The sensitivity toward working varies and is especially great with alloys containing Zn and Li. The increase of electrical resistance with aging in duralumin is smaller with the pre-worked alloy. RFM+EF(10f)

JOINING OF METALS & ALLOYS (11)

Fluxes for Welding and Brazing. A Contribution to the Chemistry of the Fluxes. (Flussmittel zum Schweissen und Hartlöten. Ein Beitrag zur Chemie der Flussmittel.) E. LUEDER. *Schmelzschweissung*, Vol. 10, Aug. 1931, pages 197–201; Sept. 1931, pages 220–222.

The action of a flux consists of a dissolving process, the physical and chemical conditions of which are given in detail. The temperature is of great importance; for the different processes, the following temperatures are required:

Aluminum brazing	550°–630° C.
Aluminum welding	660° C.
Brazing with silver fluxes	700°–850° C.
Brazing with brass fluxes	850°–950° C.
Welding of copper alloys	900°–1000° C.
Welding of copper	1100° C.
Welding of gray castings	1200°–1300° C.
Hammer welding of iron	1300°–1350° C.
Welding of nickel	above 1400° C.
Welding of non-rusting steels	above 1450° C.

The various fluxes are described. The so-called universal fluxes are noted as unsatisfactory; they usually cover only a certain range. It is much better to apply a flux suitable for the purpose in question. Ha(11)

Hard Facing in the Steel Industry. W. B. MOORE (Haynes Stellite Co.). *Metal Progress*, Vol. 19, June 1931, pages 77–80.

The author describes and discusses the application of a hard face attached by welding or brazing to surface subjected to severe conditions of wear. WLC(11)

Brazing (11a)

The Process of Increased Strength in Brazing of Gray Castings, Malleable and Steel Castings. (Das Verfahren erhöhter Festigkeit bei Grau-, Temper-, Stahlguss-Hartlötungen.) H. STREBEL. *Die Schmelzschweissung*, Vol. 9, July 1930, page 165.

The strength of a brazed joint can be greatly increased by reinforcing with a steel wire insert analogous to reinforced concrete. This wire is first soldered on to the material. Ha(11a)

Can Brazing Be Considered as Non-Objectionable Construction or Joining Method? (Kann die Hartlötung als einwandfries Konstruktions- oder Verbindungselement betrachtet werden?) FELIX WECKWERTH. *Schmelzschweissung*, Vol. 10, Aug. 1931, pages 191–195; Sept. 1931, pages 228–232.

Brazing should be done with torches which cannot heat cast iron above 950° C. In general, the flame should be neutral or adjusted to have a little excess of O. The best formation of solid solutions can be expected with slow heating, annealing of longer duration during the melting stage, and subsequent annealing at slow cooling if the structure of the cast iron and the solder is not to be injured. Using borax as a flux, the same results can be obtained as with special fluxes and solders for cast iron. Swelling fluxes must be avoided. Good fluxes which come off after cooling have the advantage that a subsequent machining of the seam is feasible. Too small seams should be avoided; the seams should have a greater width in front of the flame than on the opposite side. The greatest strength can be obtained with a shearing-soldered connection offering the greatest diffusion surface; the strength is so great that the joint can be used as construction methods for rebuilding of castings. Ha(11a)

Soldering (11b)

Soldering 18-8 Stainless. KENNETH T. MACGILL. *American Machinist*, Vol. 74, Mar. 5, 1931, page 386.

A special solder and a special flux has been developed to aid in soldering stainless alloys. Does not give composition of either solder or flux. Joints in Allegheny metal have shown 8000 lbs./in.² on tensile pull tests. RHP(11b)

Repair of a Cooling Mantle of a Tensile Testing Machine by Soft Soldering. (Ausbesserung eines Kühlmantels an einer Zugmaschine durch Weichlöten.) W. K. RAABE & M. WIENCKE. *Autogene Metallbearbeitung*, Vol. 24, July 15, 1931, page 215.

Description of the way in which the work was done. Soldering took only 17 mins., even when the piece had previously been Cu coated. Ha(11b)

Welding & Cutting (11c)

Arc Welding Joints in Steel Structures. R. W. VAN KIRK. *Iron & Steel Industry & British Foundryman*, Vol. 4, Sept. 1931, pages 407–409.

General. See also *Metals & Alloys*, Vol. 2, Sept. 1931, page 179. CHL(11c)

Ways of Proving a Good Weld. T. R. WATTS. *Electrical World*, Vol. 98, Oct. 10, 1931, pages 645–648.

Four means of proving a good weld are: (1) close watch over trained operators; (2) tack hammer and stethoscope tests; (3) γ-ray photos surpass X-ray method; (4) magnetic methods show most promise. Careful training and classification of workers is now conducted with good effect. The stethoscope discloses some flaws. The Sperry electromagnetic method is outlined. In this test, iron filings or powder are sifted onto a piece of paper placed on the weld. The picture formed indicates any possible flaws. A weld test meter is being perfected. It is claimed to be practically indifferent to the depth at which the fault is buried and under the most favorable conditions gives results from which the approximate efficiency of the joint can be determined by reference to calibration curves made on comparable test specimens. It is best employed with the electromagnetic test. WHB(11c)

The Testing of Welded Seams. (Ueber die Prüfung von Schweissnäten.) H. SCHMUCKLER. *Autogene Metallbearbeitung*, Vol. 24, Aug. 1, 1931, pages 231–234; *Forschungsarbeiten auf dem Gebiete des Schweissens und Schneidens mittels Sauerstoff und Azetylen*, Series 6, 1931, pages 37–41.

The author has developed a testing apparatus for welded seams. He claims that this apparatus gives direct insight into the quality of the weld which cannot be obtained with magnetic testing or by other simple methods. He uses a small milling tool with 45 degree head with which a direct incision into the seam is made. The spot where the incision is made is so small that the weld is not weakened. It takes about 1–2 mins.; the miller is driven by a little electric motor of 400 watts. The incision can be closed again by welding or left and painted over. Ha(11c)

Welding Progress in Railway Shops. JAMES M. VOSSLER (Southern Pacific Lines). *Welding*, Vol. 2, Sept. 1931, pages 599–601.

Experience in railway shop welding has taught the importance of preheating and postheating parts to reduce residual stresses. Careful cleaning of welds is also necessary. The author explains the procedure for various railway shop welding applications. He believes that the next 5 years will show improvements in welding electrodes and welding procedure which will result in the removal of restrictions imposed on welding by the Interstate Commerce Commission and railway officials. The Metallurgy of Fusion Welding. (Metallurgische Betrachtungen über die Schmelzschweissung.) F. RAPATZ. *Stahl und Eisen*, Vol. 51, Feb. 26, 1931, pages 245–253.

Report 168 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The suitability of filler metal for welding purposes depends upon a slow and undisturbed melting-off of the filler metal and a good combination of the deposited metal with the base metal. Welding with uncoated electrodes causes non-metallic inclusions when the electrode is the negative pole. This type of welding is most suitable for use in welding soft steel. The method cannot yet be used in welding higher C steels and alloy steels. Good melting-off of uncoated electrodes when connected to the positive pole is obtained in welding almost any type of steel; however, the penetration of the deposited metal into the base metal is not remarkable. In welding with alternating current, coated electrodes can always be used but uncoated electrodes are not suitable. In welding with direct current and with thickly coated electrodes, the electrode is always the positive pole. In gas welding, the rods should be free from larger amounts of non-metallic inclusions. The composition of the weld depends on the absorption of gases, the oxidation of the various components and the combination with the welded piece. The effect of alloys upon the properties of the weld, as well as the effect of the heat upon the structure of the parts around the weld are discussed. Larger parts of the structure of the piece are more affected in gas welding than in arc welding. In welding high alloy steels, the piece is extremely affected by air hardening. In testing welds, all processes of deformation are complicated due to the variety of the zones affected. GN(11c)

Pipe Welding in Architecture. **(Die Rohrschweissung in der Architektur.)** H. Juergens. *Autogene Metallbearbeitung*, Vol. 24, Oct. 15, 1931, pages 305–307.

A few examples of applications in banisters, railings, stairs, etc., are illustrated. Ha(11c)

Arc Welding Joints in Steel Structures. R. W. Van Kirk. *Western Machinery World*, Vol. 22, Sept. 1931, pages 405–406.

Recommended current values and sizes of bare and lightly coated electrodes for various sizes of welds are given. The advantages of arc welding are pointed out and the necessity of careful inspection is emphasized. WAT(11c)

Fabrication of Copper Products by Welding. S. J. Mashl. *Metal Stampings*, Vol. 3, July 1930, pages 643–644.

Abstract or paper read before the Chicago Section of the American Welding Society. See "Copper Welding in the Chemical Industry." *Metals & Alloys*, Vol. 2, Mar. 1931, page 70, MS(11c)

Welded Tube Construction. G. H. Handasyde. *Aircraft Engineering*, Vol. 3, Oct. 1931, pages 249–250.

The methods employed in the manufacture of welded tube members for air craft construction of the A. V. Roe & Co., of Manchester, England, are briefly described and shown. WAT(11c)

Welding. A. B. Arganbright (Wheeling Steel Co.). *Iron & Steel Engineer*, Vol. 8, Aug. 1931, pages 360–361.

A brief discussion of all types of welding, gas, arc, atomic hydrogen, resistance and thermit. The manufacture and inspection of welding wire are taken up. WHK(11c)

Gas-Welded Pipe Structures. **(Gasgeschweisste Rohrbauten.)** Otto Bondy. *Schmelzschweissung*, Vol. 10, Oct. 1931, pages 243–245.

A few examples of special structures and details of their construction. Ha(11c)

The Helical Precision Autogenous Welding Process in the Manufacture of Welded Metal Hose. **(Die Schraubenförmige Präzisions-Autogenschweisserei bei der Fabrikation von geschweissten Metallschläuchen.)** W. Greiner. *Autogene Metallbearbeitung*, Vol. 24, Oct. 15, pages 303–305.

The paper gives a detailed description of the manufacture of metal hose for pressures of several hundred atmospheres which are entirely tight and safe. The equipment is described; hose of from 6-2000 mm. inner width can be made; the thickness of the metal ribbon varies from 0.5 to 2.5 mm Ha(11c)

The Construction of Autogenously Welded Structures of Profile Irons. **(Die Ausbildung von autogen geschweissten Säulen aus Profileisen.)** E. Greger. *Die Schmelzschweissung*, Vol. 10, Oct. 1931, pages 246–247.

The most advantageous procedure for building up a column is demonstrated by means of an example. Ha(11c)

Autogenously Welded Connections of Electric Conductors. **(Autogen geschweisste Verbindungen elektrischer Leitungen.)** L. Gavanda. *Autogenschweisser*, Vol. 4, No. 3, 1931, pages 41–42.

The making of perfect contacts between electric conductors by welding instead of by terminal clamps is recommended, especially for heavy conductors, bus bars, etc. The ends to be welded are best heated in a charcoal fire to red heat before the actual welding with the oxy-acetylene flame is done. The cost for welding 2 bus bars of 10 × 100 mm. is given as about 10 Rm. Ha(11c)

Advantageous Practical Application of Acetylene Welding and Its Saving Compared with Older Joining Methods. **(Vorteilhafte praktische Anwendung der Azetylenschweissung und ihre Ersparniss gegenüber den älteren Verbindungsmethoden.)** H. Holler. *Forschungsarbeiten auf dem Gebiete des Schweissens und Schneidens mittels Sauerstoff und Azetylen*, Series 6, 1931, pages 21–27; *Autogene Metallbearbeitung*, Vol. 24, Aug. 1, 1931, pages 223–230.

Describes and illustrates some difficult and complicated welds of evaporators, large boilers, branches of large pipes, radiators, etc. Ha(11c)

Automatic Gas Cutting—Central Control and Multiple Torch Operation. R. E. Helmkamp. *Journal American Welding Society*, Vol. 10, Sept. 1931, pages 36–38.

Paper presented before the Fall Meeting of the American Welding Society in Boston, Sept. 1931. Advantages of multiple torch machine cutting are increased production in same elapsed time, with no increase in labor cost and floor space required. TEJ(11c)

Looking Ahead in the Welding Industry. W. D. Flannery. *Welding*, Vol. 2, Sept. 1931, pages 595–596.

It is forecast that the future dwelling house will be of welded steel construction. The various transportation systems offer great possibilities for the advancement of welding. TEJ(11c)

Welded Instead of Cast. **(Geschweisst statt gegossen.)** H. Holler. *Die Schmelzschweissung*, Vol. 10, June 1931, pages 142–147.

Several examples of auxiliary tools, jigs, sprocket wheels, holding devices for lathes, etc., are illustrated, showing the many advantages of fusion welding over the casting of such devices. Ha(11c)

All Ships Will Be of Welded Construction. Eric E. Ewertz. *Welding*, Vol. 2, Sept. 1931, pages 609–610.

Lack of trained designers, supervisors and welders has, in the past, retarded welded ship construction. Most shipyards are now equipped for welding. Within 5 years, all ships for all purposes will be the all-welded form of construction. A list of all-welded vessels built during the past 5 years, is included. TEJ(11c)

Welding of Brass and Copper Piping. DeW. Endicott. *Journal American Welding Society*, Vol. 10, July 1931, pages 26–29.

Laboratory investigations indicate that Cu, red brass, alpha brass and Munts metal pipe and tubing can best be welded by using the short-bell type of joint and high strength bronze welding rod. Brass and Cu piping and tubing are being used in constantly increasing amounts where a permanently trouble-free water supply system is desirable. Specifications covering the oxy-acetylene welding of steam and hot water brass piping are given. TEJ(11c)

Riveting (11d)

Riveting of Veneered Light-Metal Sheets. **(Ueber die Nietung von fournierten Leichtmetallblechen.)** F. Thomas & A. Westlinning. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 3, Apr.-June 1931, pages 173–181.

Great sums are wasted every year in the transport of dead masses. For instance, in transporting a person weighing 75 kg. by railroad, the weight of the vehicle is about 500 kg., by street car, 150 kg., by motor coach, 200 kg. or by four passenger automobile, 250 kg. To bring about improvement, experiments have led to the use of light metals for chassis and body. Satisfaction has resulted in both economy and safety. Sweating within the vehicle, however, resulted from the ready heat conductivity of these metals. This condition was prevented by laying wooden veneers on the metal sheets either on one side or on both sides. The method of riveting these sheets together is illustrated and test method and results are described. Ha(11d)

WORKING OF METALS & ALLOYS (12)

Melting & Refining (12a)

Desulphurization of Iron and Steel by Acid and Basic Slags. (La désulfuration de la fonte et de l'acier au moyen de laitiers acides et basiques.) A. Possenti. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 815–818.

The chemical reactions involved in desulphurising are discussed and the heats of formation of oxides and sulphides listed. The use of Italian lavas rich in leucite, and containing 9 to 11% K_2O is advocated. By magnetic concentration these can be brought up to 16 or 18%. Tests were made on 1 kg. crucible melts of cast iron previously made up with Fe S, and containing only about 0.1% Mn to avoid desulphurization by Mn. The Mn remained constant, and a slight pick-up of Si was shown. Starting with 1 kg. of iron containing 0.18% P, 0.80% S; 333 gr. leucite of 9% K_2O and 100 gr. CaO, the slag contained 1.25% S and the iron dropped to 0.10% P, 0.965% S. Another test on 1 kg. of iron with 1.42% P, 1.10% S; 250 gr. concentrated leucite of 17.5% K_2O and 50 gr. CaO, the slag contained 1.85% S and the iron fell to 0.75% P, 0.062% S. The S is said to be in the slag as K_2S, and to be thus made soluble so that the slag would be useful as fertilizer or the K_2S could be extracted with water. (No comment nor explanation is given as to the loss in P. The total weight of slag formed, which might have been greater than the weight of flux used through attack on the refractory crucible, is not given, but the total S charged is not accounted for if the slag weight is the same as that of the flux charged. The slag was not analyzed for P.) HWG(12a)

On the Steel Production in Coreless Induction Furnaces of Large Size. (Ueber die Stahlerzeugung im Kernlosen Induktionsofen grösserer Bauart.) F. Pölzguter. *Stahl und Eisen*, Vol. 51, Apr. 23, 1931, pages 513–520.

Report 207 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. The paper describes 2 coreless induction furnaces of 500 kg. and 1000 kg. capacity, respectively, installed at the Bochum Research Institute of the Vereinigte Stahlwerke. The production in tons/hr., the average power consumption and the oxidation losses are compared with those of arc furnaces. In comparing the heat balances of a 7 ton arc furnace and the one ton induction furnace, the fundamental difference of current losses is described. Points of improvement of the efficiency of induction furnaces are noted. Information is given as to the metallurgy of induction furnaces and the quality of steels made. GN(12a)

The Production of High Grade Cast Iron. (Die Herstellung von hochwertigem Gusseisen.) Richard Moldenke. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, July 17, 1931, pages 573–576.

According to American standards, high grade cast iron is defined as having at least 35 kg./mm.^{2} tensile strength; but nowadays higher values, especially for the alloys with Ni and Cr, are quite common: The different methods of producing such material in crucible, cupola, flame and electric furnaces are discussed. Directions are given for mixing, addition of scrap and analyzing. The particular advantages of the cupola furnace especially in the form of duplex furnace, are pointed out. To obtain a strictly first-rate material, however, the electric furnace is recommended despite its higher cost for investment and operation. Ha(12a)

Purchase of Raw Materials for the Open-Hearth. (L'achat des matières premières pour fours Martin.) F. Le Personne & L. Marbais. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 117–134.

Deals with calculation of the charge and the use of scrap. HWG(12a)

The Melting Shop of the Appleby Iron Company, Limited. Arthur Robinson. *Iron & Steel Industry & British Foundryman*, Vol. 4, May 1931, pages 261–263; June 1931, pages 309–312; *Journal Iron & Steel Institute, Advance Copy* No. 15, 1931, 22 pages.

A description of the plant, equipment and steel-making and casting practices are given in detail. JLG+CHL(12a)

Motions of the Bath so Far Unobserved in Induction Furnaces. (Bisher unbekannte Badgewegungen bei Induktionsöfen.) E. Fr. Russ. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Feb. 20, 1931, pages 165–166.

See "The Electrodynamic Motions in Induction Furnaces," *Metals & Alloys*, Vol. 2, Apr. 1931, page 83. Ha(12a)

Hot Metal Open Hearth without Use of Scrap. (Procédé Martin à charge liquide sans addition de ferrailles.) S. Surzycki. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 149–150.

Two furnaces are used, one being charged with hot metal only to $^2/_3$ its capacity. When the other furnace is tapped, $^1/_3$ of its finished charge is run into the other furnace from the ladle in lieu of scrap. HWG(12a)

The Melting of Dense Bronzes for High Pressures. Defects and Their Consequences. (Das Erschmelzen von dichter Bronze für Hochdruckbeanspruchung. Fehler und deren Folgen.) M. Schied. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, July 24, 1931, pages 603–604.

For pressures of more than 100 atmospheres, only one alloy can be used, as for instance of the following composition: 83% Cu, 6.5 Sn, 8.5% Zn, 1% Ni with an addition of 1% of the charge of phosphorus copper. This alloy has an especially dense and uniform texture. All constituent metals should be as pure as possible. The influence of gases is discussed; it is usually harmful. The liquid metal should be properly deoxidized and the melting time should be as short as possible. Some practical instructions regarding the melting process are given. Ha(12a)

Melting Tool Steel in the Basic Electric Furnace. J. P. Gill & M. R. Trembour (Vanadium Alloys Steel Co.). *Metal Progress*, Vol. 20, Oct. 1931, pages 73–76.

The operation and advantages of the basic electric melting process are discussed. Manipulation of slags, handling of certain alloying elements, spoon ladle tests for temperature, deoxidation and pouring are discussed. WLC(12a)

Thermal Balances and Fuel Costs of Malleable Melting Furnaces. J. H. Hruska. *Transactions & Bulletin American Foundrymen's Association*, Vol. 2, June 1931, pages 20–36.

A report of systematic studies of metallurgical heat balances of melting furnaces together with actual fuel costs. An appendix of thermal data for each type of furnace is given. See also *Metals & Alloys*, Vol. 2, July 1931, page 134. CHL(12a)

Melting Nickel-Chromium Alloys in Hydrogen. C. J. Smithells, S. V. Williams & E. J. Grimwood (General Electric Co., Ltd.). *Institute of Metals, Advance Copy* No. 582, Sept. 1931, 12 pages.

Equipment for melting the alloys in an induction furnace in H is described. The alloys can be allowed to cool in H or the H can be replaced by N and the alloys poured. If all of the oxides are removed by H, the alloy solidifies without the formation of blow-holes. Various grades of raw materials were used, and it was found that alloys made from the less pure materials had a longer life at high temperature. Life tests also confirmed the superiority of the alloy containing 70% Ni, 20% Cr and 10% Mo. The addition of 1% Si to this alloy increased its life at high temperature. Ductile Ni and Ni-Cu alloys have been produced by H melting without the use of other deoxidizers. 6 references. JLG(12a)

Casting & Solidification (12b)

Piston Rings Cast by Centrifugal Process Have Close Grain and High Modulus of Elasticity. William A. Oubridge (British Piston Ring Co., Ltd.). *Automotive Industries*, Vol. 64, Mar. 1931, pages 516–517.

Castings made by the centrifugal casting machines for producing piston rings, cylinder liners, valve seats and brake drum liners for automotive uses. Molten metal placed in a container, which is revolved at high speed; the liquid metal is thus projected in an outer direction toward the interior surface of the mold. The result is a tubular casting, the exterior of which conforms to the shape of the mold. A small machine can turn out 20 to 25 castings for 3 in. rings/hr. or 1200 for a 48-hr. wk. Illustrates larger machines for producing castings from 6 in. to 14 in. and 14 in. to 30 in. diameter. Metal, 60% pig iron and 40% centrifugal or other scrap, taken from an ordinary type foundry cupola. Castings are easily machinable with high grade high-speed steel at 45 to 50 ft./min. British vehicles have almost all changed to centrifugally cast cylinder liners of either cast iron or nickel chrome. Photomicrographs of centrifugally and sand cast iron show close comparison. DTR(12b)

Chilled Casting and Pseudo-Chilled Casting. (Hartguss und Pseudohartguss.) Hugo Patsch. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Mar. 13, 1931, pages 225–227.

A definition of the meaning of chilled casting is given and the differences between white and gray iron are explained. It is stated that the quality depends not only on the mixing of the constituents and pouring temperature, but the temperature during melting in the furnace and the duration of melting are of extreme importance for the quality. The hardness of the iron is determined not only by contents of Si or P or Mn and S, but by the operation of the furnace as a whole. Ha(12b)

Casting Aluminum and Copper Alloys by the Permanent Mold Method. Jos. Pignone. *Modern Machine Shop*, Vol. 4, Sept. 1931, pages 20–24, 26.

For quantity production with good appearance, die casting has now gained a foremost position. For alloys with a melting point above 1500° F., the permanent mold method is most often applied. No pressure on the metal is used; the metal is simply poured by gravity so that the cast steel mold is exposed to high temperatures only at atmospheric pressure and deterioration is reduced to a minimum. The arrangement of molds, furnaces for melting material and their construction are discussed. The induction furnace is the most economical if electric power can be bought at 1.5c/kwhr. and if the production amounts to at least 2000 lbs./hr. The alloy most commonly used contains 92% Al and 8% Cu; it develops a tensile strength of 18,000–20,000 lbs., a yield point of about 16,000 lbs. and an elongation of 2–3%. With additions of Ni and Mg, however, other alloys with still better characteristics can be produced. Ha(12b)

Castings for Bronze Gears. Francis W. Rowe. *Metallurgia*, Vol. 3, Apr. 1931, pages 215–218; May 1931, pages 27–28; June 1931, pages 61–62.

A discussion of methods for producing heavy duty bronze gears. The density of gears forms an index of their suitability. The use of chills in casting is discussed. Excellent gears can be made by centrifugal casting. Due to the rapid cooling the constituents in bronze castings are not represented by the equilibrium diagram. The inhomogeneity produced is advantageous. The variation in properties with Cu-Sn ratio is discussed. P hardens the alloys, and in effect can be used to replace some of the Sn, but the alloys are embrittled by a high P content. The effects of Pb, Zn and Ni are also discussed. JLG(12b)

Solidification Experiments on Metal Alloys Using Pressure up to 20,000 Atmospheres. (Kristallisationsversuche an Metallegierungen bei Drücken bis zu 20,000 at.) G. Welter. *Metallbörse*, Vol. 20, Nov. 22, 1930, page 2588.

It was found that, by applying pressure to molten alloys during their solidification, the properties of the alloys could be changed. The improved quality of materials solidified under pressure is evident when comparing the fracture and the microstructure of these alloys to normal chill castings. In the case of the Al-Si alloy, the eutectic composition is changed. The eutectic is normally around 12% but if pressure is applied during solidification, the eutectic composition is between 17% and 18%. See also *Metals & Alloys*, Vol. 2, Dec. 1931, page 297. WHB(12b)

The Calculation of Occurrences in Cooling and Freezing of Liquid Metal. Part I. (Die rechnerische Behandlung der Abkühlungs- und Erstarrungsvorgänge bei flüssigem Metall. I.) C. Schwarz. *Archiv für Eisenhüttenwesen*, Vol. 5, Sept. 1931, pages 139–148.

In order to get an insight into the cooling and freezing conditions of liquid metals, the author starts with calculative considerations which consider the freezing at the beginning of the cooling process as the problem of the contact of 2 bodies, the extensions of which are very large in the direction vertical to the faces of contact. These calculations are, then, used to elucidate the conditions of the freezing of ingots in ingot molds and of the cooling of steel and pig iron in ladles. The effect of superheating, melting temperature, temperature of the mold and mold material upon the velocity of freezing and the temperature distribution of the ingot before stripping were studied. Relations are established between mold temperature and contact temperature (mold wall-steel) for various superheating temperatures. Similar relations are established between ladle wall temperature and minimum superheating temperature (for various freezing temperatures) in order to avoid the formation of bears. The formulas given can be used to repeat the calculations noted above under similar conditions. GN(12b)

Rolling (12c)

Spraying System for Descaling Hot Steel. J. E. Holveck (V. P. Aldrich Pump Co.). *Iron & Steel Engineer*, Vol. 8, Aug. 1931, pages 362–368.

The use of high pressure water spray descaling hot slabs in the various stages of rolling is described. Data on the amount of water required, pressure and nozzle spacing are given. The author favors an hydro-pneumatic accumulator for taking care of the peak demand (which may be 300% above the average) instead of pumps of total capacity equal to the peak demand. An improved type of pump is described. WHK(12c)

Roll Pass Design. Part XXVI. W. Trinks (Carnegie Institute of Technology). *Rolling Mill Journal*, Vol. 5, Feb. 1931, pages 99–105.

Discusses design of 3-high blooming mills and 2-high tandem blooming mills and illustrated operation of each type with examples, giving complete tables of data on rolls, passes, working characteristics, etc. with reasons for special design features. In the 3-high mill, the groove in the middle roll meets corresponding grooves in both the top and bottom rolls. Top and bottom passes alternate, but edging occurs only with the bottom passes. Drafts are much heavier in the bottom passes. The rolls in 3-high mills work with higher stresses than those in 2-high mills and undergo considerable wear. Both 2-high reversing mills and 3-high mills are hard on steel because of the heavy draft, the high speed of deformation and the use of box passes. The objections are overcome by the newly-developed "monkey rolls" used in 2-high tandem blooming mills. These operate more slowly than a reversing mill and produce excellent blooms. Each roll has but one groove and permits box, oval or diamond passes. Edging is performed after each pass. The torque and horse-power requirements are quite low. JN(12c)

Explanation of Spreading During Rolling with the Help of the Surface Strain Theory. (**Die Klärung der Breitungsfrage beim Walzen mit Hilfe der Spannungsflächenhypothese.**) W. TAFEL & W. KNOLL. *Metallwirtschaft*, Vol. 10, Oct. 16, 1931, pages 799–806.

20 references. A theoretical discussion. Starting with Tafel's hypothesis of tension triangles a formula for calculating spreading, or increase in width, during rolling is developed, which can be universally applied, in contrast to older formulas. The influence of roll diameter and width of bar on spreading was investigated and is explained by the spreading hypothesis. The application of the formula to Pb, Cu and Al is elaborated. 3 sets of curves are given by which spreading can be calculated in a short time. CEM(12c)

The Orientation of Rolled Aluminium. J. THEWLIS. *London, Edinburgh and Dublin Philosophical Magazine & Journal of Science*, Vol. 10, Nov. 1930, pages 953–961.

Deals with flat-rolled and square-rolled aluminum. For the flat-rolled, no definite direction in the crystal can be identified with the rolling direction or the normal direction. A square-rolled rod rolled from an aluminum rod possessing random orientation has the same orientation as a cold-drawn aluminum wire. RHP(12c)

Theory and Practice of Rolling Steel. W. TAFEL, translated by RICHARD RIMBACH. Penton Publishing Co., Cleveland, 1931. 2nd edition. Cloth, $6\frac{1}{4} \times 9\frac{1}{4}$ inches, 304 pages. Price $6.00.

Although the first edition was only published in 1927, a second edition has been required. Minor revision has been made throughout, and the chapter on "Power for and method of driving roll trains" has been amplified.

The book also covers the theories and rules of rolling, technical conceptions of rolling, pass design and arrangement of rolls, merchant bars and special shapes. It is replete with illustrative drawings, which aid greatly in understanding the geometry of rod design and the mode of deformation of the metal.

This is not merely a cook-book of empirical roll designs for the production of a given shape; instead it deals with fundamental principles and their application, so presented that the reader may grasp the reasoning required for a successful solution of a problem in roll pass design even though it may not be among those dealt with in detail in the book.—H. W. Gillett (12c)-B-

The Production of Copper Tubes. A. SCHUMMEL. *Metal Industry*, London, Vol. 39, July 31, 1931, pages 98, 101.

Abstracted from *Technische Blatter*. The method of manufacture of seamless copper tubes depends on dimensions of tubes; the Mannesmann process is most general, though tubes up to 50 mm. diameter are made by press processes. PRK(12c)

The Use of Roller Bearings in Rolling Mills. (**Ueber die Einführung von Rollenlagern in Walzwerken.**) G. PALMGREN. *Revue Technique Luxembourgeoise*, Vol. 23, May-June 1931, pages 109–121.

Several installations are described to illustrate the wide use recently attained by roller bearings of the SKF type. Construction details are given with curves showing the difference in power consumption between ordinary and roller bearings. Beside saving in energy consumption, the rolls themselves are less subject to wear because they do not get out of alignment so easily and the product is, therefore, of more uniform gage. Ha(12c)

The Heating of Billets for Merchant Mills. U. A. PETERS. *Rolling Mill Journal*, Vol. 5, Feb. 1931, pages 109–110, 124.

Stock billets range in size from $1\frac{3}{4}$ in. square to 8 in. square. For rolling bar sections of soft steel, billets must be heated uniformly at a temperature between 2150° and 1550° F. The old type of in and out heating furnace has an average thermal head of 1500° F. with a heat penetration of $\frac{1}{8}$ in./min. The continuous heating furnace has an average thermal head of 600° F. with a heat penetration of only $\frac{1}{20}$ in./min. The latter discharges a far more uniformly heated billet. Heating losses vary inversely with the width of the bar. JN(12c)

Fabrication of Automobile Body Sheet. (**Fabrication des tôles pour carrosserie d'automobiles.**) D. TACCONE. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 313–319.

Describes various methods and indicates that continuous rolling and continuous normalizing will ultimately have to be adopted everywhere. HWG(12c)

Shearing & Punching (12e)

Design and Construction of Hot Saws for Cutting Heavy Sections. A. B. PEARSON. *Transactions American Society of Mechanical Engineers*, Vol. 52, Part 1, *Iron & Steel*, pages 105–112.

Includes discussion. See *Metals & Alloys*, Vol. 2, July 1931, page 135. (12e)

Metal Working in Power Presses. E. V. CRANE. *Metal Stampings*, Vol. 4, Apr. 1931, page 336.

Abstract of a paper presented at the New York Meeting of the American Institute of Mining & Metallurgical Engineers, week of Feb. 16, 1931. See *Metals and Alloys*, Vol. 2, May 1931, page 106. JN(12e)

Machining (12g)

Machining Aircraft Cylinder Heads. H. C. DECKARD. *Western Machinery World*, Vol. 22, Sept. 1931, pages 389–391.

There are 28 operations required before the cylinder barrel and head of an aircraft engine are ready to be assembled. These operations are described briefly. The cylinder assembly is composed of 14 parts; these are enumerated. WAT(12g)

Results with Widia Tool Metal. (**Leistungsergebnisse mit Widia-Werkzeugmetall.**) A. FEHSE. *Maschinenbau*, Vol. 10, No. 5, 1931, pages 161–173.

Because of its long life and the possibility of applying it in thin layers on the carrying metal, Widia metal is very economical. The cutting velocity is 70 m./min. for high speed steel. The cutting capacity for C steel is 0.65 kg. in 1.7 min.; for high speed steel it is 6.1 kg. in 3.2 min.; for Widia, 58 kg. in 16.5 min. It can be used equally well for cutting and drilling insulating materials (marble, slate, glass, etc.) Ha(12g)

Application of Drill Jigs to Metal Stampings. CARLE SIZALANCZY (Westinghouse Electric & Mfg. Co.). *Metal Stampings*, Vol. 3, July 1930, pages 655–658.

When holes smaller in diameter than the thickness of metal in a stamping must be produced, or when the walls between punches are frail, it has been found advantageous to drill the required holes by means of drilling jigs. Illustrates construction of both single and multiple jigs. MS(12g)

The Action of Cutting Tools. H. A. SCHWARTZ. *Iron & Steel of Canada*, Vol. 14, Mar. 1931, pages 45–46.

A short article, accompanied by 5 diagrams, in which the importance of tool design, the causes of tool failure, and the purpose of cutting oil are discussed. Some consideration is given to the factors controlling tool life and reference is made to the work of various experts in this field. OWE(12g)

New Investigations on the Theory of Cutting and Machineability. (**Neue Untersuchungen zur Schnitt theorie und Bearbeitbarkeit.**) F. SCHWERD. *Stahl und Eisen*, Vol. 51, Apr. 16, 1931, pages 481–491.

Report No. 171 of the Committee on Materials of the Verein deutscher Eisenhüttenleute. Includes discussion. After discussing the results of previous investigations, the author describes a new apparatus to study the occurrences on the cutting edge and summarizes the results of his tests in machining open hearth steel, cast iron, Al, Cu and bronze with various depths of cut and different cutting speeds. The investigation particularly aims to study the occurrences on the cutting edge of the tool. This was done by applying the spark cinematography which allowed 10 pictures to be taken within $\frac{1}{1000}$ sec. with a time of exposure of $\frac{1}{1,000,000}$ sec. In cutting tough materials with a slow speed, a crust is formed on the edge of the tool. At high velocities, no crust is formed. In cutting open hearth steel, the speed was determined above which no crust occurs. The crust formed continually changes in size in time intervals of several tenths of a sec. The relations between the crust and the surface condition of the material machined were studied. The surface of the material is always destroyed when a crust is formed. Cracks originate as do also distortions of the surface up to one half of the depth of cut when the crust is formed with slow cutting speeds. High speeds and, therefore, the absence of crusts give sound and smooth surfaces. The crystal grains near the surface are distorted in slow cutting. A crust is formed even with light depths of cut (0.05 mm.). No distortion of the structure occurs in high speed cutting. In machining brittle materials, as cast iron or aluminum, the material is split, torn and destroyed without formation of a crust upon the cutting edge. GN(12g)

Cooling and Lubrication in Machining Cast Iron. (**Kühlen und Schmieren bei der Gusseisenzerspannung.**) A. WALLICHS & K. KREKELER. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, June 19, 1931, pages 493–495.

Comprehensive tests were made in machining cast iron dry and wet with an oil emulsion. Under proper conditions, the cutting velocity could sometimes be increased by 50%, but in any case, a considerable gain could be stated. Ha(12g)

Boring and Reaming of Iron, Copper, and Aluminum Alloys. (**Untersuchungen über das Senken and Reiben von Eisen-, Kupfer- und Aluminium-Legierungen.**) H. SCHALLBROCH (Tech. Hochschule, Aachen). Thesis for Dipl-Ingr., E. Wedler & Co., Aachen, July 18, 1930, 23 pages, 36 figures, 16 references.

Curves are shown for energy required in boring and reaming holes of different diameters with different depths of cut at varying feeds, in cast irons (10,000 and 30,000 lbs./in.^{2} tensile; 87 and 178 Brinell); 0.17% C steel (53,000–114); 0.45% C steel (85,000–182); 0.35% C, $1\frac{1}{2}$% Ni, $\frac{1}{2}$% Cr heat-treated steel (120,000–232); 0.35% C, $3\frac{1}{2}$% Ni, $\frac{3}{4}$% Cr heat-treated steel (135,000–285); cast brass of 63% Cu, 35% Zn, 2% Pb (31,000–55); red brass of 85% Cu, 5% Sn, 7% Zn, 3% Pb (25,000–80); leaded bronze of 80% Cu, 8% Sn, 12% Pb (25,000–67); gun metal, 84% Cu, 14% Sn (34,000–128); in 99.3% Al (14,000–25); silumin $86\frac{1}{2}$% Al, 13% Si, $\frac{1}{2}$% Cu (24,000 to 33,000–48) and in heat-treated Lautal, 94% Al, 4% Cu, 2% Si (54,000 to 60,000–95). The data are too extensive for abstracting in detail. The effect of different coolants upon the power required and on the excess of actual diameter over nominal diameter was studied. With cast iron the average increase in diameter of hole was slightly less with a cutting emulsion than with rapeseed oil with which in time it was slightly less than with mineral oil. The steels gave best results with emulsion, mineral oil next, rapeseed third. The copper alloys gave the same results with emulsion and rapeseed oil, mineral oil being slightly poorer. The aluminum alloys showed much greater differences in size of hole than did the other alloys, a mixture of 5 parts gasoline, 4 parts turpentine worked best, rapeseed next, emulsion third. On all alloys, dry cutting gave worse results than cutting with a coolant, though only slightly so on the copper alloys.—H. W. Gillett (12g)-B-

New Developments in Machining Aluminium and Its Alloys. R. L. TEMPLIN. *Metal Industry*, London, Vol. 38, Apr. 24, 1931, pages 433–434.

Condensed from a paper read before the Society of Automotive Engineers at Detroit. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 43. PRK(12g)

Tool Engineering. J. M. RITTNER. *Western Machinery World*, Vol. 22, Sept. 1931, pages 392–394.

The general requirements necessary for the efficient operation and working of jigs is set forth briefly. WAT(12g)

Standards for Surface Finishes. S. M. RANSOME (Barber-Colman Co.). *American Machinist*, Vol. 74, Apr. 9, 1931, page 581.

The Barber-Coleman Co. has prepared a set of sample bars showing 6 different finishes from a dead smooth surface to a rough machine finish. These with a brief printed description are distributed throughout the shop and drafting room as a standard for finishes. RHP(12g)

Accurate Testing of Machines by Energy Measurements. (**Genauigkeitsprüfung von Werkzeugmaschinen durch Energie Messung.**) CLAUS SCHUMACHER. *Maschinenbau*, Vol. 10, July 18, 1931, pages 415–418; July 2, 1931, pages 446–449.

The significance of accurate testing of machines in motion by measurement with a recording watt meter is presented. The importance of conditions previous to testing is emphasized. For the special case of a multi-axle motor, an accurate representation of the calculation of 4 drum brakes for artificial production is made. The essence of testing the charge is discussed by means of diagrams. An evaluation of the Watt lines of multi-axled motors is made, while the basis for a numerical estimate of motor standardization is presented in a new way. This new conception may express the efficiency of the motor with reference to its use in practice, and may also evaluate numerically the efficiency of the curve showing the voltage used. MAB(12g)

Drawing & Stamping (12h)

Commercial Types of Power Presses. Part III. Single Action Drawing Presses and Attachments. E. V. CRANE (E. W. Bliss Co.). *Metal Stampings*, Vol. 4, Apr. 1931, pages 317–320.

For single action drawing or redrawing, the presses commonly used are the standard stroke presses, the straight side and gap frame types of presses and the long stroke reducing presses. All of these have the ordinary crank motion. The slow draw drive presses use a modification of the crank motion. These give a uniform and constant drawing velocity but materially speed up the return stroke. The rack and pinion type of press is used for extremely long strokes. This has a limited speed of 16–36 ft./min. but the return speed is faster than the down stroke. A new type of crank motion press developed for greater speeds shows an average velocity of 108 ft./min. in reducing brass shell. In the Fulton-Sylphon process, each draw is accomplished by means of a number of relatively short crank motions in a long-frame, horizontal press. Reductions of 40–50% in wall thickness per operation are reported at speeds of 80–320 in./min. Al, Cu, Zn and brass tubing have been produced of remarkable uniformity in lengths up to 10 ft. JN(12h)

Plastic Drawing of Sheet Steel into Shapes. E. V. CRANE (E. W. Bliss Co.). *American Society for Steel Treating, Preprint* No. 18, 1931, 21 pages.

Paper to be read and discussed before the Boston Convention of the Society in Sept. 1931. Principles developed in the study of the plastic deformation (cold) of metal into round shells are discussed. Surface markings developed during the working, plastic movement, breakage and strain hardening, annealing troubles and die construction are discussed. WLC(12h)

Increasing Value of Scrap Metals from Stamping Operations. JAMES SILBERSTEIN. *Metal Stampings*, Vol. 3, Aug. 1930, pages 717–720.
Unless a stamping plant operates a foundry, the scrap is sold. Price paid depends on its freedom from contamination. Outlines classifications necessary for obtaining highest prices for Cu, brass, bronze, Ni, Monel metal, German silver and Al. Describes some rapid tests for classifying alloys of similar appearance but different chemical composition. MS(12h)

Investigations on the Course of Deformation of the Technical Shaping Methods. (Untersuchungen über den Formänderungsverlauf bei technischen Formgebungsverfahren.) E. SIEBEL & H. HÜHNE. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 13, No. 3, 1931, *Report* No. 173, pages 43–62; *Stahl und Eisen*, Vol. 51, May 7, 1931, page 597.
After theoretical considerations, the authors give the result of their investigations on the state of deformation of a material during drawing, pressing, stamping and rolling. GN(12h)

Investigations on the Power Consumption in Pressing and Stamping. (Untersuchungen über den Kraftbedarf bein Pressen und Lochen.) E. SIEBEL & E. FANGMEIER. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 13, No. 2, 1931, *Report* No. 172, pages 29–41; *Stahl und Eisen*, Vol. 51, May 7, 1931, page 597.
The authors found in their investigations that the power consumption in pressing and stamping can be determined from the work required for shaping which is the product of deformed volume, resistance to deformation and the principal change of shape. Theoretical considerations lead to the development of a formula to express the power consumption. The theory was tested in pressing and stamping experiments with lead and later in investigating the various technical processes of pressing and stamping. GN(12h)

Estimating Material Requirements for Stampings. J. K. OLSEN. *Metal Stampings*, Vol. 3, Oct. 1930, pages 897–900.
Gives table of commercial and preferred gates or sizes, exact weight in lb./in.^{2}, and constant for weight in lbs. per 100 pieces plus 5% scrap for sheets, strips and bar stock of various metals and alloys used in stamping manufacturing. MS(12h)

Simplified Method of Determining Weight of Sheet or Strip Stock. J. K. OLSEN. *Metal Stampings*, Vol. 3, July 1930, pages 663–664.
Gives typical calculations and table for simplifying the computation of brass stock for production stamping jobs. MS(12h)

Lubricants for Deep Drawing. MAURICE RESWICK.(Penna. Lubricating Co.). *Metal Progress*, Vol. 20, Sept. 1931, pages 69–73.
A paper read before the Sept. Convention of the American Society for Steel Treating in Boston. Failure to recognize the real purpose of lubricants for deep drawing has led to much expensive "out and try" search for satisfactory lubricants. The primary function of a lubricant is to prevent metal to metal contact between the work and the dies and to decrease the sliding friction to a minimum. The quality of a lubricant must be measured by its performance on the job. The qualities essential are (1) film strength that will not break down under the operating pressures and thin out under the temperatures resulting from the heat of friction; (2) oiliness or low coefficient of friction between die and work must be obtained; (3) the lubricant must adhere to the metal surface and spread ahead of the working pressure; (4) must be easily cleaned from the work; (5) must have no corrosive action on the dies or work; (6) the lubricant must be stable; (7) it must have no physiological effect; (8) odors or perfuming should be avoided; (9) the lubricant should undergo no changes in properties with change in climatic conditions; (10) the drawing compound should be inexpensive on the basis of quality and amount of work done per die. Not all these ideals may be attained simultaneously and every grease is a compromise. Lubricants must be developed according to conditions. Tallow and mineral oil are discussed. Use of fillers and compounding of oils are discussed. Typical analyses are given with this discussion. WLC(12h)

Handbook of Deep-drawing Technology. (Handbuch der Ziehtechnik.) W. SELLIN. Julius Springer Verlag, Berlin, 1931. Cloth, $6^1/_2 \times 9^1/_2$ inches, 360 pages, 371 figs. Price 32 RM.
This is a book that would deserve translation into English. It discusses the principles of the deformation during deep-drawing, the effect of die form and die clearance, the difficulties met, graphic and mathematical methods for calculation of the amount of stock necessary to form a given piece, and goes into great detail in the discussion of all kinds of presses, shears and accessories. Copious illustrations, photographs, sketches and curves are used. The book is beautifully printed, and has an index. The important factors in deep-drawing are the sheet, the die and the machine. Each is discussed in detail. Curves are given showing the Erichsen values for various alloys in various thicknesses. Evaluation of quality of sheet seems to be chiefly through tensile and Erichsen values, though hardness testing is described, and a drawing test in which the power required can be measured, is also mentioned. Some attention is paid to annealing methods and equipment, and brief mention is given to heat-treatment of dies. The metallurgical aspects of the problem are not as adequately treated as the mechanical ones, however. Cost estimation and the economics of production receive some attention as do precautions for the safety of the operators. The handbook is a distinct addition to the literature of the subject, and an English edition would be acceptable.—H. W. Gillett (12h)-B-

Pressing Plant for the Production of Seamless Drawn Hollow Bodies. (Presswerk zur Herstellung von nahtlos gezogenen Hohlkörpern.) S. WEIL. *Stahl und Eisen*, Vol. 51, Sept. 3, 1931, pages 1119–1120.
Detailed and illustrated description of a press plant producing seamless bodies up to 1450 mm. diameter and 8500 mm. length. GN(12h)

How Steel Bends. D. C. BAILEY. *American Machinist*, Vol. 74, June 4, 1931, pages 865–867.
Explanation of a method for the simple calculation of the exact width of metal required for any particular section in folding or rolling metal channels and moldings. A monographic chart is developed and its application is illustrated. Ha(12h)

Sheet Steel, Its Drawing Quality. THOMAS DOCKRAY (Eastern Rolling Mill Co.). *Metal Progress*, Vol. 20, Oct. 1931, pages 54–59.
The effect of the principal mill operations of hot rolling, normalizing, box annealing, cold rolling, steel quality, and age on the properties of sheet steel are discussed. Application of test methods to selection of material is discussed. Much space is devoted to the interesting subject of aging and its effect upon the properties of sheets. WLC(12h)

Pickling (12i)

Black Pickling of Brass. (Schwarzbeizen von Messing.) K. SCHUCH. *Oberflächentechnik*, Vol. 18, Aug. 4, 1931, page 163.
The following saturated solution is recommended: 150 g. copper carbonate, 750 g. ammonia and 150 g. water. The pickling should be over in 3–8 mins. If the solution is heated to 40–50° C., it takes less time. Several modifications of the method are discussed according to the purpose and the composition of the objects. Ha(12i)

Action of Inhibitors in Metal Pickling. (Ueber die Wirkungsweise von Sparbeiz-zusatzen bei der Metallbeizung.) H. PIRAK & W. WENZEL. *Metallbörse*, Vol. 20, Nov. 15, 1930, pages 2539–2540; Nov. 22, 1930, page 2589.
A review of various theories. Some preference is given to that of Chappell, Roetheli and McCarty. WHB(12i)

Cold Working (12j)

The Construction and Uses of Shape Bending Machines. D. A. JOHNSTON (Kane & Roach, Inc.). *Metal Stampings*, Vol. 4, Feb. 1931, pages 121–126, 134.
Gives list of most common applications of bending equipment and describes and illustrates the 4 main classifications of benders, i. e., pyramid, pinch, wrap and full wrap, showing various vertical and horizontal types of each. Also discusses capacities of different types and sizes of machines and the roll arrangements and special and standard rolls employed in making the various bends. JN(12j)

The Design and Application of Straighteners. Part II. D. A. JOHNSTON (Kane & Roach, Inc.). *Metal Stampings*, Vol. 4, Mar. 1931, pages 215–219.
Most standard roll straighteners consist of a succession of staggered top and bottom rolls with the top rolls adjustable. Usually, only the bottom rolls are gear driven. To straighten a bar, the rolls are set to give it a series of new sweeping bends. These absorb all the original kinks and bends and remove most of the internal stress. To straighten angles, a one-way roll straightener is used which operates against the crotch. A two-way or combination straightener with both vertical and horizontal rolls is also used which operates against the back of the angle. Rotary straighteners are widely used for round bars, pipe and tubing where the highest accuracy is desired. Here, the work rotates between rolls tipped at an angle. One type straightens automobile axle shafts, drive shafts, etc., at a speed of 30 ft./min. Another type straightens bars at high speeds up to 450 ft./min. JN(12j)

The Institution of Automobile Engineers. Pressings for Automobiles. J. C. ARROWSMITH. *Automobile Engineer*, Vol. 21, July 1931, pages 272–278.
There has been a considerable tendency of late years to substitute cold pressings for hot, where possible. Hot pressing was formerly a necessity on account of the limited power available, but with the development of the powerful press equipment of to-day that difficulty has been largely overcome. At the same time, it has been necessary for the steelmakers to supply material suitable for cold pressings and considerable advances have been made in this direction. It is now possible to cold press all the members which go to make up a chassis frame and in many instances to punch all the necessary rivet holes during the blanking operation. The great advantage offered by cold pressing is that the cost of production is lower, since the rate of production is much higher and the wear on the dies is less severe since lubrication is possible. The strength and reliability of cold-pressed parts have for a long time been well established. It is occasionally put forward that, as it is necessary to use material of a lower initial tensile strength for cold pressing, the strength/weight ratio is higher in the case of hot pressings. It should, however, be borne in mind that while the physical properties of the steel of a hot pressing remain unchanged by the pressing operation, a cold pressed article is actually strengthened by the cold work put upon it. (12j)

Cracking of Cold Drawn Steel Bars. (Ueber das Aufreissen von kaltgezogenem Rundeisen.) W. FAHRENHORST & G. SACHS. *Metallwirtschaft*, Vol. 10, Oct. 9, 1931, pages 783–788.
4 references. Certain types of steel have a tendency to tear or crack, similar to brass, during cold drawing, polishing and automatic machining processes. Round bars containing 0.06 C, 0.41 Mn, 0.06 P and 0.04 S produced under various practices were hot rolled to 42 to 46 mm. diameter, then cold rolled in one pass to 40 mm. diameter and polished. 5 of the bars cracked during cold rolling. The cracking had no relation to the method of pouring or deoxidizing, top or bottom of ingot, diameter of hot rolled bar or out of roundness, impact strength or hardness of the finished bars. The impact strength of bars from Al killed ingots was 100% higher than from those not killed with Al, and those from the bottom of the ingot were 30% higher than from the top of the ingot. The internal longitudinal, tangential and radial strains remaining in the bars due to cold working were determined by drilling the bars stepwise and measuring changes in diameter and length. The results are shown graphically and are surprisingly high. Polishing lowers the strains considerably, especially in the center of the bars, while near the surface they are reversed. It is reasonable that with tangential strains of 30 kg./mm.^{2}, bars with minute inclusions near the surface or other slight defects will crack. 3 methods of preventing these strains are proposed: (1) annealing at 500° C., (2) straining the bars after drawing beyond the yield point, (3) increasing the reduction in diameter during drawing so that the metal flows when it leaves the die. CEM(12j)

Hardness of Metals and Alloys as a Function of Cold Work. (Les variations de dureté de certains métaux et alliages en fonction de l'écrouissage.) GUICHARD, CLAUSMANN & BILLON. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 527–532.
Study of various coinage alloys. The rate of hardening of Ag, Ni, Cu, aluminum bronze, coinage bronze, cupro nickel, Au-Cu and Ag-Cu alloys is plotted. Some show slow increase of hardness at the higher deformations, but after around 60% reduction, cupro nickel, Ni, aluminum bronze and coinage bronze do not get harder on further reduction. Some comment is made on methods of hardness determination by Baby Brinell on thin sheets. HWG(12j)

Influence of Initial Condition on Hardening of Metals and Alloys in Cold Work. (L'influence de l'état initial de certains métaux et alliages sur la variation de dureté par écrouissage.) GUICHARD, CLAUSMANN & BILLON. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 533–534.
The hardness curves of Cu, Ag and some of their coinage alloys, plotted against percentage deformation, are approximately parallel, but the curve for the material cold rolled from the as-cast condition lies higher than that for material rolled from the annealed condition. HWG(12j)

Bending Dies for Press Brakes. F. H. PFEFFERLE (Cincinnati Shaper Co.). *Metal Stampings*, Vol. 4, Apr. 1931, pages 325–328, 336.
Describes and illustrates the simple types of bending dies used in press brakes for making acute angles, hems, 90° bends and offset bends. These bends are all made by using combinations of the appropriate single dies in pairs. 4-Way bending dies are equivalent to 4 single dies. They are made square with an opening in each side and are used in combination with one or more single dies for forming a range of metals from $^1/_8$ to $^3/_8$ in. in thickness. Radius dies are used for making right angle bends of comparatively large radii. Special dies are employed for making U-bends. Solid dies require 2 or 3 operations to produce a U-bend with parallel sides, while a pair of folding dies will do this in one operation. JN(12j)

The Construction and Uses of Levellers. Part III. D. A. JOHNSTON (Kane & Roach, Inc.). *Metal Stampings*, Vol. 4, Apr. 1931, pages 309–312.
Gives photographs and descriptions of a number of commercial levelling machines for wide sheet and strip stock, including capacities, speed, type of rolls, nature of drive and means of lubrication of each. JN(12j)

Tammann's Investigations on Cold Working, Strain Hardening and Recrystallization. (Tammann's Untersuchungen über Kaltreckung, Verfestigung und Rekristallisation.) G. MASING. *Zeitschrift für Metallkunde*, Vol. 23, May 1931, pages 139–142, 14 references.
The well-known statements of Tammann concerning phenomena involved in the plastic deformation and recrystallization are summarized. EF(12j)

Overstrain of Metals. MAJOR A. C. MACRAE. His Majesty's Stationery Office, London, 1930. Cloth, 6 × 9½ inches, 369 pages. Price 1£ 1s.

By giving a gun forging a slight permanent set by means of hydraulic pressure internally applied, followed by a low-temperature heat-treatment, the effective elastic limit may be raised. This auto-frettage process has been studied theoretically and practically. The theory and the mathematical calculations, as well as the experimental results on Ni, Ni Cr, and Ni Cr Mo gun steels, are given in great detail. The hydraulic apparatus used is described and the manufacture of 3 in. guns from monobloc forgings described clear through to the final firing tests.

Experiments were also made showing the applicability of the process to larger guns of built-up structure. A strain under load of 2½% was used, instead of 6% as in arsenals of some other countries, since in 2 particular cases studied the gain in safe pressure was only 5000 to 8000 lbs./in.^{2}

The report is written in a more or less chronological order with a vast deal of detail, so that much of it is in the nature of repetition, interspersed with mathematical calculations of what should happen according to theory in each experiment and experimental proof that it did so happen. Being apparently made up of a series of progress reports without a single clear summary, it is rather tedious reading, since the whole has to be read to follow the argument. It can be more readily followed if one first reads the briefer paper, "Effect of Cold Working on the Strength of Hollow Cylinders," by F. C. Langenberg, *Transactions American Society for Steel Treating*, Vol. 8, 1925, page 447.

The process is of such importance in the manufacture of guns, and can obviously be applied to pressure vessels, so that those who are interested will be grateful for the great amount of detail and be willing to spend the time necessary to follow the author's argument.

The method of making big guns by auto-frettage is so logical that all modern arsenals are doubtless about equally advanced in knowledge of the process, so that the publication probably does not give the arsenals of other nations anything they did not know already. The publication would be of more value to the non-military reader if it had been written from a more general point of view, even at the loss of some of the detail.—H. W. Gillett (12j)-B-

Calculation of the Rolls of Bending Machines. RÉNÉ TILKIN. *Iron Age*, Vol. 128, July 30, 1931, pages 315–318.

Object is to design rolls which will have the least deformation. Gives method of calculating rolls of bending machines, where these rolls are supported at the 2 ends and also at the center. Considers also deflection of the roll itself and effects of backing up. VSP(12j)

Cleaning (12k)

Cleaning of Metal. Pt. XI-XII. R. W. MITCHELL. *Metal Cleaning & Finishing*, Vol. 2, Nov. 1930, pages 935–945; Dec. 1930, pages 1025–1031.

Includes bibliography of 12 references. Compares the properties of various detergent materials, and discusses value of colloidal properties in a cleaning solution, optimum alkalinity range for fast cleaning, corrosion of metal being cleaned, temperatures, systems of cleaning, handling methods, choice of lubricants, and value of prompt cleaning. MS(12k)

The Bullard Dunn Process of Cleaning. FLOYD T. TAYLOR. *Metal Industry*, N. Y., Vol. 29, Sept. 1931, pages 394–395.

This process is carried out in a dilute solution of chlorides and sulphuric acid with Pb anodes and a current density of 60–77 amp./ft.^{2} Pb is plated out on the cleaned metal which is the cathode. PRK(12k)

Polishing & Grinding (12l)

Material Alone Is Not the Determining Factor in Selecting Grinding Wheel. A. ROUSSEAU. *Grits & Grinds*, Vol. 22, July 1931, pages 7–10.

It is pointed out that the selection of a grinding wheel has to be made according to the material to be ground, the nature of the work to be done and the physical properties of the material to be ground. The factors determining the characteristics of a wheel are the abrasive (aluminum oxide or silicon carbide), the grain size, the grade (resistance of abrasive grains to pulling out from the wheel), the structure (spacing of abrasive grains) and the bond. An example designates the manner of making a selection. Ha(12l)

Recent Developments in the Art of Roll Grinding. LLOYD A. PAINE. *Grits & Grinds*, Vol. 22, July 1931, pages 1–6.

After a discussion of the requirements of the surface of rolls, a grinder made of "Crystolon" abrasive by the Norton Co. is described. This grinder has sufficient cutting ability to remove stock up to 0.003 in. and can also be used to give a reflective finish with a hard, clean-bottomed surface. This combination reduces the grinding time to less than half. Ha(12l)

Grinding and Heat Treatment as a Cause of Cracks in Hardened Steels. C. E. SWEETSER. *Heat Treating & Forging*, Vol. 17, Aug. 1931, pages 776–780.

The effects of abusive heat treatment and abusive grinding are explained from tests made with a number of samples. See also *Metals & Alloys*, Vol. 2, Sept. 1930, page 738. Ha(12l)

Form Grinding in Successive Operations. WM. C. BETZ. *American Machinist*, Vol. 74, June 11, 1931, pages 901–902.

Ball Burnishing Hardware. F. M. BENWAY. *Metal Industry*, N. Y., Vol. 29, Oct. 1931, page 438.

High quality buffing is accomplished by rolling the pieces in barrels filled with special balls of various sizes. PRK(12l)

Metal Polishing by Flexible Polishing Wheels. EDWIN M. BAKER & GEORGE E. HOLBROOK. *Metal Industry*, N. Y., Vol. 29, Aug. 1931, pages 346–349; Sept. 1931, pages 388–389.

Paper presented before The Electrochemical Society, Apr. 23–25, 1931. Using a small polishing machine it was shown that: with coarse grain abrasive, increasing the pressure between steel being polished and wheel, the cutting speed is cut proportionally, but the efficiency is decreased, the optimum pressure being 0.5–1 kg./cm. width of wheel; with fine grain abrasive, increase in pressure above 0.5 kg./cm. width of wheel has little effect on cutting speed with but slight decrease in efficiency. Closely sized grain are much more efficient but have same cutting speed as loosely sized grain. Top dressing on wheels with fine grain reduces cutting speed but does not affect efficiency, whereas, with coarse grain, efficiency is increased with only moderate decrease in cutting speed. PRK(12l)

Metal Polishing. F. H. HOBBS. *Metal Industry*, N. Y., Vol. 29, Sept. 1931, page 393.

Practical observations on metal polishing are given. PRK(12l)

To Grind or Not to Grind. A. M. HAMMOND. *Modern Machine Shop*, Vol. 4, July 1931, pages 28–32.

The advantages over other finishing methods, for certain classes of work, of the face grinding machine are pointed out. First cost and up-keep may be frequently cheaper and a saving in material can often be effected. Ha(12l)

The First Institute for Grinding Technique in a German Technical University and the Application of Grinding in Industry and Commerce. (Das erste Institut für Schleiftechnik an einer deutschen Hochschule und die Anwendung des Schleifens in Industrie und Gewerbe.) MANGOLD. *Oberflächentechnik*, Vol. 7, Aug. 1930, pages 153–154.

The importance of exact grinding in obtaining the accuracy in machining required in modern industry is pointed out and the often neglected technique of grinding is discussed. The Technical University of Braunschweig was the first to install a chair for this branch of metal working. A brief discussion of the development and application of grinding technique, application of natural and artificial grinding materials and the grinding wheel for precision work follows. Ha(12l)

Ball Burnishing Small Parts. CARL F. WEBER. *Metal Cleaning & Finishing*, Vol. 2, Sept. 1930, pages 773–774.

In burnishing before Ni plating, parts are placed in a horizontal barrel, rotating at 30 r.p.m., with enough sawdust to clean and prevent scratching them. When clean, the parts are separated from the sawdust, immersed in a boiling commercial cleaning solution for 15 mins., and rinsed in cold running H_2O. They are then dipped in strong HCl for 5–10 mins. and rinsed again. They are next placed in the burnishing barrel with enough balls so that the contents come to within 4–6 ins. of the top of the barrel. About 200 lbs. of balls are used in a barrel 2 ft. deep by 11 ins. in diam. One-half gal. of soft soap is added and the barrel is filled with cold H_2O. The barrel is rotated for 1½–1¾ hr., after which, the contents are emptied into a sieve where the balls and parts are separate. The latter are rinsed, and then dried in sawdust. If they are to be plated immediately, they are cleaned and prepared for plating in the usual manner. After plating, the parts are immersed in a storage tank containing soap solution. In burnishing, the same procedure is followed as in burnishing before plating, except that the barrel is rotated for 40–60 mins. Balls and barrels should be cleaned with a solution of NaCN. MS(12l)

Keeping Qualities of Abrasives. HENRY R. POWER. *Metal Cleaning & Finishing*, Vol. 2, Dec. 1930, pages 1035–1037.

Common abrasives lose their capillarity value, when contaminated with moisture, oil, and dust, thus causing a reduction of the efficiency of the abrasive. A product has been developed which is no longer affected by absorption of moisture, so that ordinary storage can be used for this kind of abrasive. MS(12l)

Stresses and Cracks in Hardened and Ground Steel. GERALD R. BROPHY (General Electric Co.). *Transactions American Society for Steel Treating*, Vol. 18, 1930, pages 423–439.

Paper presented before the Twelfth Annual Convention of the Society, Chicago, September 1930. Includes discussion, 7 references to the literature and is illustrated by 39 photographs of ground surfaces. The author describes a method of detecting the location and intensity of stresses by acid etching. The larger the stresses the weaker the acid necessary to detect it. Moderate heating after quenching relieves quenching stresses and in like manner such heating after grinding relieves grinding stresses. Reheating of precision parts to 300° F. after a rough grind followed by a very careful finish is recommended. WLC(12l)

Increasing the Efficiency of Commercial Metal Polishing. E. M. BAKER & G. E. HOLBROOK. *Monthly Review American Electroplaters' Society*, Vol. 18, Apr. 1931, pages 22–32.

An experimental polishing arrangement is described with which the polishing process was to be investigated as to possibilities of higher efficiency because it had been found from the examination of the dust collected near a polishing wheel that about 50% of it was simply the same polishing grain thrown off from the wheel before it had done any work. Some of the conclusions of the experiments were that coarse grain (No. 46), doubling the pressure between wheel and steel being polished, will approximately double the quantity of steel polished away and quadruple the wheel wear per ft.^{2} of the steel polished. With fine grain (No. 150) the increase of pressure influences only slightly the quantity of polished-away steel and wheel wear. The use of polishing glue increases the wheel life for coarse grains, but not for finer grains. Closely sized grain is much more efficient than loosely sized grain. The characteristics of polishing glue, setting up polishing wheels, drying room conditions, the sizing of polishing grains are discussed. Ha(12l)

Selecting the Proper Buffing and Polishing Compound. P. W. ELLWANGER. *Metal Cleaning & Finishing*, Vol. 2, Nov. 1930, pages 955–956, 960.

General discussion of various factors influencing the selection of polishing and buffing compositions. MS(12l)

Tests for Determining the Temperature of the Surface of a Cut Section in Grinding Through Steel. (Versuche zur Ermittlung der Schnittflächentemperatur beim Durchschleifen von Stahl.) SILVIUS CRISAN. *Das Werkzeug* (supplement to *Maschinenkonstrukteur-Betriebstechnik*), Vol. 7, June 25, 1931, pages 133–135.

The grinding is done by means of slipping disks of 2.4–3.0 mm. thickness and 300 or 400 mm. diameter, at an average forward rate of 0.5 m./minute and a cutting rate (total velocity of the separate disks) of 80 m./second. It is thought that with this high rate of speed a sharp heating up of the cut surfaces will occur. This idea is refuted, however, by investigations which were carried out at the Institut für Werkzeugmaschinen-Untersuchungen and by the skillful methods of Dr.-Ing. E. Sachsenberg of the Technische Hochschule at Dresden. MAB(12l)

Influence of Handling on Abrasive Performance. TORREY ALLEN. *Metal Cleaning & Finishing*, Vol. 2, Sept. 1930, pages 769–770, 780.

Strength of the union that can be made between the abrasive and the glue depends upon the capillarity of the grains. Contamination by grease, moisture and dust lowers the capillarity value, thus decreasing the strength of the bond. Gives directions for applying abrasive to wheel. MS(12l)

Sand Blasting (12n)

Sand-Blast Abrasives. WILLIAM ASHCROFT. *Metallurgia*, Vol. 4, Aug. 1931, page 122.

Steel grit or shot has recently come into extensive use. The first cost of this material is higher than for sand, but the life is longer. Less dirt is formed with steel shot and the work has a cleaner surface. JLG(12n)

The Wear-Proof Sand Blast Nozzle. (Die verschleissfeste Sandstrahldüse.) U. LOHSE. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Aug. 29, 1931, pages 1107–1109.

After a short discussion of the action of a sand blast and costs for the compressed air, a new nozzle made by Badische Maschinenfabrik, Durlach, is described. This nozzle consists of several parts of steel, while the actual nozzle, through which the sand is blown, is made of tungsten carbide of a hardness 9.5–9.8. Comparison with an ordinary nozzle of a chill casting shows a life of 510 hrs. for the new against 4 hrs. of the old. Ha(12n)

Nozzle Dimensions and Most Advantageous Pressure of Sand Blast Blowers. (Düsenabmessungen und günstigster Arbeitsdruck von Sandstrahlgebläsen.) W. KAEMPFER. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Aug. 14, 1931, pages 653–656.

A number of diagrams show the interrelation of work required, number of nozzles, form of nozzles, length of jet for the 3 systems of sand movement by exhaustion, gravity and pressure. No general conclusions are given; the selection depends too much on the individual case. Ha(12n)

FOUNDRY PRACTICES & APPLIANCES (22)

On Low Carbon and High Silicon Semi-Steels. Masayasu Horikiri. *Proceedings of the World Engineering Congress*, Tokyo, 1929, Vol. 34, *Mining & Metallurgy*, Part 2, page 125.

The relation between the physical and mechanical properties and the melting conditions of cast iron melted in a cupola were investigated. It was found that in cast iron melted at a low temperature or rapidly melted at a high temperature, graphite arises in large flakes even with rapid cooling. On the contrary, when melted at a high temperature or slowly melted, fine graphite appears even with slow cooling. From these results, the author concluded that graphitization takes place independently of the rate of cooling. So, in order to produce a cast iron with uniform and excellent mechanical properties, low carbon and high silicon contents are desirable.

From these results the author proposed a theory of graphitization in foundry work: In cupola operations, some atomic carbon or its nucleus exists in the equilibrium such as $Fe_3C \rightleftarrows C + 3Fe$ in the melt, its amount depending upon the conditions in the molten state. The graphitisation depends on the distribution of the graphite nucleus before solidification. That is, in low temperature or rapid melting, graphite arises in large flakes, since much nucleus is present, but semi-steel containing less carbon is produced in high temperature and hence the fine graphite arises.

The author determined the compositions of low carbon and high silicon semi-steels having excellent mechanical properties and uniform structure, as follows: Total C 2.5 to 2.8%, Si 3.0 to 2.0%, Mn 1.0 to 2.0%, P and S a trace Those of such compositions were named "H Semi-Steels" by him. TS(22)

The Diagnostician in the Foundry. **(Der Diagnostiker in der Giesserei.)** H. Hertlein. *Giesserei mit Die Giesserei-Zeitung*, Vol. 18, Sept. 4, 1931, pages 715–716.

For economy in the foundry, the use of a diagnostician is recommended. This is an apparatus for recording periods of operation of machines; in this case, for molding machines for quantity production. It is illustrated as used in a certain molding process. Ha(22)

Molding of Some Oval Shapes by Template. **(Schablonieren ovaler Formen.)** K. Hoffmann. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Sept. 4, 1931, pages 710–712.

The usefulness of the elliptic compass in molding oval shapes is noted and a construction is described. Ha(22)

Advantages and Inconveniences of Different Methods for the Production of Cast Steel. **(Avantages et inconvénients des différents procédés employés a la fabrication de l'acier dans les fonderies d'acier.)** J. Deschamps. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 763–765.

Very brief generalities. HWG(22)

Description of the wax process as practiced up to the present day on the island of Java. HSvK(22)

Factors Influencing the Chilling Properties of Cast Iron. **(Les facteurs qui influencent les propriétés trempantes des fontes.)** A. L. Norbury. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 811–814. 5 figures.

General discussion of effect of superheating, repeated remelting and addition of steel, as means of dissolving the graphite, of effect of graphitizing elements and of rate of cooling. The article is less complete than other articles by Norbury that are in English. See also *Metals & Alloys*, Vol. 2, June 1931, page 122. HWG(22)

Effect of Excessive Atmospheric Moisture in Cupola Blast. Neil A. Moore. *Transactions & Bulletin American Foundrymen's Association*, Vol. 2, Sept. 1931, pages 275–296.

The relation of O content of the iron to the moisture in the cupola blast is discussed. No data is given, though the author believes the fluidity of cast iron is influenced by the O content of the iron; and that excessive atmospheric moisture in the blast increases the tendency of the cast iron to chill. See also *Metals & Alloys*, Vol. 2, Aug. 1931, page 150. CHL(22)

Iron and Steel Foundry Practice. Part VIII. Ben Shaw. *Metallurgia*, Vol. 4, Aug. 1931, pages 119–121.

Discussion of advantages and disadvantages of Bessemer, open-hearth and electric furnaces for making steel for casting. JLG(22)

Sands and Sand Testing. J. G. A. Skerl. *Foundry Trade Journal*, Vol. 45, July 23, 1931, pages 53–57, 58; Aug. 6, 1931, pages 86–90; *Metal Industry*, London, Vol. 38, June 26, 1931, pages 645–646.

A paper read before the Birmingham Convention of British Foundrymen, dealing with research work on raw molding sands typical of those in which 90% of iron and non-ferrous castings are made. A list of the experiments which have been carried out on each sand is given, as well as a description of methods and apparatus used for testing the mechanical constitution, strength, permeability and refractoriness of the sands. The author concludes: (1) Every sand has a definite moisture content at which it is strongest in the green-sand condition. This moisture content is not so great as that required to give the strongest sand after drying. (2) Molding sands are generally most permeable when they contain the moisture content at which they are strongest in the green condition. (3) Ramming increases strength and decreases permeability, while efficient milling increases strength but does not decrease permeability. (4) The permeability of a molding sand is largely governed by the silt content, the material coarser than the bonding material but less than the coarse sand grains. (5) The strength of a molding sand is increased about 20 times by drying. (6) The bonding material is the least refractory constituent of a molding sand, and, other things being equal, the greater the percentage of bonding material, the less refractory the sand. (7) Milling, among other considerations, improves the surface of castings. The paper is accompanied by 3 photographs and 3 diagrams. OWE(22)

The Brass Foundry in America. (La fonderie de laiton en Amerique.) W. Romanoff & C. O. Thieme. *Cuivre & Laiton*, Vol. 4, July 30, 1931, pages 332–334.

A general discussion of casting brass from new metals or from brass ingots. Tests of the mechanical properties did not show any deciding difference. This proved that the prejudice, frequently found against the ingot method, is not justified. Ha(22)

Method for Compacting Molding Sand in Molding Devices with Direct Action of Compressed Air on the Molding Materials. (Verfahren zum Verdichten von Formsand in Formeinrichtungen bei direkter Einwirkung von Pressluft auf die Formstoffe.) Friedr. Rolff. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Sept. 4, 1931, pages 712–714.

A few devices which constitute cheap and simple means for economical working are described. Core making and green core molding are especially considered. Ha(22)

Automatic Sand Plants. E. V. Ronceray. *Foundry Trade Journal*, Vol. 45, Aug. 27, 1931, pages 133–138.

A paper presented before the Lancashire branch of the Institute of British Foundrymen which deals with the problem of mechanizing foundries and the design of continuous-casting plants. The paper is accompanied by 17 illustrations of various devices which have been found of value in this connection and 3 diagrams showing the effects of milling on the different sand characteristics. Reference is made to various types of sand elevators, methods of preparing sand for the foundry, methods of removing sand from the storage bins, and arrangements for reconditioning sand for use in the foundry. A description is given of hopper- and conveyor-delivery systems. Space is devoted to the discussion of the paper. OWE(22)

Nickel Cast Iron. (Fontes au nickel, études et applications récentes.) F. Renaud. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 819–830. 9 figures; *Metallbörse*, Vol. 20, Aug. 23, 1930, page 1884.

A résumé. The information contained is taken largely from other publications especially those in English by Coyle, and from French publications by Ballay and others. HWG+WHB(22)

High Grade Light Metal Castings from Secondary or Virgin Metal? (Hochwertiger Leichtmetallguss aus Alt-oder Neumetall?) H. Röhrig. *Metallwirtschaft*, Vol. 10, July 17, 1931, pages 581–582; *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 3, July-Aug. 1931, pages 295–298.

Three lots of Al alloy remelt purchased from a first class dealer were analyzed and 3 lots of alloy were made up of virgin metals, containing the same percentage of Cu and Zn as the remelts, but less Si, Fe and other impurities. The 6 lots were cast into test bars in sand and chill molds. The yield point and Brinell hardness were almost the same, the tensile strength and elongation of the virgin metals were slightly better, and the impact strength and endurance limit were much better. Reasons given are the porosity of the remelt heats, the presence of the brittle, needle shaped constituent Al_3Fe and of oxides and nitrides, and a generally less uniform product. In spite of the improvement in the secondary metal situation, virgin metal should be used where high dynamic stresses are encountered CEM+Ha(22)

Contributions to the Knowledge of the Shaking Process. (Beitrage zur Kenntnis des Rüttelvorganges.) A. Rodeheuser & R. Walle. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, July 24, 1931, pages 593–596.

The conditions for compressing and tightening the sand in the mold are discussed and tests in the laboratory are described. These tests to elucidate the process were made under conditions closely approaching conditions in the foundry. Ha(22)

The Utilization of Brass Sheet-Cuttings and Chippings in the Foundry. (Die Verwertung von Messingblechabschnitten und -spähnen in der Giesserei.) E. T. Richards. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, July 10, 1931, pages 558–561.

The present great competition compels the utilization of a certain amount of scrap together with new metal. Considering that the brasses which are used commercially are usually standardized, the use of sheet cuttings is especially recommended as most economical. The preparation of the scrap for the foundry, drying, freeing of oil, briquetting, etc., is discussed. This preparation depends, to a certain extent, on the kind of furnace used for melting. Ha(22)

The Suitability of Different Oils as Core-Binding Material. (Ueber die Eignung verschiedener Oele als Kernbindemittel.) H. Nipper & K. Krekeler. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, May 1, 1931, pages 353–357.

Tests are described to determine the permeability, strength, structure of oil-sand cores as a function of the addition of oil, duration of baking and baking temperature and of humidity, and the influence which these factors have on the quality of the casting and its surface. Six different binding oils were used. Raw linseed oil has proved to be better than other binders recently developed. Ha(22)

Respiratory Protection in Foundries. (Atemschutz in Giesserein.) O. Neuss. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, May 29, 1931, page 442.

A few protective devices (masks) against carbon monoxide, Pb and Zn vapors are described. Ha(22)

FURNACES & FUELS (23)

Investigations of the Combustion in Industrial Furnaces. **(Untersuchungen zur Kenntnis der Verbrennungs vorgänge in technischen Gasfeuerungen.)** R. Pistor. *Archiv für Eisenhüttenwesen*, Vol. 4, June 1931, pages 565–577.

Report 151 of the Committee on Heat of the Verein deutscher Eisenhüttenleute. Includes discussion. In burning coke oven gas with deficient air supply, the composition of the unburnt waste gases varies with the amount of air deficiency. With deficient air supply, the H content of the waste gases surpasses that of the coke oven gas, but decreases with increasing air. The content of CO reaches a maximum at half the theoretical air volume. The amount of H of the flame and of the waste gases is practically the same. The intimate mixture of gas and air and the air volume determine the length of the flame. A formula is developed to calculate the theoretical combustion temperature. GN(23)

Powdered Coal in Steel Forging Plants. Wm. Clifford Rehfuss. *Heat Treating & Forging*, Vol. 16, Nov. 1930, pages 1447–1449, 1451.

A general discussion of powdered coal systems and the burning arrangements in furnaces. A particular example is described. Ha(23)

The Gas Producer. III. Conduction of Gas Producers Fuel Tests. John W. Romig. *American Gas Journal*, Vol. 134, Jan. 1931, pages 54–55.

Describes the Orsat apparatus and tells how the following solutions are made for the apparatus: ammoniacal cuprous chloride solution, potassium hydrate solution, potassium pyrogallate solution, waste gas and producer gas. MAB(23)

Industrial Electric Heating. XVI. Heating and Cooling of Metals. N. R. Stansel (General Electric Co.) & S. L. Hoyt (A. O. Smith Corp.). *General Electric Review*, Vol. 34, Oct. 1931, pages 573–579.

This installment deals with the basic property of allotropic transformation in consideration of the relations of the engineering properties of metals. When a C-steel is heated through its critical range, 2 changes taking place are: (1) the body-centered cubic lattice is transformed and (2) C forms a solid solution (austenite) with γ iron by inclusion of the C in the space lattice of the γ iron crystalline structure. 3 purposes of such heating are: (a) strain relief, (b) diffusion of the C through the mass of the metal, and (c) recrystallation, i. e., grain refinement. The cooling of C-, eutectoid- and hypereutectoid steels is discussed. Numerous curves and photomicrographs are shown. WHB(23)

Powdered Coal in German Malleable Foundries. **(L'emploi du charbon pulvérisé dans les fonderies Allemandes de malléable.)** R. Stotz. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 889–902. 32 figures.

The Brackelsberg rotating, and the Wirges oscillating furnaces are described and illustrated, as are reverberatory type furnaces, all fired with powdered coal. Annealing furnaces similarly fired are also described. The pulverizing equipment and the burners are shown. Considerable economic advantage is claimed for all these. Use of the Brackelsberg furnace is increasing. It gives malleable averaging 63,000 lbs./in.^{2} tensile strength, 19% elongation in $2^1/_2$ in. HWG(23)

Water Cooled Skids in Rolling Mill Furnaces. **(Wassergekühlte Gleitschienen und Stützen in Stossögen.)** A. Sprenger. *Stahl und Eisen*, Vol. 51, July 30, 1931, pages 961–965.

The article describes new constructions and arrangements of water cooled skids of rolling mill furnaces that offer remarkable advantages in comparison with previous types of water cooled skids. GN(23)

Electric Annealing Furnaces in the Metal-Working Industries. **(Elektrische Glühöfen in der metallverarbeitenden Industrie.)** Alf. Schau. *Siemens-Zeitschrift*, Vol. 11, Apr. 1931, pages 209–218.

The advantages of electrically (resistance) heated annealing furnaces, as shown by several examples, are discussed. The principal requirement of a furnace is that it must be so constructed, charged or controlled that in all sections of the furnace the difference between heat supplied, and externally and internally absorbed, is as equal as possible. If this condition is fulfilled, electric heating facilitates greater uniformity of temperature than any other heating method. Examples given are a soaking pit for ingots up to 20 t. heated by a 3-phase 500 volt current, 350 K.W consumption; several furnaces for small parts, 1000° C., 250 to 350 K.Wh/t. consumption; for refining of steel, wheel tires for railroad cars, annealing of sheets, 140 K.W; hardening furnace for sickles, 800° to 900° C., 70 K.W; bare annealing of copper wire with water vapor as protective atmosphere, daily output of 15 to 20 t. of wire, 60 K.W. Ha(23)

Modern Gas Producer Practice. F. Johnstone Taylor. *Iron & Steel Industry & British Foundryman*, Vol. 4, Mar. 1931, pages 191–193; Apr. 1931, pages 239–244; June 1931, pages 302–304; July 1931, pages 339–342; Aug. 1931, pages 371–374; Sept. 1931, pages 405–406, 409.

A comprehensive survey of the present position in regard to gas producer practice. The characteristics of various types of producers and accessory equipment are described in detail. The uses and production of producer gas are dealt with briefly. CHL(23)

Heat Balance for Rotary Forging Furnaces. Theo. F. Schilling. *Heat Treating & Forging*, Vol. 16, Oct. 1930, pages 1317–1318, 1321; Nov. 1930, pages 1452–1454.

See *Metals & Alloys*, Vol. 2, Feb. 1931, page 49. Ha(23)

Annealing Copper and Its Alloys in Electric Furnaces. **(Elektrisches Glühen von Kupfer und seinen Legierungen.)** E. Fr. Russ. *Metallwirtschaft*, Vol. 10, June 19, 1931, pages 495–500; June 26, 1931, pages 513–518.

The comparative efficiency of coke, gas and electric furnaces is compared. A table shows the K.W. hours required to heat various metals to various temperatures. Heating units of Cr-Ni-Fe alloys are used in electric furnaces. Their advantages include absence of products of combustion, almost neutral atmosphere, easy temperature control and uniform heating. They can be placed in the shop wherever needed. Different types are (1) Muffle furnaces, for sheets, wire and billets. There is a loss of heat at the door in this type. (2) Long annealing furnaces, for bars, tubes and shapes loaded on buggies. (3) Continuous billet furnaces for bolts and billets of brass, Cu and nickel silver, with horizontal or inclined bottoms. The charge is pushed through by hand. Side doors are sometimes used to prevent heat loss. (4) Conveyor furnaces, for coiled strip. Good heat control resulting in close control of hardness and grain size is obtained in this type and the operating cost is low. Examples including dimensions and construction details and current consumption are given. A strip annealing furnace can be combined with a quenching tank, acid dip, rinsing tank, drying oven and coiling device, all using the same continuous conveyor. (5) Rotary furnaces, for small parts, consisting of a drum rotating on rollers or a circular furnace, the hearth of which rotates on rollers. (6) Bright annealing furnaces, air tight pot furnaces with a double top for a seal. The air in the pot is displaced by a neutral gas to prevent oxidation of the charge and the charge must be left in the furnace after annealing until cool. Large charges are desirable. CEM(23)

The Design and Operation of Open-Hearth Furnaces. Part II. C. W. Veach (The Bettendorf Co.). *Rolling Mill Journal*, Vol. 5, Feb. 1930, pages 91–94, 106.

Describes design and construction of the various parts of the open-hearth furnace and discusses the engineering principles concerned in the design of foundations, insulation, walls and roof with methods for meeting exacting conditions of service. JN(23)

Development of Steel Mill Furnaces with Remote Gas Supply. **(Entwicklung der Feuerungen in Eisenwerken unter den Einfluss der Ferngasversorgung.)** P. Rheinländer. *Archiv für Eisenhüttenwesen*, Vol. 4, May 1931, pages 513–531; *Stahl und Eisen*, Vol. 51, June 18, 1931, pages 767–769.

Report No. 150 of the Wärmestelle of the Verein deutscher Eisenhüttenleute. Construction, capacity and operation of a great variety of steel mill furnaces with remote gas supply are described; the results of tests are tabulated. It must be decided, in every individual case, if the rebuilding of furnaces for remote gas supply or the new construction of furnaces with remote gas supply is economical. The introduction of gas in forging plants offers great advantages for heat efficiency, since the use of gas is especially applicable to furnaces with high temperatures. Due consideration must be given in this case to the scaling proposition. The increased scaling in gas fired forging furnaces retarded the introduction of such furnaces. It can, however, be stated that proper design and control of such furnaces keeps the scaling within reasonable limits. The type of scale varies with the furnace atmosphere, whether ordinary or reducing. A neutral or slightly oxidizing atmosphere seems to be more favorable. In introducing gas heating in annealing furnaces, the temperature control is of particular importance. Three different types of temperature controllers are described. The largest part of the paper deals with the efficiency of heating with coal gas supply. Though it is found in comparing the cost of the heat unit of various fuels, that the cost of coke oven gas is relatively high, it shows the lowest heat loss by waste gases. Under certain conditions of fuel price, heat value and air excess, diagrams of degree of efficiency, cost of heat unit and quantity of fuel are designated per 1 m.^{3} of dried gas. The following table shows the difference of efficiency:

Type of fuel	Lower heat value kg./cal.	Air excess	Efficiency
Coke oven gas	4000 kgcal./m.^{3}	10%	53%
Oil	9500 kgcal./kg.	20%	53%
Producer gas	1300 kgcal./m.^{3}	10%	42%
Coal	7000 kgcal./kg.	70%	34%

In comparing the cost of 1000 heat units utilised in the furnace, the heat in coke oven gas is more expensive at low temperatures than in the case of coal or producer gas. At high temperatures, the economy is reversed. The higher capacity per unit of area and the easier control of the gas fired furnace offers a further saving of heat. Furthermore, the advantages of operation of gas fired furnaces are pointed out. Numerous calculations of economy for various mill furnaces are included in the paper. GN(23)

Principles and Some Practical Applications of Electric Furnaces with Atmospheric Control. A. N. Otis (General Electric Co.). *Iron & Steel Engineer*, Vol. 8, Aug. 1931, pages 352–359.

Includes discussion. Methods of obtaining low cost H for furnace atmospheres are discussed. If comparatively large amounts are wanted, the "Electrolene" producer offers the cheapest means of obtaining a gas high in H content. Electrolene consists of about 75% H_2 and 20% CO and is obtained by cracking any available hydrocarbon gas in the presence of steam. Dissociated ammonia is also a convenient and relatively inexpensive source of H. For bright annealing, the gases used must be purified from all traces of O, water vapor and S. Several types of hood, pit, tunnel and elevator furnaces for bright annealing and copper brasing are illustrated and discussed. Considerable saving in time and cost of heating are realized with electric furnaces for strip annealing as compared with the old methods. WHK(23)

Soaking Pits Operate without Checkers. J. B. Nealey. *Steel*, Vol. 89, Aug. 27, 1931, pages 31–32.

Describes a new type of soaking pit in which the checkers have been replaced by refractory tile recuperators or metallic air preheaters. The intermittent reversal of firing and draft has been supplanted by the one-way system in which the gases are fired continuously through a port at the top of the pit and taken out continuously at the bottom of the pit in the same wall with the firing port. Gas is used as fuel and hot air from the recuperator is supplied to the burner. The temperature of the soaking pit is maintained at from 2300° to 2400° F. by the waste gases which leave the pit at about 2200° F. Ha(23)

A Study of the Influence of Certain Physical and Chemical Factors on the Operation of the Blast Furnace. **(Étude de l'Influence de Certains Facteurs Physiques et Chimique sur la March des Hauts Fourneaux.)** Armand Peters. *Chimie et Industrie*, Vol. 25, June 1931, pages 1327–1338.

The author shows how the consumption of coke may be decreased by increasing the indirect reduction. The action of the gas from the blast furnace on the oxides of Fe is discussed, as well as the agents which favor indirect reduction, the combustion which takes place in the crucible, and the amount of coke used (in lbs.). MAB(23)

The Propagation of Combustion in Powdered Coal. H. E. Newall & F. S. Sinnatt. *Great Britain Safety in Mines Research Board Paper* No. 63, 1930, 58 pages.

The influence of preoxidation of the coal on the time of propagation was examined by heating the coal for certain periods of time in air at the temperatures of 100°, 150° and 200° C. This treatment caused an increase in the time required for the zone of combustion to travel through a definite length of a train of the dust. The increase in time was marked in the early stages of oxidation. Finally a state of oxidation was reached when the combustion could no longer be initiated in the coal. Different coals showed marked differences as regards the increase in time and in the duration of oxidation required to bring about cessation of propagation. The effect on preheating the coal in nitrogen has been studied and it was found that preheating at temperatures from 100° to 300° C. increases the time of propagation. From 300° to 400° C., the time decreases initially, but prolonged heating in N causes an increase in the time of combustion. An increase in the O percentage above that of normal air decreased the time, and a reduction of the O percentage caused an increase in the time of propagation. There was, however, no exact relationship between the O content and the rate of combustion. The lowest percentage of O in the atmosphere in which the coal would burn varied with different coals, but the minimum recorded was 14.0%. The addition of small amounts of inorganic substances in the majority of cases decreased the time of propagation. Potassium and sodium salts, particularly the hydroxides, were effective in decreasing the time, the carbonates and iron salts acted in a lesser degree. Ammonium chloride and hydrochloric and sulphuric acids increased the time of propagation. It was observed that hydrogen cyanide was one of the gaseous products of combustion and a brief study was made of the conditions under which it is produced during the propagation of a zone of combustion. The temperature attained in the center of a cone of coal during combustion was controlled by varing the rate of excess air to the coal and the amount of hydrogen cyanide produced at various temperatures was determined. The maximum amount which could be obtained was 0.1% by weight of the coal. No hydrogen cyanide was found at temperatures lower than 300° C., and in certain coals only a trace was present when temperatures of 450° to 480° C. were reached. The experiments show that the composition of the oxidation product produced from any coal is constant and independent of the rate of propagation of the zone of combustion through the coal. WAT(23)

REFRACTORIES & FURNACE MATERIALS (24)

The Passage of Gas Through the Walls of Pyrometer Protection Tubes at High Temperatures. WM. F. ROESER. *Bureau of Standards Journal of Research*, Vol. 7, Sept. 1931, pages 485–494; *Bureau of Standards Research Paper* No. 354.

The results of the measurements of the rate of passage of air through 36 tubes of refractory porcelain, both glazed and unglazed, (11 different classes) 2 of fused silica, 1 of pyrex glass, 2 of alundum and 15 of metal are given for various temperatures which the tubes would withstand without noticeable deformation. The tests indicate that the very refractory porcelain tubes (often referred to as sillimanite or mullite) are decidedly superior to the older porcelain tubes, both in refractoriness and gas tightness. The results indicate that tubes of calorized wrought iron are more gas tight than those of other metals at the higher temperatures. Nickel-chromium tubes, in general, were more gas tight than those of other alloys. The tests also showed that it was possible to maintain pressures of less than 0.001 mm. of Hg in a refractory porcelain tube at 1400° C. by the use of an ordinary laboratory type mercury vapor pump. Methods of testing are described and a very brief discussion given of the processes by which air may pass through the tube walls. No attempt has been made to correlate the data reported in this paper with data obtained by other observers, since measurements have not been made under similar conditions. Most of the data reported have been on the passage of gases through glass, silica and metals. No data have been found on the passage of air through solids or on the passages of gases through porcelain. WAT(24)

Some of the Newer Uses for Silicon Carbide. CHARLES MCMULLEN. *Metal Industry*, London, Vol. 39, July 10, 1931, pages 35–36.

Besides being used as an abrasive, silicon carbide finds use as a refractory and as resistance for heating elements in electric furnaces and therapeutic lamps, resistance in radio circuits and even as lightning arrestor for it becomes a conductor at high voltages. See *Metals & Alloys*, Vol. 2, Aug. 1931, page 152. PRK(24)

Recuperator Theory. (Contribution a la théorie des récupérateurs alternatifs.) L. THIBAUDIER. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 73–86.

Mathematical. Includes discussion. HWG(24)

The Behavior of Refractory Linings in Furnaces of the Iron and Metal Foundry. (Ueber das Verhalten feuerfester Ausmauerungen in Oefen der Eisen- und Metallgiesserei.) F. NIEBLING. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Feb. 13, 1931, pages 144–146.

A discussion of the properties of a refractory material shows that the suitability of a brick cannot be judged on the basis of any one individual test. The mutual relations between change of temperature and attack of slag, and between high temperatures and temperature change are of much greater importance. These relations cannot easily be determined by a single test. Many failures can be traced to insufficient consideration of these relations. Ha(24)

The Possibility of Andalusite as a Refractory. FRANK H. RIDDLE. *Metal Industry*, London, Vol. 38, June 5, 1931, pages 571–572.

Paper presented before the Electrochemical Society at Birmingham, Ala., Apr. 1931. See *Metals & Alloys*, Vol. 2, Sept. 1931, page 190. PRK(24)

Sillimanite Minerals as Refractories. F. H. RIDDLE. *Brick & Clay Record*, Vol. 79, Aug. 11, 1931, pages 130, 132, 134, 138.

This paper gives a review of the recent development of natural and synthetic refractories and the tests made with them. The natural deposits, process of preparation, bonding materials and tests made are described. Seven references are cited. Ha(24)

Refractories and Their Uses. P. F. THOMPSON (University of Melbourne). *Chemical Engineering & Mining Review*, Vol. 23, Sept. 5, 1931, pages 455–459.

An abstract. Refractories are discussed from the standpoints of: changes undergone during heating alone, reactions between grains and bond during heating, changes on cooling, reactions with substances being treated and testing of them. WHB(24)

Electric Furnace Production of High-Heat-Duty Refractories. FRED W. SCHROEDER (Corhart Refractories Company). *Industrial & Engineering Chemistry*, Vol. 23, Feb. 1931, pages 124–126.

Herein are described the making of molds, preparation of the batch, melting, casting and annealing, properties and uses of refractories. Blocks as large as 18 × 18 × 48 ins. can be cast satisfactorily. Electric furnace refractories find application also in metallurgical equipment such as forging furnaces. MEH(24)

GASES IN METALS (25)

Melting and Solidification Points of Silver Copper Alloys Containing Oxygen. (Über Schmelz- und Erstarrungs-vorgänge sauerstoffhaltiger Silber-Kupferlegierungen.) H. MOSER & K. W. FRÖHLICH. *Metallwirtschaft*, Vol. 10, July 3, 1931, pages 533–535.

Contains 8 references. Ag-Cu alloys used for silverware easily absorb O with the formation of Cu_2O when molten which is objectionable in later rolling, forging and polishing operations. The system Ag-Cu-Cu_2O was investigated thermally and microscopically. The alloys were melted under N in hard porcelain crucibles and heated to 1240° to insure equilibrium. Preliminary tests showed that Cu_2O was soluble in a 1:1 Ag-Cu alloy at its melting point up to at least 27%. With 1% Cu_2O the melting point of Ag-Cu alloys is raised. The maximum increase is 43–48° at 80% Ag, 850° against 802–807°. Ag, Cu and Cu_2O each form a binary eutectic with the other. The ternary eutectic was found to contain 0.7–0.8% Cu_2O, 66.5% Ag and 32.8% Cu with a melting point of 776°. The binary eutectic contains 71.6% Ag and 28.4% Cu and melts at 779°. If a small amount of Cu_2O is added to this binary eutectic considerable quantities of primary Ag separate on cooling. If Cu_2O in the ternary eutectic is replaced by Cu, Cu separates. This is illustrated with photomicrographs and cooling curves. In the eutectic Cu_2O is present in the form of small rounded granules, but if an excess is present it segregates into long dendrites. CEM(25)

Gray Iron and Other Metals Are Affected by Gas. E. PIWOWARSKY. *Foundry*, Vol. 59, Aug. 15, 1931, pages 48–50, 53–54.

Metals and alloys take up certain gases in liquid and also in solid states. According to Sieverts, the solubility, m, of H in Fe in relation to pressure (p in atmospheres) by the constant temperature, the relationship: $m = c\sqrt{p}$ where c is a constant. Hydrides of Fe have not been confirmed metallographically but nitrides of Fe and accompanying elements have been observed many times. O is present in liquid Fe often as FeO or combined with other elements found with Fe. CO and CO_2, which escape during solidification and which are the cause of porosity and blow-holes, owe their origin to reaction between the metallic oxides present and the C. Deoxidation with C in vacuum leads to complete removal of O. Complete deoxidation is not possible as long as slag exhibits free and dissolved oxides. Cast Fe melted hot always requires end treatment with Si, Al, Ti or V to obtain dense castings free from blow-holes. Contains several graphs and tables. VSP(25)

The Influence of Oxygen on the Working of Technical Silver Copper Alloys. (Der Einfluss des Sauerstoffs auf die Verarbeitbarkeit der technischen Silber-Kupfer-Legierungen.) E. RAUB. *Metallwirtschaft*, Vol. 10, Oct. 2, 1931, pages 769–773.

Seven references. Cu_2O is detrimental to Ag-Cu alloys because it coalesces readily and is very hard and brittle. The hardness makes working more difficult as Cu_2O will not flow. During forging the cast bars are brittle and crack if they contain Cu_2O, which sometimes forms dendrites. During rolling, sheets are apt to crack on the surface. Microscopic examination of such cases nearly always disclose large Cu_2O inclusions adjacent to the cracks and often also finely divided CuO. Even the 80% Ag alloy will be covered with a thin oxide coating if annealed in air. If this coating is not removed by an acid dip it is rolled into the soft metal where it coalesces into larger particles, which may cause a spalling off at the surface. It the annealing and rolling process is repeated, several layers of Cu_2O may form on top of each other. Surface irregularities after the polishing are caused by Cu_2O inclusions near the surface on account of their higher hardness. They also prevent uniform electroplating. Porous spots form over the oxides which retain a trace of the plating solution and later corrode. O may be introduced into the alloy at various stages. Some is contained in the original Cu used, especially if it is in the form of shot or granulated. Much of the raw material is scrap. In England and the U. S., Cd is used as a deoxidizer during the melting; in Germany, 10% phosphor Cu. Phosphor Cu reacts more intensively than Cd but causes defective silver plating if used in excess. Addition of 0.05% to secondary material is sufficient. Various fluxes or charcoal are used for protection against air during melting. During casting a reducing atmosphere can be produced around the metal stream by a piece of burning wood. To prevent absorption of O during annealing, the alloy can be annealed in H or illuminating gas, but only if it is free from oxide to start with; otherwise steam pockets will be formed by the reducing action of H. After annealing, surface oxidation should be removed by an acid dip. CEM(25)

EFFECTS OF ELEMENTS ON METALS & ALLOYS (27)

Iron Reduces Crystal Size in Aluminum Bronze. CHARLES VICKERS. *Foundry*, Vol. 59, May 1, 1931, pages 55–57.

Al bronze differs from other metals having large crystals in that it is not weak and easily broken. Temperature will weaken bond between these crystals and when proper degree is reached they will drop apart. Bronze cylinder 8 in. high, 6 in. in diameter having risers of same weight cast in sand showed Brinell hardness of 94. It contained 10.03% Al, 0.007% Ca and the rest Cu. Physical properties ranged from 50,000 to 65,000 lbs./in.^{2} with elongation of 7 to 20%. Considers self annealing. Discusses experiments of Portevin and Amon on heat treatment of Al bronze. Quenching from 1652° F. and reheating around 1260° F. increases tensile strength. Presence of Al with Cu and Fe will insure a perfect triple alloy. Tabulates results. VSP(27)

The Influence of Alloy Elements on the Iron Carbide of Cast Iron. (Der Einfluss der Legierungselemente auf das Eisenkarbid des Gusseisens.) FRANZ ROLL. *Giesserei*, Vol. 16, Oct. 4, 1929, pages 933–936.

A recent contribution to the literature of alloy cast iron approaches the subject from the purely theoretical standpoint and deals with the influence of the various alloy constituents as related to the position of these elements in the periodic system. The groups of the system are individually considered and the influence which the respective elements may be expected to exert on the carbide constituent of the iron is discussed. (27)

The Influence of the Elements Silicon, Phosphorus, Aluminum, Nickel and Chromium on the Quasi-Isotropy and the Wall Thickness Sensitivity of Cast Iron. (Ueber den Einfluss der Elemente Silizium, Phosphor, Aluminium, Nickel und Chrom auf die Quasiisotropie und die Wandstärkenempfindlichkeit von Gusseisen.) E. PIWOWARSKY & E. SOEHNCHEN. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, July 3, 1931, pages 533–537.

The crystalline state is characterized by its anisotropic character; that is, the properties of the crystals are different in different directions. The individual crystals making up a material are so numerous that the single crystal is very small in relation to the wall thickness and the body will, therefore, behave like an isotropic body. This shows the same properties in all directions because the properties of the single crystal are of no import. This state is designated as quasi-isotropy. The quasi-isotropy is the necessary condition for the mechanical uniformity of a body. The thickness plays, therefore, a very important part and the present investigation shows that Si and P deteriorate the quasi-isotropy and wall thickness sensitivity considerably. Al has the same effect, although milder. Ni acts very favorably on both factors and Cr has no marked influence. The respective tests are reproduced in full and 13 references are cited. Ha(27)

Some Effects of Nickel on Bronze Foundry Mixtures. N. B. PILLING & T. E. KIHLGREN. *Transactions & Bulletin American Foundrymen's Association*, Vol. 2, July 1931, pages 93–114.

Foundry bronze mixtures as modified by contents of Ni up to 3% are discussed. Small amounts of Ni were found to be favorable. The best Ni content differs considerably depending upon the nature of the base mixture. CHL(27)

Factors Influencing the Hardness of Cast Iron. (Ueber die Faktoren die Härteeigenschaften des Gusseisens beeinflussen.) A. L. NORBURY. *Metallbörse*, Vol. 20, Aug. 30, 1930, pages 1939–1940.

The influence of various factors upon the precipitation of fine graphite particles in the molten Fe is discussed. The addition of graphitizing substances probably causes the precipitation of a large number of finely divided graphite particles which are dissolved easier and quicker than the big flakes. Gray castings made with the addition of such graphitizing substances show better strength values. Fe-Si, Ca-Si or Ni additions have this effect. Mn and S by themselves favor the tendency toward hardening. Always being present at the same time, however, they neutralize each other through the formation of MnS. In order to neutralize the effect of S, an excess of 0.3% Mn over the quantity theoretically required for the formation of MnS, is necessary. P seems to diminish the tendency toward hardening of thin pieces cast in sand molds. The tendency toward hardening is diminished by Al, Ni, Cu and Co, while it is increased by V, Cr, Si, Mo, Sn, Sb and W. WHB(27)

Vanadium in Metallurgy. (Le Vanadium en sidérugie.) N. PETINOT. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 103–115.

General discussion of vanadium steels. In discussion, Houdremont gives a table showing the benefit of high quenching temperature in the heat-treatment of vanadium steels as far as tensile strength goes, but with loss of impact resistance. He states that except in high speed steel and as a deoxidizer, other elements, especially Mo, nowadays replace V. He particularly mentions high-temperature service. Petinot replied that the V steels cited by Houdremont with 0.05 and 0.45% V were not representative of normal V steels and gives a table showing high impact after a high-temperature quench and a draw of a 0.15% V, CrV steel, also one showing only slightly greater ductility for Cr-Mo than for Cr-V steel heat-treated to the same tensile strength. HWG(27)

Steels Made without Manganese. S. B. Ritchie. *Metal Progress*, Vol. 20, Sept. 1931, pages 35–39, 118.

A paper presented before the Boston Convention of the American Society for Steel Treating, Sept. 1931 and to be published later in greater detail and with discussion in the Transactions. The strategic character of Mn as a material not produced in this country has encouraged the Ordnance Department to make studies of steel produced without Mn. Melts are described using Zr instead of Mn as a deoxidizer. The melting was done in a high frequency induction furnace and all the charge with half of the Zr was added at the start. The charge consisted of an Armco iron base to eliminate the introduction of Mn. The other half of the Zr was added 10 minutes before tapping. Steel made was a forging grade of V-Mo steel. Macro-etched sections of ingots, forgings and centrifugal castings made from these heats are shown. The study of the heat treatment and physical properties of the steel without Mn shows it to be equal in quality and properties with alloy steels of the same alloy content with normal Mn. WLC(27)

INSTRUMENTS & CONTROLLERS (28)

A New Temperature-Time Regulator. (Ein neuer Temperatur-Zeit-Regler.) G. Gerold. *Stahl und Eisen*, Vol. 51, May 21, 1931, pages 650–651.

Brief description and practical results of a new Siemens & Halske temperature controller which is distinguished by its strictly automatic control. Any desired temperature-time course can be obtained. GN(28)

Automatic Controls in the Chemical Industry. W. N. Greer. *Canadian Chemistry & Metallurgy*, Vol. 15, Sept. 1931, pages 239–240, 245.

Electrolytic conductivity and H-ion concentration are finding increasing usage in the chemical industry for automatic control. Applications in the control of pickling baths, and of black liquor diffuser washings are discussed. In pickling baths, a conductivity measurement alone cannot be used for automatically controlling the acid concentration. If the bath is made continuous by overflow with continuous addition of water and the H_2SO_4 addition controlled, the problem is simplified. The bridge circuit employed for the measurement of and contacts for actuating the control are illustrated. In automatic H-ion concentration control, a quinhydrone-calomel electrode designed for continuous measurements is used as the detecting unit. An electrode is illustrated, applicable where 100 cc./min. continuous sample of solution is available and the pH range is 1–9, the temperature range 5–40° C., and the solution practically free from oxidizing or reducing substances and suspended materials. WHB(28)

Air-Flow Gauge and Calculator. A. Baumann. *Brown Boveri Review*, Vol. 18, Feb. 1931, pages 109–110.

The apparatus described is used to calculate the flow of steam and compressed air produced in electrical energy, gas and water plants. The air meter, for a blast furnace blower records the weight of dry air independently of the air pressure, temperature or humidity. MAB(28)

Practical Evaluation of the Calibration Curves for Thermo-elements. (Praktische Auswertung von Eichkurven für Thermoelemente.) W. Koch. *Forschung auf dem Gebiete des Ingenieurwesens*, Vol. 2, Aug. 1931, pages 302–304.

Explains a simple and accurate method for determining calibration curves thermoelements. The accuracy of the method is considered. MAB(28)

The Capacities of Emission of Liquid Iron Alloys. (Die Emissionsvermögen von flüssigen Eisenlegierungen.) G. Naeser. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 12, No. 23, 1930, *Report* No. 168, pages 365–372; *Stahl und Eisen*, Vol. 51, Mar. 5, 1931, page 304.

The coefficients of emission of liquid iron alloys were determined between 1350° and 1550° C. Beside the red color generally used, measurements were also taken in yellow and green in order to find out the color that has the smallest deviation from the true temperature. The measurements were taken in a high frequency furnace. The C content does not affect the coefficients of emission. The deviations from the true temperatures are smaller in the green than in the red. The results of the measurements in red are in satisfactory accord with previous investigations. GN(28)

Dust-Concentration Meter for Blast-Furnace Gas. A. W. Simon. *Iron & Coal Trade Review*, Vol. 122, Jan. 2, 1931, page 7.

The construction of an instantaneous and recording dust-concentration meter, a so-called kapnograph, is described which is based on the principle that the amount of light absorbed and, therefore, transmitted by a column of dust-laden gas depended on the dust content of the gas. The light of a lamp is concentrated and sent through the column and thrown onto a light sensitive thermopile which is connected to a recording meter. Ha(28)

Remote Measuring in Steel Mills. Part I. The Principles of the Methods of Remote Measuring. (Fernmessen auf Eisenhüttenwerken. I. Die Grundzüge der Fernmessverfahren.) B. von Sothen. *Archiv für Eisenhüttenwesen*, Vol. 5, July 1931, pages 17–28.

The paper deals with the principles and methods of remote measuring devices for the manifold applications in steel mills. GN(28)

On a Comparameter for Determination of Thermal Expansion of Solid Bodies up to 1400° C. (Ueber einen Komparator für Ausdehnungsmessungen fester Körper bis zu 1400° C.) W. M. Cohn. *Zeitschrift für Instrumentenkunde*, Vol. 50, Mar. 1930, pages 198–204, 10 ref.

After characterizing the former comparators of the Physikalisch-Technische Reichsanstalt and of the Bureau of Standards, the author introduces the new instrument by which determination as high as 1400° C. can be achieved. EF(28)

Instruments and Measurements. Annual Report of Committee on Instruments and Measurements. E. J. Rutan, *et al.* *Electrical Engineering*, Vol. 50, July 1931, pages 587–589.

Activity has been shown by the Committee on standard definition for telemetering, standards for recording and indicating instruments, a revision of Standards No. 14—instrument transformers, a revision of electric units, a symposium on precision measurements, technique of temperature measurements, measurement of reactive power, and a method of measuring distortion factor. Calibration of Beckmann Thermometer. I. Corrected Eucken's Method. Mototaro Matsui, Shuu Kambara, Katsuji Miyamura & Akira Miyoshi. **II. Precise Calibration of Graduation Scale.** Mototaro Matsui & Katsuji Miyamura. *Journal Society of Chemical Industry*, Japan, Vol. 34, June 1931, pages 197B–202B.

The corrections and improvements to Eucken's method of the operation of the calibrations were made on the following two Beckmann thermometers: (1) Jena glass 16III Rober Carl No. 19510, P.T.R. No. 100862 certified in 1923, (2) Jena glass 16III V. F. L. Berlin No. 99,832. Part 2. Precise calibration of graduation scales was performed on the same instruments as used in Part I. The Gay-Lussac method and the Neumann-Theisen method were used. A correction table of graduation scale is given. MAB(28)

Some Sources of Errors in Thermo-Electric Measurements. (Einige Fehlerquellen bei thermo-elektrischen Messungen). O. Walger & F. R. Lorenz. *Zeitschrift für technische Physik*, Vol. 11, July 1930, pages 242–246.

The paper pertains to the influence of the microstructure of lead wires upon the accuracy of thermo-electric measurements. EF(28)

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

The abstracts appearing under this heading are prepared in coöperation with the Joint High Temperature Committee of the American Society of Mechanical Engineers and the American Society for Testing Materials.

Piping for 1000-Degree Steam. J. H. Walker. *Heating, Piping & Air Conditioning*, Vol. 3, Apr. 1931, pages 283–287; *Power Plant Engineering*, Vol. 35, June 1, 1931, pages 606–608.

Short time tensile strength-temperature chart to temperatures of 1800° F. giving values on a Ni-Cr cast steel (1.8 Ni, 0.7 Cr), 0.44% C cast steel, and C seamless steel pipe is presented. Creep-stress-temperature chart to temperatures of 1600° F. give life on bases of 1% creep in 100,000 hours on 18% Cr 8% Ni steel and a 0.45% C steel. A general discussion on pipe design and installation as affected by temperature and pressure is presented. Much of the paper, however, is a review of previous work. WAT(29)

Some Considerations and Tests for Cast Materials for High-Temperature, High-Pressure Service. L. W. Spring. *Foundry Trade Journal*, Vol. 44, June 11, 1931, pages 399–404; Vol. 45, July 2, 1931, pages 7–10, 12; abstracted in *Metal Industry*, London, Vol. 38, June 19, 1931, pages 625–626.

The American exchange paper presented by Spring at the 28th Annual Convention of the Institute of British Foundrymen, held at Birmingham, England, June, 1931. After referring to changes in conditions which have to be met by cast materials in service, the author deals with improvements which have been effected in the manufacture of ferrous and non-ferrous alloys during recent years and then turns to the alloys which have been found suitable for resisting excessive corrosion in service, particularly those having a nickel or an iron base. He devotes considerable space to discussion of the strength of cast materials and deals with the correct design of specimens for the accurate testing of cast materials. The results of a number of short-time tests at high temperatures are referred to briefly, space being devoted to a fuller discussion of creep tests. The results of these tests are illustrated by a number of curves. The question of the deterioration of steels under stress and temperature and the application of creep data to engineering practice are dealt with in some detail. The paper ends with a discussion of wear tests and gives information regarding what is referred to as a score-testing machine. The paper is illustrated by 24 figures and diagrams. OWE+PRK(29)

Effect of Temperature on Materials in Turbine Design. S. H. Weaver. *General Electric Review*, Vol. 33, Nov. 1930, pages 654–655.

The present knowledge of steam turbine development in recent years is reviewed with reference to the flow of metals under stress at temperatures between 700° and 1000° F. Microscopic studies of several investigators for periods of 6 mos. are reviewed for a number of years relative to the creep of metals at 1000° F. The C content is discussed, it appears to have little influence at 1000° F., but is important at lower temperatures. WAT(29)

Determining the Temperature Conductivity Number and the Heat Conductivity Number of Heated Material when the Temperature Gradient is Measured. (Ermittlung der Temperatur- und Wärmeleitzahl von Glühgut aus dem gemessenen Temperaturverlauf.) A. Schack & E. Auhagen. *Archiv für Eisenhüttenwesen*, Vol. 4, Apr. 1931, pages 469–474; *Stahl und Eisen*, Vol. 51, May 14, 1931, pages 615–616.

Report No. 84 of the Rolling Mill Committee of the Verein deutscher Eisenhüttenleute. Whereas a previous investigation (*Stahl und Eisen*, Vol. 50, 1930, pages 1289–1297) considered methods for calculating the temperature course in the interior of the heated body when its surface temperature is known, the present investigation deals with the determination of the temperature conductivity number and the heat conductivity number by means of the measured temperature course. The calculation is based upon measurements of the temperature gradient of steel ingots in rolling mill furnaces and the temperature gradient of piled material, as borings, annealed wire, etc. In the first mentioned case, a comparison between calculation and measurement shows the temperature gradient between top and bottom surface of the ingots was calculated too large at the beginning of the heating but too small at the end of heating. This is due to the pronounced variability of the temperature conductivity number of Fe. In the beginning of the heating, the temperature conductivity number is much larger than the mean temperature conductivity number which has been used in the calculation. The conditions are reversed at the end of the heating. Taking into account the above systematic deviations from the mean temperature conductivity number, the temperature course can be calculated satisfactorily. The rapid decrease of the temperature conductivity number with increasing temperature is due to the increase of the specific heat and the decrease of the heat conductivity number. Other conditions prevail in heating piled material since, here, the radiation in the cavities plays a decisive rôle, for the radiation rapidly increases with the temperature. The temperature conductivity number of piled material is much less variable than that of solid bodies. The heat conductivity number of piled material increases with the temperature. The heat conductivity number of borings is small and of about the order of refractory bricks. Annealings in borings require a long time. GN(29)

The Specific Heat of Metals at Very Low Temperature. (Die specifisches Wärme von Metallen bei sehr tiefen Temperaturen.) J. N. van den Ende. *Metallwirtschaft*, Vol. 10, Aug. 28, 1931, pages 676–680.

Thirty-four references. Several theories on the lowering of the atomic heat at low temperatures and its relation to superconductivity are discussed. Recent measurements of specific heat of metals at temperatures of liquid H and lower have been made in Germany and Holland by the Nernst method. Details of the apparatus used by both schools are described, especially in regard to heat insulation, heating and temperature measurement. In the author's apparatus a copper core containing the heating and measuring wires was screwed into the metal block. The heating wire consisted of constantan and the thermometer wire of gold or constantan. He gas was admitted through a lead tube which was later closed by soldering. The results obtained agree in general with the Debije theory, but several exceptions have not been explained. At the He temperature, the specific heats of Hg, Pb, Bi, Zn and Sn have been determined. The specific heats of Pb and Bi at 3° to 20° K. are shown in graphic form. Still more accurate measurements are necessary for a complete understanding. CEM(29)

Direct Methods for Determining the Density of Melts, Especially of Metals at High Temperatures. (Ueber die direkte Auftriebsmethode zur Dichtebestimmung von Schmelzen, inbesondere von flüssigen Metallen bei hohen Temperaturen.) F. Sauerwald & E. Widawski. *Proceedings World Engineering Congress*, Tokyo, 1929, published 1931, Vol. 36, *Mining & Metallurgy*, Part 4, pages 1–4.

A displacement method, using a refractory plummet carried on an analytical balance, is described, and curves given for tin and copper. Specific volume of Sn with about 1/2% Sb ranges from 0.1484 at 600° C. to 0.1580 at 1280° C.; of Cu from 0.1260 at 1100° C. to about 0.1307 at 1500° C. HWG(29)

The Demands to be Made of Heat-Proof Metallic Materials and Their Testing. (Die anhitzebeständige metallische werkstoffe zu stellenden Anforderungen und ihre Prufüng). O. Hengstenberg & F. Bornefeld. *Krupp'sche Monatshefte*, Vol. 12, June 1931, pages 153–158.

In the first part of the paper, the properties required of heat-proof metals are discussed and it is pointed out that the selection of a material must be made for each individual case after collaboration of consumer and producer. The second part describes the testing methods which are especially important for new alloys. The test should imitate and take into account as much as possible conditions of actual service. Determinations of corrosion-resistance are particularly difficult in the laboratory at high temperatures for which some limits are given. 17 bibliographical references are included. Ha(29)

Heat-Resisting Alloys in Furnaces. L. J. STANBERY. *Heat Treating & Forging*, Vol. 16, Aug. 1930, pages 1031–1035; Sept. 1930, pages 1191–1196; Oct. 1930, pages 1322–1324, 1328.

Starting from the fundamental physical and chemical characteristics of alloyed metals, which are explained by their lattice configurations, the properties given to alloys by the use of various chemical elements and by heat treatment are described. The basic heat-resisting alloy is a combination of Cr, Fe and C with sufficient Ni added to maintain a normal austenitic structure at all temperatures below the δ-Fe or softening point. The analysis of several such materials is given and the heat treatment is described. The resistance to oxidation and to furnace gases at high temperatures is discussed; means are suggested for increasing it by proper alloying. Several types of stainless steels are analyzed and their treatment and characteristics and fields of application are described. Some directions and precautions for the use of these materials in design and foundry practice are given. Ha(29)

The Dependence of the Plasticity of Crystals on the Temperature. (Ueber die Temperaturabhängigkeit der Plastizität von Kristallen.) E. SCHMID. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 18, 1931, pages 23–25. Also in V.d.3. Intern Kongr. f. tech. Mech. Stockholm, 1930, page 249.

The critical translation-stress or beginning of plastic deformation of a single crystal is very low, some thousand to ten thousand-fold smaller than is called for by theory. It might be thought that at very low temperatures it might rise to the theoretical value, but at 1.2° and 4.2° absolute, the plastic deformation in Cd is still very low. After plastic deformation has started, the critical stress rises, i. e., the material work hardens and this hardening is very dependent upon temperature. In Cd it is very much more marked at −253° C. than at room temperature. It is also dependent on rate of deformation. The effects of both these factors affecting the work-hardening are ascribed to crystal recovery. At higher temperatures, the recovering follows the deformation more closely till finally deformation without hardening ensues. The energy of deformation of the Cd crystal is constant from 100° to 475° absolute. It is the thermal crystal recovery which prevents hardening through slip at high temperatures. The allowing of too short a time for this crystal recovery at ordinary temperatures may account for the "strengthening by understressing" through very tiny slipping of the crystal in endurance testing. HWG(29)

The Effect of Carbon and Silicon on the Growth and Scaling of Grey Cast Iron. A. L. NORBURY & E. MORGAN. *Iron & Steel Institute, Advance Copy* No. 11, May 1931, 22 pages; *Foundry Trade Journal*, Vol. 44, May 14, 1931, pages 338–343; *Iron & Steel Industry & British Foundryman*, Vol. 4, May 1931, page 276; *Engineer*, Vol. 151, May 22, 1931, page 566.

A study of growth of cast iron by dilatometric measurements indicated that growth of cast iron increased with increasing Si content up to 3 or 4%, but that as the Si was further increased growth decreased. More severe tests made by heating the iron to temperatures between 600° and 1000° C. in moist CO_2 confirmed this finding. Growth in the high Si irons resulted if the graphite flakes were very large. An iron was developed which contained from 4 to 10% Si with finely divided graphite, which is to be marketed under the name "Silal." Growth is attributed to (1) decomposition of combined C, (2) external and internal oxidation, and (3) crack formation. The ability of high Si iron to resist growth is attributed to the raising or obliteration of the α-γ transformation. Contains 13 references.
JLG+OWE+CHL+LFM(29)

The Fabrication of Pistons for Gas Engines and the Thermal Treatment of Cast Aluminum Alloys. (La fabbricazione dei pistoni per motori a scoppio e il trattamento termico delle leghe di a luminio da fonderia.) C. PANSERI. *La Metallurgia Italiana*, Vol. 23, June 1931, pages 500–522; July 1931, pages 624–643; Aug. 1931, pages 732–752.

A correlated abstract, to be published in 3 parts. The first part deals with coefficients of expansion, design of pistons, hardness and its importance in pistons, equilibrium diagrams for Al-Si, Al-Cu, Al-Mg_2Si, comments on the effect of additions of Ni, W, Li, Ti, B, V, effect of use of Cl and of the chlorides of Ti and B as degasifiers, and the modification of Al-Si alloys by Na, Ca, etc. Practically all the information given is available from other sources, most of it in English. Part 2. Some 70 aluminum piston alloy compositions, specifications and properties (where known) are given with trade names or designations. Short-time tensile tests at various temperatures are plotted. The strongest shown are at 250° C. "G97" (13.5% Cu, 0.8% Fe, 0.8% Mn) 31,000 lbs./in.^{2}; "RR53" heat-treated (2.25% Cu, 1.3% Ni, 1.6% Mg, 1.4% Fe, 0.1% Ti, 1.25% Si) 44,000 lbs./in.^{2} and alloy "X" heat-treated (3.6% Cu, 0.6% Mg, 1.25% Fe, 0.7% Si, 0.7% Ni) 34,000 lbs./in.^{2} The high Si, low expansion alloys are briefly discussed. Part 3. The rich alloys by which the alloying elements may be added are tabulated; the solidification shrinkage of the piston alloys and its bearing on methods of casting pistons, and finally the various casting methods and both melting furnaces and those for heat-treatment, are discussed. The series of articles forms a rather complete résumé of the subject. HWG(29)

Determination of the Creep Limit. W. ROHN. Publication in Honor of the 70th Birthday of Wilhelm Heraeus (Festschrift zum 70 Geburtstag von Wilhelm Heraeus), pages 80–96; 1930; published by G. M. Albertis Hofbuchshandlung, Bruno Clauss, Langstrasse 47, Hanau, Germany.

The fundamentals of creep are discussed, and the relation of creep to notched impact, tensile strength, yield point and elastic limit. Above certain temperatures, which differ for each material, tensile strength, yield point and elastic limit in the proper sense no longer exist, but converge asymptotically whenever the duration of the test amounts to several hundred or thousand hours. In the range of high temperatures, under the action of surprisingly small loads, a slight and gradually increasing creep of the material takes place. A new method of studying the creep characteristics is shown and the test method discussed. The test specimen itself provides automatic regulation of temperature and creep in the testing furnace after the manner of a dilatation thermometer. Starting with a cold test specimen in a cold furnace and switching on the heating current of the furnace, the furnace together with the test specimen gradually becomes heated, the test piece simultaneously increasing in length, being under a fixed load. As soon as a certain elongation is obtained, an electrical contact is actuated, shutting off the current to the heating element. If, subsequently, furnace and test specimen cool to a certain extent, and so contract, the contact is reconnected, the heating current is once more applied and the specimen reheated so that the cycle starts over again. The limits within which this process takes place are from 4–8° C. This cycle repeats indefinitely as long as the fixed load on the test piece is below the creep limit of the material under test. If, however, the load is greater than the creep limit, besides the alternating thermal elongation and contraction a gradual elongation due to creep will occur. The furnace temperature in such a case will gradually decrease to a temperature at which a permanent elongation under the influence of the load no longer takes place. This temperature will then remain constant. The load carried by the specimen is the creep limit at this temperature. Only a few preliminary experimental results are reported. An alloy containing 15% Cr, 7% Mo, 16% Fe, 60% Ni and 2% Mn annealed at 1050° C. showed a creep limit of 427 lbs./in.^{2} at 838° C. by this method, the temperature having dropped in 48 hours from 1080° to 838° C. before equilibrium was reached. WAT(29)

REDUCTION METALLURGY (31)

Production of Ferro-Titanium. S. S. STEINBERG & P. S. KUSAKIN. *Transactions Institute Economic Mineralogy & Metallurgy*, Moscow, 1929, No. 43, pages 5–44.

The object of this investigation is to determine the conditions of reduction by C of Ti from ores rich in TiO_2 in the process of preparing ferro-carbo-titanium, and to investigate the possibilities of obtaining the commercial alloy under the conditions existing in the Urals. The experimental work consisted in determining the following: 1. Influence of temperature on reduction of Ti. 2. Influence of Ti concentration in the melt on reduction temperatures. 3. Influence of slags on reduction temperatures. 4. Reduction of Ti from titano-magnetite. The following materials were used in the investigation: 1. Titanium ore containing 50–56.5% TiO_2, 34.25–48.55% FeO and 2.27–4.5% MnO. 2. Titano-magnetite with 10.2% Ti. 3. Coke, gray iron and fluxes: CaO, MgO, Al_2O_3 and CaF_2. All laboratory melts were made in a Tammann electric furnace in small graphite crucibles. Thirty-two melts were made, varying in temperature and composition of the charge. In the experiments on larger scale conducted at Zlatoust works in a Steinberg and Gramolin electric resistance furnace, the maximum Ti content obtained in the alloy was 1%; the remaining Ti went to slag. This type of furnace was not suited for the preparation of the alloy because the required high temperatures could not be obtained. Using an arc furnace, 80–90% reduction of Ti was obtained with an energy consumption of about 13 kw.-hrs./kg. of ferro-titanium. Attempts to make large melts in a large electric arc furnace at Porogi Works gave negative results owing to the unsuitability of the furnace, which was designed for steel melting but not for making ferro-alloys. Thermodynamic calculations for the reduction of Ti by C made by the authors show that TiO_2 can be reduced by elementary C, not by CO. The theoretical temperature of complete reduction of TiO_2 to Ti was found to be 1897° C.; 100% reduction is impossible in practice because of the large excess of C. Temperatures of reduction of Ti in ferro-titanium ores of varying Ti content (0–100% Ti) and with varying CO pressures were calculated. Curves are given showing elation between Ti concentration, temperature and partial pressures of CO. These curves show that lowering Ti concentration in the melt lowers the temperature of its reduction and, therefore, the temperature of the whole reduction process. This is in full agreement with experimental results. The curves also show that the reduction temperature depends on the concentration of CO in the furnace atmosphere. Conclusions: Temperature of reduction of Ti from ferro-titanium ores depends (at the same CO concentration in the atmosphere) on the Ti content in the charge. The lower the Ti content the lower the temperature of complete reduction. With the concentration of Ti in the charge necessary to obtain 5% Ti ferro-titanium alloy, complete reduction of Ti is obtained at 1480° C; 10–12% Ti alloy is obtained at about 1680°. Further increase of Ti content (carbide) in the melt raises the melting temperature because the melting point of Ti carbide is very high (3170° C.). Alloy with 14–18% Ti and 5–7.5% C can be obtained only at temperatures above 1680–1750°. In preparing alloys with 19–21% Ti, 80% reduction is obtained at 1700° and 92% at 1940°. Therefore, under the existing plant conditions (Ural) the preparation of ferro-carbo-titanium alloy with Ti content above 20% is impracticable. Alloy with 21% Ti and 0.10% C melts at 1400–1420° C. which is in accordance with the Fe-Ti equilibrium diagram. Because of the easier formation of the Ti carbide than of metallic Ti in the furnace, it is easier to obtain ferro-carbo-titanium than low C ferro-titanium. The latter can be obtained by reduction with Al. On the basis of these experiments, the following recommendations are presented as to the furnaces and the process of obtaining ferro-titanium: (a) Arc furnaces are best suited for obtaining high temperatures necessary in the process; (b) a steel melting type of furnace with an arched roof is suggested in order to heat both the metal bath and the slag; (c) Ti is reduced from Ti ore covering the metal bath in the form of slag by the C of the bath wherefor the bottom should be made of coke; (d) no addition of fluxes (lime) is needed because it raises the reduction temperature of Ti; the charge should consist of ore, coke and scrap iron in corresponding proportions; (e) a Siemens type furnace with one upper moving electrode and one bottom electrode is best suited for the process; (f) either ilmenite or titano-magnetite can be used as the ore. Sketches of the furnaces and complete records of all melts are given. BND(31)

The Production of Pig Iron with a High Content of Alumina in the Burden. (Die Erzeugung von Roheisen bei einem hohen Tonerdegehalt des Möllers.) M. PASCHKE & E. JUNG. *Archiv für Eisenhüttenwesen*, Vol. 5, July 1931, pages 1–8.

The pig iron was made of a burden of scrap, bauxite and limestone. The slag contained on the average 7% SiO_2, 40% CaO and 45% (Al_2O_3 + TiO_2). The average composition of the pig iron produced is C, 5%; Si, 0.3%; Mn, 0.5%; P, 0.13%; S, 0.02%; Al, 0.02%. The high carburization of the pig iron is due to the viscosity, amount and temperature of the slag and the small content of Si is due to the low Si concentration of the burden. The structure of the pig iron is purely pearlitic and the graphite is most favorably crystallized. The amount and temperature of the slag favor a far reaching desulphurization of the pig iron. The heat balance of the blast furnace is dealt with. Running the furnace with such a high content of alumina in the burden offers no difficulties. GN(31)

Some Aspects of the Iron Ore Situation. F. B. RICHARDS. *Mining & Metallurgy*, Vol. 11, Sept. 1930, pages 435–436.

A discussion of present condition of ore supplies and of the question of the successful commercial use of the enormous tonnage of low grade ore by proper concentration for the blast furnace. Ha(31)

Experimental Investigations of Different Gas Burners of Blast Furnaces. (Recherches expérimentales sur différents brûleurs au gaz de hautsfourneaux.) MARCEL STEFFES. *Revue Technique Luxembourgeoise*, Vol. 23, May–June 1931, pages 106–108.

A classification of gas burners according to aerodynamic and thermal qualities has been attempted. Questions of investment costs, cleaning and maintenance prevent the results from being conclusive. Ha(31)

Gasification of Fuel and Simultaneous Treatment of Ores by Fusion and Volatilization. (La gazéification des combustibles et le traitement simultané des minerais par fusion et volatilisation.) H. PHILIPON. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 437–439.

By treating ferruginous schists, limestone and low-grade coke in a slagging type gas producer, one can simultaneously make gas, high Si pig iron and a slag which can be made into cement. By adding 20% cast iron to the charge, the Si content can be lowered to 2% instead of 9% without such addition. With low S fuel and the use of limestone, the pig produced is low in S. At Vieille-Montagne, the producer is run with the addition of Zn ores or zinc oxide residues, and much of the Zn recovered as dust. Since the efficiency of the producer is about 70%, low grade ores can be treated. HWG(31)

Germanium—XXXVI. Extraction of Germanium and Gallium from Germanite—I. W. I. PATNODE & R. W. WORK. *Industrial & Engineering Chemistry*, Vol. 23, Feb. 1931, pages 204–207.

Eleven references. The process consists in: (1) the direct chlorination of the dry ore and collection of the distillate of anhydrous chlorides; (2) the fractional distillation of the anhydrous chlorides and subsequent hydrolysis of the distillate; (3) the distillation of germanium tetrachloride from the products of hydrolysis and subsequent conversion of the tetrachloride to the dioxide. MEH(31)

ALPHABETICAL INDEX TO ADVERTISERS

MANUFACTURERS' LITERATURE REVIEWS

In this department we each month list the catalogs and other printed matter issued by manufacturers. Unless otherwise noted, any of the items listed may be secured free upon application to the issuing firm. Manufacturers who have not yet sent in their printed matter are invited to do so.

101 **Modern Refractory Practice.**—The Harbison-Walker Refractories Co., of Pittsburgh, Pa., has published a most complete book on the subject of refractories. Its 178 pages contain a discussion of fireclay, alumina, silica, magnesite and chrome refractories, many tables and formulae useful in their application and much general information on the subject.

102 **Allegheny Metal in Dairy Equipment.**—The Allegheny Steel Co., Brackenridge, Pa., has prepared reprints of an address to the Dairy Engineers' Institute at the National Dairy Exposition in October As its name indicates it is a discussion of results obtained from the use of austenitic chromium nickel steel, commonly known as "18-8," in dairy equipment.

103 **Bright Annealing.**—The Process Engineering & Equipment Corporation, 5 Falmouth St., Attleboro, Mass., makes special furnaces for bright annealing in one operation. A folder issued by them shows one of their installations.

104 **Vanadium Steels.**—The Vanadium Corporation of America has recently revised and re-issued its specifications 3B to 9B inclusive, covering vanadium steels for various purposes. Copies of the new specifications can be obtained from the company.

105 **Refractories.**—Corhart "Electrocast" is a new refractory produced by a patented process. It is said to have a porosity of less than 0.5% and has a fusion point of cone 35. "Electroplast," made by the same company, is a plastic refractory used for patching or for applying as a protective coating on refractory walls or bottoms.

106 **Combustion Control.**—Bulletin No. 660 describes L & N Metered Combustion Control equipment by which metered quantities of fuel and air are supplied to each boiler and uniform steam pressure and correct furnace pressure are maintained. The bulletin is fully illustrated. The company also issued several bulletins on their Hump hardening method and their Homo heat-treating furnaces.

107 **Bronze.**—Interesting pictures of the bronze work in the new Waldorf-Astoria are reproduced in the December issue of the Bulletin of the Copper & Brass Research Association. Several unusual applications of copper and brass are also discussed.

108 **Liquid Heating Furances.**—A recent folder sent out by the Surface Combustion Corporation, Toledo, Ohio, describes an installation of one of their continuous lead hardening furnaces designed for hardening ninety hubs an hour.

109 **Castings.**—An attractive booklet prepared by The British Aluminium Co., Ltd., 122 East 42nd Street, New York, gives technical details on melting practice for aluminum alloys, specifications for casting alloys and heat treatment of aluminum alloy castings.

110 **Metal Spraying.**—A folder issued by the Metallizing Company of Los Angeles, Ltd., 1218 Long Beach Ave., Los Angeles, describes a new gun they have developed for metal spraying. It can be used to give non-metallic products the appearance of solid metals or to make some metallic product rust-proof. Cloth can be sprayed with metal and so can glass, plaster and most other materials.

111 **Pot Furnaces.**—Bulletin No. 10 of the American Electric Furnace Co., Boston, Mass., is devoted to their Model P—Cylindrical Type Pot Furnaces. A cross-section diagram of the furnace is shown.

112 **The Laboratory.**—The Vol. 4, No. 4, issue of this publication of the Fisher Scientific Co., Pittsburgh, Pa., contains accounts of a new hot wire cutter for the laboratory, a new temperature recorder and a new vacuum meter.

113 **Recording Instruments.**—Bulletin GEA-1061D of the General Electric Company describes their strip-chart recording instruments for alternating and direct current and gives data on their switchboard voltmeters and ammeters.

114 **Pyro Rapid Recorder.**—The Pyrometer Instrument Co., 103 Lafayette St., New York, has sent out a pamphlet announcing their rapid recorder radiation tube for measuring the temperature of fast moving objects or rapidly changing temperatures.

115 **Gears Made of Armor Plate.**—The International Nickel Company, 67 Wall St., New York, has issued reprints of an article which appeared in *Metal Progress*. It is concerned with two nickel alloy steel compositions which have proved reliable in rear axle and transmission gear construction.

116 **Cataract Metal.**—This is an alloy developed by the Niagara Falls Smelting & Refining Corp., Buffalo, N. Y. It is a nickel base alloy of silver white color and is discussed in a leaflet sent out recently by the company. It has great ductility, high tensile strength and chemical resisting powers.

117 **Grinding.**—The October issue of *Grits and Grinds*, published by the Norton Company, Worcester, Mass., features an article entitled "Grind Side Milling Cutter" and a write-up on the Norton Automatic Cam Grinder.

118 **Alloy Steel Castings.**—An attractive pamphlet prepared by the Duriron Co., Inc., Dayton, Ohio, discusses the corrosion resistance of their Durimet and Durco Nirosta and gives technical data concerning them.

119 **Electric Decorating Kiln.**—Bulletin K-101 of the Ajax Electric Co., Inc., Philadelphia, Pa., is devoted to their electric circular decorating kilns.

120 **Pickling.**—Several circulars on their rotary pickling machine can be obtained from N. Ransohoff, Inc., W. 71st St. at Millcreek, Cincinnati, Ohio. A photograph of the equipment will be furnished if desired.

121 **Foundry Practice.**—An interesting article on cupola refractories is the keynote of the December issue of *Better Methods*, published by Beardsley & Piper Co., 2541 North Keeler Ave., Chicago, Ill.

122 **Carbon Tetrachloride.**—This booklet published by the Roessler & Hasslacher Chemical Co., Niagara Falls, N. Y., contains information on the properties, specifications and commercial application of the non-flammable solvent, carbon tetrachloride.

123 **Electric Foundry Equipment.**—Bulletin GEA-1413 of the General Electric Company is devoted to a full exposition of their electric equipment for foundries. It is a profusely illustrated booklet of 50 pages and contains a list of other G-E publications of interest to foundrymen.

124 **Zinc Die Castings.**—The New Jersey Zinc Company, 160 Front St., New York, has compiled a booklet containing many unusual pictures of zinc die castings, from toy autos to parts for motion picture cameras and phonographs.

125 **Plykrome.**—This stainless composite steel is discussed in a folder sent out by The Plykrome Corporation, 225 Broadway, New York. It is chromium iron or high-chrome, high-nickel stainless alloy as an integral surface on a backing of mild steel and can be rolled from any alloy which best answers the specific service requirements encountered.

126 **Industrial Heating Equipment.**—Bulletin No. 320 of the W. S. Rockwell Co., 50 Church St., New York, gives a number of typical illustrations of Rockwell electric and fuel furnaces used in the metallurgical, ceramic and chemical industries.

127 **Steel-Mill Motors.**—Bulletin GEK-71 of the General Electric Company describes their type MD Steel-Mill motors especially built for rough service. Specifications for the different size motors are given.

128 **Udylite.**—An interesting application of this plating process is revealed in the August issue of *The Udylite News*, published by the Udylite Process Co., 3220 Bellevue Ave., Detroit, Mich.

129 **Chemical Equipment.**—Booklet No. 100 issued by the F. J. Stokes Machine Company, Tabor Road, Philadelphia, Pa., describes their complete line of chemical, pharmaceutical and special process equipment.

130 **Springs.**—The October issue of the *Mainspring*, published by the Wallace Barnes Co., Bristol, Conn., features an article on "Flat Springs, a few Suggestions Regarding their Design."

131 **G-E Thrustor.**—The General Electric Company has issued a pamphlet announcing their thrustor which is a new electric device which exerts a smooth, powerful thrust. It can be installed on hand- or foot-operated machines. Their bulletin GEA-1262A gives full information on this line of equipment.

132 **Hipernik.**—The International Nickel Company, 67 Wall St., New York, has issued as a reprint an article entitled "Permeability of Hipernik reaches 167,000" written by T. D. Yensen which appeared in *The Electric Journal.*

133 **Chrome Brick.**—Bulletin 1-13-15 of the E. J. Lavino & Co., Bullitt Building, Philadelphia, Pa., stresses the unusual chemical and refractory properties of chrome ores in the manufacture of refractories. Physical properties of brick made by their improved process are illustrated. Several of their pamphlets show the application of these bricks in basic open-hearth furnaces, in soaking pits and recovery furnaces.

134 **Refractories.**—Hytempite is a dense, plastic refractory material, scientifically compounded, for bonding fire brick and for kindred uses. A 23-page booklet giving numerous suggestions for its application has been compiled by the Quigley Company, Inc., 56 West 45th St., New York. A leaflet published by the same company discusses their dry refractory cement, Pyro-mortar.

METALS & ALLOYS, 3619 Forbes St., Pittsburgh, Pa.

Tensile Properties and Stress. (Festigkeitseigenschaften und zulässige Spannungen.) E. SIEBEL. *Stahl und Eisen*, Vol. 51, June 25, 1931, pages 785-788.

Report No. 176 of the Committee on Materials of the Verein deutscher Eisenhüttenleute. The properties of materials which must be taken into proper consideration for the manifold types of application are discussed. The author endeavors to settle the question as to what tensile properties the calculations of the construction engineer must be based upon and to what extent the fundamental properties have been investigated. Proposals are made as to the accumulation of data for the calculations of the constructor. GN(0)

Possible and Efficient Quality Requirements and Their Increase by Mass Production. (Mögliche und zweckmässige Güteanforderungen und ihre Steigerung durch die Massenerzeugung.) K. SCHIMZ. *Stahl und Eisen*, Vol. 51, June 11, 1931, pages 729-734.

Report No. 175 of the Committee on Materials of the Verein deutscher Eisenhüttenleute. Includes discussion. The article gives a résumé on the experience in manufacturing bolts and nuts; discusses in detail the failures and outlines the remedies. It is shown that at any rate mass production necessitates an increase of the quality of the material used. Producer and consumer should coöperate to this end. GN(0)

When Designing Steel Castings. ERNEST VEIHL, JR. *Product Engineering*, Vol. 2, Aug. 1931, pages 352-354.

The designer must be absolutely familiar with the mechanical properties of the materials to be employed and the means of shaping castings to obtain a good foundry product. This is particularly important in the case of very large castings of complicated form. Ha(0)

Theory and Practice. (Wetenschap an Techniek.) A. VOSMAER. *De Gieterij*, Vol. 5, June 1931, pages 78-79.

In dealing with alloys, volume percentages would be more useful than either weight percentages or atomic percentages. HSvK(0)

Weight of Monel Metal Sheets. J. K. OLSEN. *Metal Stampings*, Vol. 4, Mar. 1931, page 266.

This table gives weight in lbs./ft.^{2} for monel metal sheet ranging in thickness from 2 in. to $^9/_{16}$ in. and from No. 0000000 (= $^1/_2$ in.) to No. 38 U. S. Standard gage. Weight/ft.^{3} equals 558.14 lbs. JN(0)

Iron and Steel Metallurgy in 1930. CLYDE E. WILLIAMS. *Mining & Metallurgy*, Vol. 12, Jan. 1931, pages 32-36.

Review of the progress made during the year in blast furnace practice, the physical chemistry of steel making and in the rapidly increasing uses of corrosion-resistant steels. Ha(0)

Metallurgical Terms. *Metallurgist*, Apr. 1931, pages 49-50.

The scientific metallurgist is sometimes accused of employing abstruse technical terms when stating the results of his researches, with the consequence that the "practical man" is, for that reason, unable to understand what the scientific man has done or what he means. The scientific investigator, attacking new fields of knowledge, is bound to develop new ideas as well as to discover new facts, and for these new conceptions he must necessarily employ new or at least special and precisely defined terms if he wishes to record—as he must—exactly determined results in equally exact language. The coining of new terms is, therefore, scarcely to be avoided but they should be limited to as few as possible. The present habit of applying different meanings to the same word is also confusing. "Metallurgy," while applying to everything relating to the science and art of reducing metals from their ores, is also applied more specifically to the physical properties and heat treatment of metals and alloys. "Physical Metallurgy," while an improvement, still does not cover the subject. In France, the whole field is covered by "Metallographie" which, by English-speaking scientists, denotes only the microscopic examination of metals. The ability of a metal or alloy to improve its physical properties by heat treatment, usually quenching followed by aging, has acquired the term age-hardening. In German, this quality is denoted by the very satisfactory adjective "vergütbar." However, the Deutsche Gesellschaft für Metallkunde has decided to replace this word with "aushärten" apparently to make a distinction between quenching and tempering as opposed to quenching and aging. Apparently all that can be hoped for in metallurgical terminology is the gradual development of a simple, logical and consistent system which the increasing intercourse and exchange of ideas between the workers of different nationalities will lead to the establishment of definitely equivalent terms between the different languages concerned. PROPERTIES OF METALS (1)

The Problem of the Electrical Conductivity of Metals. C. D. NIVEN. *Canadian Journal of Research*, Vol. 5, July 1931, pages 79-86.

The author points out that mathematicians, in attempting to form theories of electrical conduction, lay no emphasis on the fact that resistance, as a rule, does not vanish at low temperatures. When it does, it vanishes suddenly. The question, therefore, arises as to whether the right model for conductivity in a metal is visualized. The author suggests that fundamentally a metallic atom is one in which the electron configuration is incomplete. Ordinary conduction is a process whereby the electron jumps from one atom to another, remaining with the atom it jumps to until it is in equilibrium with the motions of the electrons already on that atom. In the super-conducting state, the electronic orbits of different atoms become synchronized so that when an electron leaves one atom, another electron immediately arrives to take its place. Studies of the resistance-temperature curves and of other phenomena emphasize the importance of structure in conductivity. OWE(1)

Pure Metals. (Reine Metalle.) WALTER NODDACK. *Metallwirtschaft*, Vol. 10, Aug. 28, 1931, pages 674-676.

For certain physical measurements, metals of exceptional purity are necessary. Many disagreements in measurements by different investigators have been traced to metals of different purity. The purity of metals is sometimes limited by the available analytical methods. The process of obtaining pure metals consists of determining the impurities, producing a pure metallic compound and separating the metal from its compound. The purity can be checked by measuring the temperature coefficient of electric conductivity, resistance at low temperatures, hardness, electric conductivity in a strong magnetic field, by obtaining the optical or X-ray spectrum or by numerous chemical reactions. Some chemical methods are sensitive to 10^{-9}. Fractional crystallization and distillation are frequently used to obtain pure compounds. Reduction to the metal is accomplished by thermal, electrical or chemical means, especially by melting in a vacuum, the production of wires by thermal dissociation of gaseous metallic compounds or by electrolytic plating in sheet form. A number of metals have been produced with total impurities 10^{-3} to 10^{-5}. CEM(1)

Technology and Tensile Properties of Pure Aluminum. (Technologie und Festigkeitseigenschaften von Reinaluminium.) G. SACHS & J. WEERTS. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 3, Apr.-June 1931, pages 182-236

Three grades of pure aluminum are commercially produced: (a) Al 99.5 with more than 99.5% Al (in America, "special"); (b) Al 99 with more than 99% Al ("grade 1" or "grade A" in the U.S.A.); (c) Al 98/99 with 98-99% Al ("grade 2" or "grade B" in the U.S.A.) Al with 99.7 to 99.8% can be had without difficulty; the impurities are Fe, Si or traces of Cu. The Aluminum Company of America produces an aluminum of 99.8 to 99.9% which has a somewhat lower tensile strength. The influence of the impurities is explained. A complete treatise on casting, influence of casting temperature, machining, workability, pressing, drawing, tools for cutting, milling, threading, boring, sawing, filing, grinding is given. Heat treatments for obtaining recrystallization and certain properties are described in detail. Tensile properties and electric conductivity are tabulated for different degrees of purity. Extensive tables which show the influence of annealing of different durations on the tensile strength are added. The crystal structure is exhaustively discussed and directions are given for the production of uni-crystals (crystals in which one crystal fills the whole section and has a sufficient length for undisturbed behavior during working). The mechanical properties, their tests and results are described by means of tables, curves and formulas. A separate chapter is devoted to the influence of temperature and is illustrated by curves. Corrosion is treated in the same manner. The paper is supplemented by a list of 269 references. Ha(1)

Compressing Powdered Carbonyl Iron by Treatment with Heat and Compression. (Ueber die Verfestigung von pulverförmigen Carbonyleisen durch Wärme- und Druckbehandlung.) L. SCHLECHT, W. SCHUBARDT & F. DUFTSCHMID. *Zeitschrift für Elektrochemie*, Vol. 37, Aug.-Sept. 1931, pages 485-492.

Carbonyl iron is the product of the thermal disintegration of iron carbonyl when metallic iron is formed under the development of carbon monoxide. It is an extremely fine iron powder and consists of small spheres of a diameter of 1×10^{-3} cm. to 1×10^{-4} cm. Carbonyl iron shows a remarkable crystal growth when heated; this quality is ascribed to its purity, the low temperature of its formation and the small size and sphericity of the powder particles. It has an extraordinary ability to sinter which makes a technical production and application of carbonyl iron possible. It is very soft and possesses a deep-drawability like Cu. Its technological properties, hardness, elongation, elastic limit, tensile strength are as good as those of pure Fe produced by smelting. It is more resistant to corrosion than other types of pure Fe and has a high original permeability (μ_0 = 3000) and a low coercive force (H_c = 0.07) when annealed in vacuum in a current of H. The carbonyl iron alloys are equally excellent with regard to mechanical and magnetic properties, due to freedom from S and P. In the discussion, several points concerning precipitation of a metal from a gas were mentioned. 13 references. Ha(1)

Some Electrical Properties of Spectroscopically Pure Zinc Crystals. A. G. HOYEM. *Physical Review*, Vol. 38, Oct. 1931, pages 1357-1371.

With single crystal specimens of spectroscopically pure (99.9999%) Zn, the Thomson coefficient at 49.5° C. has been measured as a function of orientation. A very accurate confirmation of the Voigt-Thomson symmetry relation is obtained; the principal values of the Thomson coefficient are $\sigma\perp = 0.86 \times 10^{-6}$ cal./coul./deg., and $\sigma\parallel = 0.34 \times 10^{-6}$ cal./coul./deg. The thermal e. m. f. of these same specimens against Cu has been determined as a function of orientation throughout the temperature range −180° to 200° C. From these data, the values of the Peltier coefficient, the Thomson coefficient and the difference in principal Thomson coefficients have been computed as functions of temperature by means of the relations given by the Kelvin thermodynamical theory of thermoelectricity. The values of the Peltier coefficient of Zn⊥ against Zn= thus obtained are π = 658 microvolts at 49.5° C. and π = 1080 microvolts at 125° C. For the difference in the principal Thomson coefficients, the values are $\sigma\perp - \sigma\parallel = 0.58 \times 10^{-6}$ cal./coul./-deg. at 49.5° C. and $\sigma\perp - \sigma\parallel = 1.20 \times 10^{-6}$ cal./coul./deg. at 125° C. The predictions of the Kelvin theory regarding $\sigma\perp - \sigma\parallel$ are thus found to be in agreement with the direct determinations by Ware and the author. The Voigt-Thomson law is found to hold also in the case of thermoelectric power and the other thermoelectric properties to which it should apply. The dependence of resistivity on temperature has been investigated for the temperature range −170 to 25° C. The average value of the temperature coefficient of resistivity obtained is $\alpha = 4.058 \times 10^{-3}$. For comparison purposes, a direct determination of the Thomson coefficients of single crystal specimens of pure Zn (Kahlbaum's best Zn) at 49.5° C. has also been made, as well as a study of the dependence of their resistivities on temperatures. For this less pure Zn the principal values of the Thomson coefficient are $\sigma\perp = 0.91 \times 10^{-6}$ cal./coul./deg. and $\sigma\parallel = 0.38 \times 10^{-6}$ cal./coul./deg. For the temperature coefficient of resistivity, the average value is $\alpha = 4.009 \times 10^{-3}$. A variation in the values of α for specimens of the same grade of Zn is observed which is considerably greater than can be attributed to experimental error. WAT(1)

The Chemistry and Metallurgy of Beryllium. G. M. DYSON. *Chemical Age*, London, Vol. 24, No. 611, 1931, pages 228-230.

A review of the known properties of Be and the possibilities of its practical application. Ha(1)

The Photoelectric Effect in Metals. **(Zum Photoeffekt an Metallen.)** Herbert Fröhlich. *Annalen der Physik*, Vol. 7 (5), No. 1, 1930, pages 103–128.

On the basis of Sommerfeld's wave-mechanical electron theory, a theory of the photoelectric effect in thin layers is developed. With the alkali metals, this theory yields intensity values and maxima for current and light frequency which agree in general with experimentally obtained values. The difference in behavior of a surface toward fast and slow electrons accounts for the direction of polarization. For fast electrons, the atomic structure of the surface is important; for slow electrons, the surface may be regarded as smooth. The distribution of energy of the photoelectrons shows a strong maximum near the maximum velocity. Ha(1)

The Melting Point of Pure Chromium. **(Ueber den Schmelzpunkt des reinen Chroms.)** F. Hoffmann & C. Tingwaldt. *Zeitschrift für Metallkunde*, Vol. 23, Jan. 1931, pages 31–32.

The melting point of pure Cr was determined by an optical pyrometer in 2 ways. In the first, the metal was melted in a high vacuum in a magnesia crucible, and a value of 1800 ± 10° C. was obtained. In the second, the metal was melted by the heating effect of electric current passing through it, and a value of 1765 ± 10° C. was obtained. The reason for this difference is not clear. RFM(1)

Brinell Hardness and Tensile Strength. W. Rosenhain. *Metallurgist*, June 1931, pages 83–85.

The close proportionality between the Brinell test and tensile strength would indicate that the phenomena occurring in the 2 tests were very similar. This is not surprising when it is realised that in both, the material is being subjected to plastic deformation which largely takes place by shear, and that the tensile and compressive properties of steels in a normalized or annealed condition are very similar. The indentation test, therefore, like the tensile test, can be to some extent regarded as a means of measuring the resistance of the material to plastic deformation. However, this relationship does not hold with other metals and alloys. In certain limited groups of alloys there is a proportionality between the 2 sets of data, but the numerical value of the ratio is different from that applicable to steel. On the other hand, there are types of alloys in which there is no proportionality between indentation hardness and tensile strength. In the case of copper containing 0.7% iron it is found that the Brinell number can be raised by age-hardening from 35.8 to 52.5. This result is obtained by first quenching the material from a temperature of 1000° C. and following this by reheating for some hours at 500° C. Yet, in spite of an increase of Brinell number of nearly 50%, the tensile strength only increases from about 13 to 15 tons/in.² A similar observation has been made in regard to the alloys of pure Cu with oxygen (Hanson, Marrayat & Ford. *Journal Institute of Metals*, Vol. 30, 1923, page 197), while in the alloys of the same metal with 0.95% P the Brinell number can be increased from 43 to 52 by quenching and reheating, but there is no appreciable increase in the tensile strength (Hanson, Archbutt & Ford. *Journal Institute of Metals*, Vol. 33, 1930, page 41. See *Metals & Alloys*, Vol. 1, page 788). The author therefore considers the mechanism of deformation as it exists in both the tensile test and the indentation process to find an explanation of these phenomena. His explanation is based upon the consideration of the extent to which intercrystalline cohesion in ordinary polycrystalline metal enters into the results of both tensile and indentation tests. In steel at room temperatures, and in a great many of the stronger metals and alloys, intercrystalline cohesion is so great that by whatever method fracture is produced, it always occurs mainly if not wholly by rupture of the crystals themselves and not by the separation of the crystals from one another—the material fails by trans-crystalline and not by inter-crystalline movement. At elevated temperatures—and in some metals a very slight rise of temperature is sufficient—the intercrystalline cohesion becomes weaker than the resistance of the crystals themselves and the material fails by intercrystalline rupture. Age-hardening is believed to occur as the result of the precipitation, in a state of extremely fine division, of material present in a solid solution in a state of super-saturation. Iron, for instance, is considerably more soluble in solid Cu at 1000° C. than at 500° C., and if the alloy, after annealing at 1000° C., is quenched, and is thereby maintained in the condition of a solid solution, hardening can be brought about by reheating at 500° C. This causes a precipitation of the excess of iron which had been retained in solid solution by quenching. The precipitation of the particles disturbs the regular space-lattice of the Cu and thereby increases resistance to deformation by crystalline slipping. If this view of age-hardening is correct, we should anticipate an increase in the hardness and strength of the crystals of the metal, but it is an open question whether such a precipitation process can have, in itself, any effect on inter-crystalline cohesion. The author's view on this point, based on the conception that there is an intercrystalline layer of more or less non-crystalline or amorphous material between adjacent crystals, is that precipitation, if it occurs at all in these layers, cannot further harden them, since there is no slip mechanism which can be hampered by the presence of dispersed particles. Only where comparatively large quantities of relatively large molecules or crystallites of an inter-metallic compound are deposited from or formed in the alloy matrix need there be any great effect on boundary strength. In such a case, the presence of any considerable number of large molecules or particles would serve to increase the effective viscosity of the intercrystalline layer and thus would serve to raise boundary strength. However, it is only necessary to appreciate the fact that age-hardening, and other methods of increasing the strength of an alloy, may in certain cases increase only the strength of the crystals themselves without altering the boundary strength. Let us now consider the the effect on indentation hardness and tensile strength respectively of a process which increases the hardness and strength of the crystals themselves without materially affecting boundary strength. The result will depend upon whether, in the initial unhardened state, the boundary strength was very considerably, or only slightly, greater than the strength of the crystals. In the former case—where the crystal boundaries are very much stronger than the crystals, the effect of hardening the crystals themselves will clearly be to increase the resistance of the material to plastic deformation of all kinds, and we should expect to find Brinell number and tensile strength increasing proportionately together. This appears to be the case with steel in which, even at slightly elevated temperatures, inter-crystalline rupture can only be produced with the aid of chemical attack. On the other hand, where, in the initial state of the metal, the boundary strength is only slightly higher than the crystal strength, any hardening of the crystals will only produce a slight increase of tensile strength, since rupture will soon occur at, or be initiated by, the failure of the crystal boundaries. Under compression, however, as in the indentation test, the strength of the crystal boundaries does not enter into the question to anything like the same extent, and the indentation test is thus a measure more of the hardness and strength of the individual crystals than of the aggregate. Where, therefore, it is the strength of the crystals which governs the strength of the material, i. e., where intercrystalline cohesion is high, tensile strength and Brinell number will be more or less proportional; but where inter-crystalline cohesion is not very high, there will be little or no relationship between the 2 types of test. This explanation appears to cover satisfactorily the behavior of mild steel and of many alloys, both at ordinary and elevated temperatures. It suggests that in a single crystal the relation between indentation hardness and tensile strength should be particularly close, since boundary strength does not enter into the matter. On the other hand, the mode of deformation of a single crystal is of a peculiar kind, and it might be found that this affects the indentation test in such a way as to interfere with proportionality to the tensile strength. VVK(1)

PROPERTIES OF NON-FERROUS ALLOYS (2)

Konel. J. S. Negru (International Nickel Co.). *Metal Industry*, London, Vol. 37, July 4, 1930, page 15.

Brief letter giving the composition of Konel Metal developed by the Westinghouse Electric & Mfg. Co. VSP(2)

Steel and Light Metal. **(Stahl und Leichtmetall.)** P. Schwerber. *Metallbörse*, Vol. 20, July 26, 1930, pages 1658–1659; Aug. 9, 1930, page 1771.

Rustless light metal possesses all the good qualities of steel, besides its own, without the disadvantages of the latter. It is superior to steel because of its low specific gravity (about 2.8), permitting a decrease in weight in constructions of about 60%; greater safety despite a possible decrease in weight, under certain conditions, of 90%; absolute freedom from rusting, obliterating the necessity for protective coatings; longer life; greater thermal and electrical conductivity. It permits of great economic saving. Its use is ushering in a new industrial era. WHB(2)

Aluminium Alloy. *Electrician*, Vol. 107, Sept. 18, 1931, page 384.

A new light alloy with remarkable properties, designated M.V. "C" has been produced by the Metropolitan-Vickers Electric Co. Ltd. It is an Al-Si alloy prepared by a new method. Outstanding properties are strength and ductility. The ultimate strength is 9–11 tons/in.² when sand cast, and 11–13 tons/in.² when chill cast. The alloy can be rolled, drawn, spun, forged, pressed or stamped, and when so worked is greatly improved in strength and ductility. M.V. "C" machines easily and is easily welded. WHB(2)

Hiduminium R R Alloys. **(Les alliages Hiduminium R R.)** *Aciers Speciaux, Métaux et Alliages*, Vol. 6, Mar. 1931, pages 126–128.

Hiduminium alloys comprise 4 Al base alloys in which Ti plays an important part. Ti acts as catalyzer and homogenizer. Its physical properties are: specific gravity, 2.7–2.75; heat conductivity, 0.40 C.G.S.; coefficient of dilation, 0.000022/C.°; melting point, 635° C.; shrinkage in casting, 1.25%. The chemical composition is Cu, 0.50–5.0%; Ni, 0.20–2.50%; Mg, 0.04–5.0%; Fe, 0.50–1.80%; Ti, 0.04–0.60; Si, 0.20–5.0%; Al, balance. The mechanical properties of these alloys are greatly improved after heating for 8–20 hrs. at 155–175° C. GTM(2)

A New Aluminum Alloy. T. W. Bossert & J. A. Nock (Aluminum Co. of America). *Metals & Alloys*, Vol. 2, Oct. 1931, pages 238–239.

The authors describe a new Al alloy containing 1% each of Mn and Mg which exhibits excellent resistance to atmospheric corrosion and workability coupled with high strength which has not been previously attained in a corrosion resistant Al alloy. WLC(2)

Forging of Light Metals. Duralumin. **(Les Forges des Métaux legers Forgeage et Métricage du Duraluminum aux Forges de Bologne.)** A. Vella-Ferrand. *Aciers Speciaux, Métaux et Alliages*, Vol. 6, May 1931, pages 243–250; *Revue de l'Aluminum*, No. 40, Nov.–Dec. 1930, pages 1268–1274.

Heat treatment, forging and testing of duralumin type alloys are discussed. The characteristics and composition of the L.2R (duralumin) alloy, which is worked in a forging plant in Bologne, are as follows:

3.5–4.0% Cu	Tensile strength	57,000 lb./in.²
0.5% Mg	Elastic limit	34,200 lb./in.²
0.5–1.0% Mn	Elongation	16%
95% Al	Melting point	640° C.
traces of Si and Fe

Characteristics and Properties of Monel Metal. *Metallurgia*, Vol. 5, Nov. 1931, pages 23–25.

A general discussion of the properties of Monel. Includes a list of mechanical properties and directions for casting and working. JLG(2)

Alloys of Copper—Brasses, Bronzes and Other Materials of Electrical Interest. J. Bradley. *Electrician*, Vol. 107, Nov. 13, 1931, pages 650–653.

An article dealing with alloys in which ingredients other than Cu cannot be regarded as impurities. The alloys discussed are: brass, bronze, phosphor-bronze, gun metal, Al-bronze, Cd-Cu, Mn-bronze or brass, nickel silver and constantan. Tensile strength, yield points and elongation % are given for several of these alloys at various temperatures. WHB(2)

The Beryllium Bronzes. **(Les bronzes an Beryllium.)** *Cuivre & Laiton*, Vol. 4, July 30, 1931, pages 337–340.

A short review of the chemistry and physics of Be. Be is an extremely strong deoxidizing agent and, especially for Cu, preferable to P. Moreover, the density of Cu as well as its electric conductivity are but very little reduced by the addition of Be; an amount of 0.02–0.03% gives a conductivity of 55–56. The metal is then perfectly homogeneous and has a tensile strength of 18–20 kg.–mm.² The Be bronzes usually used contain up to 10% Be, it is so easily poured, the cast metal has an elongation of 36%. It can be rolled with contents up to 3% Be. This bronze shows even better qualities than Sn or Al bronzes. Heat treatment will improve Be Bronze; several methods are described for bronzes of various amounts of Be. Bronze with 2–5% Be, which is not heat treated, has a Brinell hardness of 100 which by proper heat treatment can be increased to 400. Be bronzes have a greater corrosion resistance than steel. The electric conductivity of a 2.5% bronze is about 17–19, while the heat conductivity is about 4/10 that of electrolytic Cu. A bronze of 0.9–1.5% Be seems to give an excellent antifriction metal. In spite of the comparative novelty of this alloy, the experiments have shown an extreme usefulness in many fields. Ha(2)

PROPERTIES OF FERROUS ALLOYS (3)

Research Improves Quality of Electric Steel. F. A. Melmoth. *Foundry*, Vol. 59, Aug. 15, 1931, pages 28–31.

Abstract of a paper read at the Chicago meeting of the American Foundrymen's Association. Deals with the tests conducted to determine the causes of certain abnormalities in electric furnace steel. In cast condition, the open-hearth and electric materials are practically identical in tensile strength, yield point, elongation and reduction. Quenching has a marked influence on the tensile and yield points of both materials. Possible controlling causes of the pressure of abnormal structure might arise from one or more of the following: higher temperature in electric steel; existence of non-metallic impurities; some intensely localized high temperature during manufacture. Furnace practice was also studied. To arrive at possible variations of manipulation and conditions in the electric and open-hearth steel manufacture, each step of the process is recorded. Careful observations of difficult castings liable to hot-cracking has indicated a marked reduction in hot-cracking trouble in case of more controlled electric steel. VSP(3)

The Properties of Malleable Casting and Its Application in the Construction of Automobiles. (Die Eigenschaften von Temperguss und seine Verwendung im Automobilbau.) F. Rubensdoerffer & H. Mueller. *Automobiltechnische Zeitschrift*, Vol. 34, June 10, 1931, pages 385–387; June 20, 1931, pages 408–410.

By means of the iron-carbon diagram, the advantages of malleable casting are explained, as also the good pouring quality in connection with great toughness. Process of production, analysis of different qualities, microphotographs of structure and mechanical properties are described. Numerical values and methods of machining are added. Part 2. From comparative tests with different cast materials, the authors conclude that malleable cast iron (especially white castings) is the best material for highly stressed parts with thin walls. It offers, in the construction of automobiles, the greatest economy and the greatest safety of operation. Ha(3)

Characteristics of Alloyed Cast Iron. F. W. Shipley (Caterpillar Tractor Co.). *American Society for Steel Treating, Preprint* No. 25, 1931, 19 pages.

Paper read and discussed before the Boston Convention of the Society in Sept. 1931. The use of Ni and Cr as alloys in cast iron is discussed and the benefits to be obtained in the uniformity and increased properties are described. WLC(3)

The Precipitation Hardening of Iron by Titanium. (Ueber die Ausscheidungshärtung des Eisens durch Titan.) R. Wasmuht. *Krupp'sche Monatshefte*, Vol. 12, July 1931, pages 159–178.

It has been discovered that Ti is especially capable of producing the so-called "precipitation hardening" in iron which is due to a dissolving and precipitation process of a second, restrictedly soluble phase. This process produces very great hardness, according to the content of Ti. For the commercial percentages up to 3% Ti, the addition of a third element, Si, Ni or others, is necessary to obtain this hardening effect. The changes in hardness, in electrical and magnetic properties of Fe-Ti alloys which have been quenched at annealing confirm the opinion that the precipitation hardening corresponds to the refining of duralumin. The very comprehensive tests which were made to elucidate all the influences of other alloying elements, of annealing and quenching temperatures, cooling velocities are described in detail and the results are reproduced in tables and curves. 14 references. Growth and Scale Resisting Cast Irons. F. K. Neath. *Bulletin British Cast Iron Research Association*, No. 23, Apr. 1931, pages 364–366; *Iron and Steel of Canada*, Vol. 14, June 1931, pages 95, 101.

A review of the development and present state in the production of a cast iron that does not show growth or scaling has led to the following basic conditions: (1) Since it is scarcely possible to prevent carbide decomposition on repeated heatings, an Fe should contain little or no pearlite from the start. (2) Since any transformation tends to loosen the structure because of volume changes and consequently to promote internal oxidation, such transformation within the working temperatures should be avoided. (3) Since coarse graphite tends to promote penetration of gases, the graphite should be as fine as possible. (4) The metallic matrix must be mechanically dense and must, of itself, resist oxidation and must contain no included gases. Tests of some recent German investigations are briefly described and a few figures on mechanical properties are given. Ha(3)

The Wear of Cast Iron. F. K. Neath. *Bulletin British Cast Iron Research Association*, Vol. 3, July 1931, No. 1, pages 10–13.

Better Results Obtained from Gears; Change of Treatment Proves Successful. *Edgar Allen News*, Vol. 10, Oct. 1931, pages 976–977.

A set of gears of case hardened steel showed a much longer life than a set of other gears running under the same conditions in a motor truck. The method of heat treating was the following: the steel was held for $3^1/_2$ hrs. at 875° C. and dipped at 880° C., requenched at 770° C. Ha(3)

Gray Iron Possesses Valuable Engineering Properties. Part XII. *Foundry*, Vol. 59, Jan. 1, 1931, pages 61–64, 78; Feb. 1, 1931, pages 92–94.

These installments describe the reasons for growth of cast iron. The method of measuring the growth with a dilatometer is explained and tables of expansion and growth coefficients are given. Ha(3)

Boiler Steels and Other Soft Steels. *Boiler Maker*, Vol. 31, July 1931, pages 184–186.

A brief review of the elements which make up desirable qualities of boiler steels: C, Mn, Si and their amounts. The welding qualities and the methods of welding and testing are discussed. Ha(3)

Influence of Ingot Section on the Properties of Forged or Rolled Steel. (Contribution a l'etude de l'influence de la section du lingot sur les propriétés mécaniques des barres forgées ou laminées en acier.) A. Portevin, M. Prétet & M. Jolivet. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 135–147. 29 figures.

Includes discussion. See *Metals & Alloys*, Vol. 2, Nov. 1931, page 243. HWG(3)

Some Recent Developments in Corrosion-Resisting Steels. J. H. G. Monypenny. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 201–215.

General discussion of stainless and austenitic stainless steels, with emphasis on need for correct heat-treatment. Failures due to intergranular attack are cited. HWG(3)

Tubing of Various Sizes and Alloys. G. P. McNiff (National Tube Co.). *Metal Progress*, Vol. 19, June 1931, pages 60–65, 83.

The author shows that seamless tube process is not limited to the composition range of other tube processes. Effect of wall thickness on the properties of carbon steel seamless tubing are discussed. Alloy steels, medium manganese, 18 Cr-8 Ni, and 6% Cr, are discussed. Physical properties and applications of these compositions are given. WLC(3)

Iron Castings with Eutectic Structure. (Eisengussstücke mit eutektischen Gefüge.) B. Osann. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, May 8, 1931, pages 373–380.

The author maintains that good castings have always had eutectic structure but it was not recognized because the conceptions of eutectic and eutectic structure have so far not been defined sharply enough. He shows a way to produce this structure with certainty by properly adapting the amount of Si to the content of C which is desired. The eutectic structure also offers the best machinability and gives a good clean surface. From the tests, a formula is developed, by means of which the tensile strength can be calculated from the chemical analysis. The calculated values agree very well with the results of tests. Ha(3)

Properties of Killed and Rimmed Steel. (Eigenschaften beruhigt und unberuhigt vergossenen Stahls.) W. Oertel & A. Schepers. *Stahl und Eisen*, Vol. 51, June 4, 1931, pages 710–715.

The differences of blowholes and segregations of killed and rimmed steel were studied by microscopic examination and chemical analysis. The change of the physical properties between top and bottom, edge and core was determined for billets (70 mm.^{2}) as well as for finished round bars of 40 mm. diameter and 20 mm. diameter, respectively. In annealing, or recrystallizing, the grain of the rimmed steel grows more rapidly than that of the killed steel. There are also differences as to mechanical and magnetic aging. The rimmed steel seems to tend to aging to a smaller extent than the killed steel. GN(3)

The Growth of Cast Iron under Tension Stress. (Das Wachsen von Gusseisen under Zugbeanspruchung.) E. Piwowarsky & O. Bornhofen. *Archiv für Eisenhüttenwesen*, Vol. 5, Sept. 1931, pages 163–166; *Iron & Coal Trades Review*, Vol. 123, Nov. 6, 1931, page 697; *Foundry Trade Journal*, Vol. 45, Nov. 1931, page 306.

Whereas cast iron in application may show changes of volume even at temperatures above 200° C., laboratory tests showed practically no changes of volume up to 550° C. This was supposed to be due to oscillations cast iron structures and machinery parts are subjected to. The investigation was undertaken to elucidate the above assumption. 6 different cast irons were tested and the effect of an increased load (1 kg./mm.^{2}, 2 kg./mm.^{2}, 3 kg./mm.^{2} and 5 kg./mm.^{2}) upon the elongation was studied in dependence upon the time. The results indicate that (1) the temperature of the beginning growth of cast iron is not essentially decreased when the cast iron is subjected to a tension load; (2) a static elongation is observed at temperatures up to about 500° C. This elongation, however, is not simply indicative of the possible growth; (3) volume changes occur at temperatures above 500° C., which indicate growth. Cast irons which had become completely ferritic by annealing in vacuum show, when subjected to a tension load in vacuum, volume changes independent of the chemical composition. The size of these volume changes are in accordance with the volume changes of steel at the corresponding temperatures. A short time growth test is proposed as follows: A 20 hr. heating at 650° C. and a load of 1 kg./mm.^{2} The extension found with this load and time shall be indicative of the growth. Ha+GN(3)

Investigation of the Heat Sensibility of Low Carbon Steel. (Untersuchung der Ueberhitzungsempfindlichkeit von niedriggekohltem Flussstahl.) E. Pohl, E. Krieger & F. Sauerwald. *Stahl und Eisen*, Vol. 51, Mar. 12, 1931, pages 324–326.

Electrolytic iron, low C steel sheets and one low C-Mo steel sheet were used for the experiments. The sheet samples were heated for one hr. and 5 hrs. at temperatures of 950°, 1000°, 1050°, 1100°, 1150°, 1200°, 1250°, 1300°, 1350° and 1400° C. (for one hr. only) and cooled in air. The Mo steel was subjected only to the 5 hrs. heating. After cooling, the grain size was determined and plotted in diagrams. In electrolytic iron, burning and oxidation starts at 1300° and the heating at 1150° C. for the 5 hrs. heating. The corresponding temperatures for the low carbon steel are: 1350° (1 hr.) and 1250° (5 hrs.). In the Mo steel, burning is observed at 1300° C. Material with a larger grain size is less resistant against burning than one with a fine grain. GN(3)

The Practical Application of New Values for the Judging of Cast Iron. (Ueber die praktische Anwendung neuer Wertbegriffe für die Beurteilung von Gusseisen.) Hans Pinsl. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Apr. 1931, pages 334–339; May 1, 1931, 357–363.

For judging the quality of cast iron, Thum and Ude had suggested the use of the ratio σ_B/f = bending strength/deflection, while Meyersberg proposes the bending number 100 × deflection/bending strength $= \dfrac{f \times 100}{\sigma_B}$ and tensile strength × bending number $= \sigma_B \times f \times 100/\sigma_B' = \sigma_B \times Z_f$ = bending product. This latter formula is, however, not intended to give any insight into the texture. The lines of equal bending products are called isoflexes. The formulas were determined on 5 kinds of iron; the relation σ_B/f for the formation of graphite was corroborated. The isoflex-diagram corresponds also to the views obtained with the first named method and offers, therefore, a reliable measure for the quality with regard to bending and tensile strength. If location of the isoflexes is reduced to a standard sample, each kind of casting will then give its own characteristic isoflex-diagram. Ha(3)

High Strength Malleable. (La malléable à haute résistance.) E. Piwowarsky. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 879–884. 14 figures.

General résumé. Average properties of black heart malleable made in different types of furnaces are:

Furnace	Tensile strength lbs./in.^{2}	Elongation % in $2^1/_2$ in.
Cupola	54,000	10.9
Oil Furnace	52,000	12.0
Open Hearth	57,000	11.1
Brackelsberg	61,500	18.1

The General Electric method for rapid annealing is mentioned. The author gives a curve to show that instead of 5 days on the usual cycle, by heating first to about 1075° C. then cooling to about 750° C., and running the temperature up and down from 750° to 770° C. several times, the process can be completed in 1 or 2 days, according to the size of the furnace. Cr alone hinders graphitization. Ni favors it, but Ni alone does not produce an improved malleable. The combination of $2^1/_2$% Ni and $^1/_2$% Cr in alloy heated to 975° C. (for 3 hrs. against 1 hr. for the unalloyed malleable) raised the tensile strength from 88,000–92,000 to 100,000–128,000 lbs./in.^{2}, and dropped the elongation from 2–4% to $^1/_2$–1%. HWG(3)

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Some Properties of Protective Films on Metals. Ernest S. Hedges. *Journal Society Chemical Industry*, Vol. 50, Jan. 9, 1931, pages 21-25.

The oxidation of metals in the air is determined by 3 factors: (1) the chemical affinity for O, (2) the volatility of the metal and (3) the physical properties of the oxide. In aqueous solutions, corrosion is determined by the solution tension of the metal and the physical and chemical properties of the product. Given a solution tension such that the reaction will start, how far it will proceed will depend to a large extent on the solubility of the product. If readily soluble, the reaction should continue rapidly; if insoluble it may or may not allow further corrosion, depending on whether its physical properties are such as lead to a sufficiently protective film. When a metal is made the anode of an electrolytic cell, it may exhibit more than one type of behavior. (1) It may be unattacked by the liberated ions and lead to the evolution of O. (2) A film of insoluble and poorly-conducting material, practically preventing further passage of current, may form on the metal. (3) The metal may dissolve continuously to form a salt. (4) The metal may dissolve smoothly at low current densities, while with increase of current a film may form. When (4) occurs, the current passing falls and the potential of the anode rises on formation of the film; dissolution of the metal may continue at a slower rate, giving perhaps ions of higher valency, or the metal may become passive, scarcely dissolving at all, while O is freely evolved. Many examples of the factors enumerated for the various exposures of metals are given. VVK(4)

Faraday's Views on Passivity in the Light of Recent Research. Ernest S. Hedges. *Journal Society Chemical Industry*, Vol. 50, Sept. 11, 1931, pages 750-751.

Faraday in 1836 discussed the phenomenon of passivity ascribing it to the production of an oxide film. His discussion contains the fundamental views accepted today although he lacked the experimental substantiation such as the actual separation of the oxide film, etc. The author also gives an excellent brief historical review of passivity. VVK(4)

Correlation of Certain Soil Characteristics with Pipe-Line Corrosion. I. A. Denison. *Bureau of Standards Journal of Research*, Vol. 7, Oct. 1931, pages 631-642; *Oil & Gas Journal*, Vol. 29, June 5, 1930, page T-200.

Corrosion experienced in the operation of a group of pipe lines in Ohio was found to be related to the kinds of soil which occur along a 32-mile section of the lines. Soils of the Brookston series in this area are non-corrosive. Soils of the Nappanee series proved to be corrosive wherever they occurred. The Wauseon soils occurring on slopes or slight ridges were observed to be corrosive. Other sandy and sandy-loam soils not underlain by glacial material apparently have little corrosive action. A satisfactory correlation was found to obtain between the exchangeable H present in the soils and corrosiveness as indicated by the quantity of pipe replaced in 1000-foot intervals. The hydrogen ion concentration of soil samples in normal potassium chloride solution is a fairly satisfactory index to the corrosiveness of the soils studied except in the case of slightly buffered sands. Both methods, however, tend to exaggerate the corrosiveness of well-drained sandy soils. An accelerated laboratory test of soil corrosiveness involving the corrosion of a steel disk in contact with moist soil is described. The results obtained paralleled the quantity of pipe replacements fairly closely in the case of heavy soils. The degree of corrosiveness indicated by the test is influenced by the acidity, texture and probably by the structure of the soils studied. Since only a qualitative study of the factors influencing the test has been made, the test cannot at this time be considered a reliable index of soil corrosiveness except in the case of soils similar to those tested. The methods described for identifying corrosive soils which involve determinations of acidity are probably most reliable in the case of related soils which differ from one another chiefly in their contents of exchangeable H. The data obtained from the tests are probably insufficient to indicate the relative corrosiveness of soils having widely different physical and chemical characteristics. VVK+WAT(4)

Prevention of Valve-Seat Erosion. Edward M. Getzoff. *S.A.E. Journal*, Vol. 29, Oct. 1931, pages 332-335.

A theory for the cause of a thin spotty deposit or pick-up on the valve seat that accelerates erosion is advanced, and this deposit is said to be absent on valve seats made of non-ferrous metals. Al bronze gives satisfactory results but is difficult to secure to cast iron cylinder-blocks because of its greater coefficient of expansion. Several partially successful methods of securing Al-bronze rings to cast iron are shown. A method that is applicable to one alloy which has reduced erosion under the most severe operating condition to such an extent that it is almost negligible is described. (4)

Methods for Testing the Corrosion Resistance of Light Metal Alloy Sheets. Martin Abraham. *Metal Industry*, London, Vol. 39, July 17, 1931, pages 51-53; July 24, 1931, pages 77-79.

Condensed from lecture of Erich K. O. Schmidt, Dr. Ing. before Deutsche Gesellschaft für Metallkunde. Alterations in mechanical properties and microstructure should be taken as main indications of corrosion resistance of a metal. Testing methods used by Deutsche Versuchsanstalt für Luftfahrt are (1) stirring method where the specimen is completely immersed in 3% NaCl solution to which may be added 0.1% H_2O_2 if sheet is Al coated; (2) dipping method where specimen is dipped for 2 min. every hr. in 20% NaCl solution; (3) spraying where specimen is subject to NaCl spray for 10 min. every hr. The thickness of the uncorroded specimen is used as basis for computations. Bend tests and alterations in Erichsen values are sometimes used as additional means of comparison of corrosion resistance of different materials. PRK(4)

Chemical Methods of Treatment of Metals and Alloys to Prevent Corrosion. (Les méthodes purement chimiques le traitement des métaux et alliages contre la corrosion.) J. Cournot & J. Bary. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liège, June 1930, pages 493-498.

Brief mention is made of methods of blueing steel and coloring various alloys. Parkerising and other phosphate treatments are dealt with in more detail. "Protalization," a process of producing an oxide film on Al and its alloys and rendering the oxide coating insoluble, is mentioned but not clearly described. See also *Metals & Alloys*, Vol. 2, Jan. 1931, page 3. HWG(4)

Ammonia to Combat Corrosion to Rerun Unit. J. C. Albright. *Refiner & Natural Gas Manufacturer*, Vol. 10, Aug. 1931, pages 71-74.

Ammonia is utilized to give alkaline reaction to the condensate recovered from the pressure distillate processed through it. (4)

On the Attack of the More Common Metals by Phosphoric Acid Solutions. (Sur l'attaque des metaux usuels par les solutions phosphoriques.) A. Portevin & A. Sanfourche. *Comptes Rendus*, Vol. 192, June 15, 1931, pages 1563-1565.

In an article accompanied by 1 diagram, representing the loss in weight in mm./cm.^{2} during a period at most 250 hours, the authors present results of tests on the corrosion of Al, Sb, Bi, Cd, Cu, Fe, Pb, Mg, Ni, Ag, Sn and Zn in phosphoric acid of three different concentrations. The authors arrange the metals in three groups—those readily attacked (of which Mg and Zn are examples), those practically unaffected by the acid (such as Bi and Ag), and those which are affected intermediately in greater or lesser degree. OWE(4)

A Corrosion Tester for Pressure Vessels. Cloyd M. Chapman. *Instruments*, Vol. 4, Oct. 1931, page 527.

A device for testing corrosive action in a pressure vessel is shown, by which a sample of metal in either wire or block form can be pushed into the vessel through a nipple and withdrawn after the proper interval of time without in any way interfering with the operation going on in the vessel. An aluminum yoke with a large hand wheel is attached around a stuffing box. A spindle of stainless steel, with double-lead threads, moved through the stuffing box by turning the hand wheel, carries the sample to be tested for corrodibility at the other end, attached to a porcelain spool. When the sample is drawn back out of the pressure vessel at the end of a test, a gate valve forming part of the instrument, capable of withstanding 400 lb. pressure, is closed. The test metal block or wire can then be taken off and examined. A sample in the form of very fine wire gives returns in the shortest time. Wire of Bessemer steel, pure iron, and some of the alloys can be had in sizes down to 0.003 in. If the sample is in block form, one or more surfaces should be polished. The polish should not be so high as to inhibit corrosion. Three $^1/_2$ in. blocks can be tested at once by insulating with nonmetallic washers and bushing, or more if they are enough smaller. The porcelain spool has 4 sets of notches so that 4 wires may be wound on and tested at once; and there is room for 2 spools to be put on the spindle at once. A pocket microscope giving a magnification of 40 or 50 diameters is very convenient for examining the corroded samples. (4)

The Effect of Hydrogen Ion Concentration on the Corrosion of Tin. J. M. Bryan. *Transactions Faraday Society*, Vol. 27, Sept. 1931, pages 606-620.

In the absence of air, Sn suffers negligible corrosion in citric acid, but in the presence of O, corrosion reaches a maximum at a pH 3.1. Ferrous citrate additions accelerate corrosion. Ferric citrate, even in the absence of O, causes corrosion of Sn in 0.5% citric acid solution. 20 references. PRK(4)

Quay Wall Design and Construction. Louis Beaudry. *Engineering Journal*, Vol. 14, July 1931, pages 394-397.

Various types of quay walls suitable for the severe climatic conditions of eastern Canada are described. Some steel sheet piling, installed 16 yrs. ago by the Harbor Commissioners of Quebec was corroded as follows. The portion of pile above high water and exposed to the atmosphere at all times was dark brown in color and uniformly pitted. The portion of pile submerged at nearly all times was corroded and showed some pocking. The portion of pile buried in the sand showed some pocking at the level of the ground surface but a few ins. below this was in a good state of preservation. The author states, "Although no definite conclusions may be drawn from these isolated tests, the sixteen years of exposure justifies us in saying that the fears entertained as to premature deterioration of the steel wall through corrosion were not well founded. The results of the tests seem also to confirm the statements and findings of other engineers who have studied steel structures which have been exposed for even longer periods. Therefore, we may safely come to the following conclusion, 'steel that is buried in sand or ground, or is submerged in water, is less exposed to damage through corrosion than when exposed to the air.' This conclusion is doubly valuable since the portion of the steel wall which is most subject to corrosion is that portion which can be periodically inspected." Steel quay walls designed for a life of over 40 yrs. may be protected as follows. (a) Provide a cap of reinforced concrete on the top of the wall and fill the space between the upper and the lower wallings so that water will not run directly on the piling. (b) Cover all the surfaces of the steel to be buried with a heavy coating of paint, free from acid and oil, since the acid may cause corrosion and the oil may be saponified within a short period of time. (c) Paint the piles before driving. (d) Use heavier connections on wallings and anchors because when 2 dissimilar metals are placed in contact with each other, riveted or bolted together, there is a tendency for one of the metals to be preserved from corrosion at the expense of the other, which will corrode much more readily in such a case. (e) Use anticorrosive steel such as cupiferous, Ni and Cr steels. VVK(4)

Corrosion Resisting Coatings for Duralumin. H. A. Gardner. *Metal Cleaning & Finishing*, Vol. 2, Dec. 1930, pages 1065-1066.

The Colloid Theory of the Corrosion of Iron and Steel. J. Newton Friend. *Transactions Faraday Society*, Vol. 27, Sept. 1931, pages 595-596.

In rapidly moving aerated water, Fe passes slowly into solution and the iron hydroxide is swept away. Under stationary conditions, the Fe passes into solution and the ferrous hydroxide clings to portions of the metallic surface, partially screening it from O and inducing anodic corrosion. Includes discussion. PRK(4)

Formation of Ferrite in the Rusting of Iron. (Bildung von Ferrit während des Rostens von Eisen.) C. Carius. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 197, Apr. 30, 1931, pages 254-256.

Observations on the work by A. Krause and J. Tulecki. Ferrous ferrite corresponding to the formula $Fe(FeO_2)_2$ was prepared by electrolysis of NaCl solution with electrolytic Fe as anode. The black product formed was submitted to X-ray examination and showed a few lines belonging to the magnetite lattice as well as a few faint lines due to the admixture of other oxides. The formation of ferrite is explained as follows: in the acid O-containing solution Fe^{++} ions separated at the anode are completely oxidized to Fe_2O_3, which is positively charged. With continuing electrolysis the pH falls, the Fe_2O_3 becomes negatively charged, Fe^{++} ions are no longer oxidized to Fe_2O_3, and the formation of $Fe(FeO_2)_2$ occurs. Rust which is formed by corrosion of Fe in weakly acidified distilled water shows the same lines on X-ray examination. The X-ray diagram of rust formed by corrosion of Fe in water with pH between 5.5 and 6.5 shows the lines corresponding to γ-FeOOH. (4)

Methods and Apparatus for Corrosion Testing of Metals. (Ueber Methoden und Apparate zur Korrosionsprüfung von Metallen.) G. Gollnow. *Chemische Fabrik*, Vol. 4, Aug. 5, 1931, pages 326-328; 341-342.

Corrosion of Various Alloys in Solutions of Phosphoric Acid. (Attaque de divers alliages par les solutions phosphoriques.) A. Sanfourche & A. Portevin. *Comptes Rendus*, Vol. 193, July 6, 1931, pages 53–55.

The authors continue a report of their investigations of the corrosion of metals by phosphoric acid solutions (C.R.192, 1931, p. 1563) by describing an investigation of a series of alloys including: Alpax, containing 13% silicon; Duralumin, containing 3.8% copper; 0.5% magnesium, 0.4% silicon and 0.4% manganese; brasses, containing 60 and 65% copper; bronze, containing 9% tin; cupro-nickel, containing 84, 57 and 27% copper; nickel-silvers, containing 62% copper and 12% nickel, and 65% copper and 5.7% nickel; antimonial lead (7% Sb); and a series of steels of different compositions, including some stainless steels of austenitic and martensitic structure. The results of the tests showed that the alloys of aluminium were readily attacked (losses of 0.0002–0.0005 g./cm.^{2}/hr.), that the alloys of copper were less readily corroded (losses, varying according to the alloy, of 0.0002–0.0004 g./cm.^{2}/hr. in 52° B acid, and from 0.0001 to 0.0002 g./cm.^{2}/hr. in acid of 30° B). It was noted that antimonial lead did not show the same resistance to attack that was observed in the case of pure lead. The results obtained on the steels are shown graphically. As a result of analysis of the corroding media subsequent to the tests, it was discovered that in those steels which were rapidly corroded, the chromium was attacked more readily than the iron, the nickel less than either. In the cupro-nickels the two constituents were dissolved in about the same proportions; the same was true for the brasses, but in the bronze the tin was attacked more than the copper. At the conclusion of the paper reference is made to a series of tests which have been conducted on a group of ferro-alloys, the results of which indicated that only ferro-chromium and ferro-silicon can be considered resistant to the attack of phosphoric acid solutions. Hydrogen Sulphide Corrosion in Natural Gas Engines. V. L. Maleev. *Power*, Vol. 74, July 28, 1931, pages 127–128.

Gas containing 5% H_2S was quite corrosive until freed from H_2O. Then it could be used without difficulty. (4)

Electrical Conductivity and Tensile Properties of Light Magnesium-Aluminum Alloys as Affected by Atmospheric Exposure. E. Wilson. *Journal Institution Electrical Engineers*, Vol. 69, Dec. 1930, pages 89–94; *Journal Society Chemical Industry*, Vol. 50, March 6, 1931, page 205.

Comparative atmospheric corrosion tests have been made on stressed conductor wires of high-purity aluminum, aldrey, duralumin and a 0.75% nickel-aluminum alloy. The change in resistance with time was least with the nickel alloy and greatest with duralumin; after two years the ratio R_0/R_t was 0.96 for the nickel alloy, 0.93 for aluminum, 0.90 for aldrey and 0.85 for duralumin. Intercrystalline corrosion in the duralumin was very marked, but occurred to only a slight extent in aldrey and not at all in the nickel alloy or aluminum. The loss in weight and the increase in specific resistance were the same for the nickel alloy after exposure for 24 years as for aldrey after exposure for 1.5 years. All four conductors showed an average loss of 7.5% in the breaking load after 9 months, but there was a tendency for the more tightly stressed wires to suffer a smaller decrease in strength than that of similar wire under corrosion was in the elongation, especially in the case of duralumin, which after 8 years failed to show any elongation in the tensile test. The Corrosion and Protection of Magnesium and Magnesium-Base Alloys. L. Whitby. *Industrial Chemist*, Vol. 7, May 1931, pages 203–206.

44 references. Article is subtitled, "A Survey of Available Information." Attack by aqueous solutions usually results in severe pitting and does not seem to be subject to intercrystalline corrosion. Need for work on corrosion fatigue of Mg alloys cited. Oil and motor fuels containing organic acids or ethyl alcohol are detrimental. Relation between corrosion and microstructure briefly discussed. Effect of certain alloying elements on the corrosion of Mg is discussed. Mn is added to most Mg-base alloys to restrain corrosion. Methods of protection named and briefly discussed are, (1) alloying, (2) electrolytic methods, (3) chemical dipping methods, and (4) paint coatings. RAW(4)

The Development of Railway Water Supply Practice. C. R. Knowles (Illinois Central System). *Journal American Water Works Association*, Vol. 23, Apr. 1931, pages 481–488.

A general account of the various agencies, societies, etc. working on the problem of railway water supplies and corrosion. VVK(4)

Corrosion Prevention. I. By Metal Composition. II. By Protective Coatings. W. S. Johnston. *Power*, Vol. 74, July 28, 1931, pages 121–123; Aug. 4, 1931, pages 155–157.

Loss through corrosion of iron and steel is about 2%/yr. The author discusses common types of corrosion, the use of non-corrosive alloys and of protective coatings. (4)

Corrosion in Ballast Tanks and Tankers. Correspondence from F. C. Martin, Birkenhead, England. *Metal Progress*, Vol. 20, Nov. 1931, page 79.

The attack of tanks for carrying liquid cargoes by the liquids themselves and by sea water that may be used as ballast on return trip is discussed. WLC(4)

The Nature of the Covering Layers Appearing in the Anodic Passivity of Iron in Solutions Containing Sulphate Ions. (Ueber die Natur der Deckschichten, welche bei anodischer Passivierung von Eisen in sulfationhaltigen Lösungen auftreten.) W. J. Müller & W. Machu. *Zeitschrift für physikalische Chemie*, Bodenstein Festband, 1931, pages 687–703.

The authors combine the measurement of the passification time and the observation on the passification process by means of the polarization reflexion microscope and found the following possible types of surface layers causing the passivity of Fe in solutions containing sulphate ions: (1) the natural oxide layer as produced by air; (2) a layer consisting of $FeSO_4 \cdot 7H_2O$ which is found in all acid solutions above 0.5 *N*; (3) an oxide film, not identical with the "natural oxide layer," is formed with potentials over 2 volts. The total SO_4^{--} concentration plays the dominating role, since the same passification occurs in 0.1 *N* H_2SO_4 as well as in 0.1 *N* Na_2SO_4; (4) a porous layer of a basic salt which is formed in diluted SO_4^{--} solutions. The Wear of Metals. Louis Jordan. *Mechanical Engineering*, Vol. 35, Sept. 1931, pages 644–651.

The present paper must at once disclaim any pretense of being the desired adequate presentation of a field at once so broad and so little understood. It attempts only to make some tentative definitions and classifications of various types of wear of metals; to offer a few comments on the possible mechanisms of wear; to indicate rather sketchily the importance of the part played by the wear of metals in engineering design and service; to recall various means that are employed for the lessening of or protection against wear; to discuss the extent to which the testing or research laboratory is able to predict from accelerated tests the relative wear resistance of metals; and, finally, prompted by a suggestion that has been made a number of times both verbally and in the literature, to raise the question as to whether the problem of the wear of metals is of such a nature, magnitude and importance that any formal organization and co-ordination of interested research agencies might bring about more notable progress in furthering knowledge in this field. Further Investigations on the Structure of Phosphate Slags and Its Relation to the Solubility in Citric Acid. (Weitere Untersuchungen über das Kleingefüge verschieden vorbehandelter Phosphatschlacken und seinen Zusammenhang mit der Zitronensäurelöslichkeit.) H. SCHNEIDERHÖHN. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 13, No. 7, 1931, *Report* 177, pages 109–120; *Archiv für Eisenhüttenwesen*, Vol. 5, July 1931, pages 9–16; *Stahl und Eisen*, Vol. 51, July 16, 1931, pages 917–918.

Report No. 209 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Thomas slags with additions of sand or fluorspar or both together were subjected to various cooling conditions and microscopically examined. The addition of fluorspar causes the disintegration of the silico carnotite ($5CaO \cdot P_2O_5 \cdot SiO_2$) into apatite and calcium ortho silicate. Since silico carnotite has a high solubility in citric acid and apatite is insoluble in this acid, an explanation is found for the poor solubility in citric acid of the slags with additions of fluorspar. Further investigations were made with finished and unfinished open-hearth slags. In this case, a high solubility in citric acid is also due to the presence of silico carnotite. Beside this phosphate, 2 more phosphates of unknown character were microscopically established. The phosphates possess a much smaller solubility in citric acid than the silico carnotite. By adding fluorspar to the open-hearth slags, apatite is formed causing the solubility to be further decreased. The following conclusions are drawn: (1) In all phosphate slags, a high solubility in citric acid is due to the presence of silico carnotite. (2) CaO, SiO_2 and P_2O_5 should be present in the relation $5CaO{:}1\ SiO_2{:}1\ P_2O_5$ in order to form silico carnotite. (3) As to chemistry, structure and solubility in citric acid, all phosphate slags should be divided into silico carnotite slags and apatite slags. (4) Only slags with a normal content of CaO and SiO_2 possess a high solubility in citric acid. (5) Conclusions are drawn upon the practical production of phosphate slags with a high solubility in citric acid. GN(5a)

The Solid Solutions of the Copper-Silver System. D. STOCKDALE. *Engineer*, Vol. 151, Mar. 20, 1931, page 328; *Engineering*, Vol. 131, Mar. 20, 1931, page 382.

Abstract of paper read before the Institute of Metals, Mar. 11, 1931. See *Metals & Alloys*, July 1931, page 128. LFM(5a)

The Ternary System Iron–Sulphur–Carbon. (Ueber das ternäre System Eisen–Schwefel–Kohlenstoff.) R. VOGEL & G. RITZAU. *Archiv für Eisenhüttenwesen*, Vol. 4, May 1931, pages 549–556; *Stahl und Eisen*, Vol. 51, June 25, 1931, pages 793–794.

The partial diagram Fe-Fe_3C-FeS was investigated by thermal analysis and microscopic examination. The previous results by H. Hanemann and A. Schildkötter (*Archiv für Eisenhüttenwesen*, Vol. 3, 1929–30, pages 427–435) were confirmed. The ternary diagram shows a miscibility gap in liquid state that can be determined from the temperature-concentration sections without special chemical investigation. A method is described that permits the determination of one branch of the miscibility gap when the other one is known. The field of primary disintegration must be distinguished in the diagram. It starts even before the beginning crystallization and the adjacent concentration field of the secondary and ternary disintegration, respectively. It results from theoretical considerations that iron sulphide in the shape of fine drops is present even far below the C and S concentration of the actual primary crystallization. Only 3 crystal types crystallize: binary solid solutions of Fe and C, cementite and iron sulphide. The ternary eutectic crystallizes at 975° C. with 0.15% C and 31% S. The amount of cementite in the ternary eutectic is very small. The eutectic is chiefly composed of FeS and the binary solid solution of Fe and C. The disintegration of the solid solutions (formation of ferrite and cementite) and the pearlite temperature is not essentially affected by the S content. The C content in meteoric iron may be the reason for the drop-like shape of the troilite. GN(5a)

The Ternary System Iron–Carbon–Vanadium. (Ueber das ternäre System Eisen-Kohlenstoff-Vanadin.) R. VOGEL & E. MARTIN. *Archiv für Eisenhüttenwesen*, Vol. 4, Apr. 1931, pages 487–495; *Stahl und Eisen*, Vol. 51, June 4, 1931, page 715.

The binary diagram Fe-V was established first within the range of the Fe transformations. The α-γ transformation at 1400° C. decreases up to 1.8% V but increases above this concentration. V increases the temperature of the magnetic transformation at 76.8° C. This transformation could be observed up to 25% V. In the partial diagram Fe-V-V_4C_3-Fe_3C, there exists beside V_4C_3 no other vanadium carbides or double carbides. The α-γ transformation extends over the whole range from the system Fe–C to the system V-V_4C_3 and passes through a minimum temperature. A saturated γ-solid solution with 3.4% C and 6.5% V together with Fe_3C and V_4C_3 forms a ternary eutectic at 1095° C. The eutectic composition is 81.6% Fe, 6.2% C, 12% V. The ternary γ-solid solutions decompose during cooling and form a ferrite phase and a carbide phase with a subsequent formation of pearlite. The decomposition of pearlite of C steels is very much retarded by V, even at low concentrations. On the other hand, V_4C_3 is always rapidly precipitated. The reasons for the increase of hardness of C steels by V are as follows: (1) the increase of hardness of the ferrite phase, (2) the effect on the refining of the pearlite, (3) the precipitation of the extremely hard V_4C_3. GN(5a)

The Ternary System Iron–Phosphorus–Sulphur. (Das ternäre System Eisen–Phosphor–Schwefel.) R. VOGEL & O. DE VRIES. *Archiv für Eisenhüttenwesen*, Vol. 4, June 1931, pages 613–620; *Stahl und Eisen*, Vol. 51, Aug. 6, 1931, pages 1006–1007.

The paper covers an investigation of the partial diagram Fe-Fe_3P-FeS and establishes a new diagram. GN(5a)

Structure Investigations of Cast Metals and Alloys. (Gefügenuntersuchungen an gegossenen Metallen und Legierungen.) E. SCHMID. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 10, 1930, pages 26–29.

The importance of the radially crystallized edge zones is pointed out as greatly influencing the workability of the material. The orientation of the crystals in relation to their velocity of growth should be investigated more thoroughly to be able to explain the origin of the radial edge zones. See *Metals & Alloys*, Vol. 1, Nov. 1929, page 245. Ha(5a)

The authors present a system of standard microphotographs to be used for the metallographic control of heat treatments of high C steels. WLC(5a)

A Critical Study of the Origin of the Banded Structure of a Hot-Worked Hypo-Eutectoid Steel. F. C. THOMPSON & R. WILLOWS (Victoria University of Manchester). *Iron & Steel Institute, Advance Copy* No. 13, Sept. 1931, 26 pages.

35 references. The experimental work and the reasons suggested for banding given by other workers is reviewed. Steel samples were oxidized and heated in CO. After this treatment, it was found that banding did not occur immediately below the decarburized layer. It is concluded that banding is caused by differences in O concentration, and is not affected by P or S concentration gradients. Slag inclusions exert an indirect effect, probably due to the oxides in solution around them. JLG(5a)

The Recrystallization. (Die Rekristallisation.) G. TAMMANN. *Zeitschrift für Elektrochemie*, Vol. 37, Aug.–Sept. 1931, pages 429–436.

Under high degrees of deformation, the crystallites of a metallic coating are lengthened by the sliding of their parts on crystallographically defined planes and directions and the parts are fairly well orientated. In this manner, the elastic, physical and chemical properties are changed because of changes in the atoms. The following property changes, among others, take place: (1) In stretching an iron rod, 5–15% of the stretching energy remains as potential energy in the rod and, under heating, the potential energy is transformed into heat at a temperature interval in which the structure of the hard metal has not yet changed noticeably. (2) The galvanic potential is greatly increased by grinding. (3) The color of certain Au-Ag-Cu alloys becomes yellower by rolling. (4) Cold-working shifts the limits of action to higher percentages of the nobler components. (5) Polonium is precipitated faster by hard Ag and Fe than by soft Ag and Fe. (6) Hg moistens Ag and Cu in the hard state much faster than in the soft state. (7) The dissolving velocity of Fe in acids is considerably greater in the hard than in the soft state. (8) The elastic resistance of a soft tungsten wire is increased by drawing to such an extent that this increase in a regular crystal cannot be ascribed solely to a change in the orientation of its crystallites. (9) Precipitations from over-saturated solid solutions take place with greater velocity in the deformed than in the undeformed state and the precipitations accumulate especially at the slide-lines; this is shown by etching with Fry's reagent. (10) Undeformed rock salt turns yellow by radiation with Ra; deformed salt, black. The tests and experiments made to show these conditions of changed states of crystallites in their various stages and the recrystallization are described. 28 references. Ha(5a)

Contributions to the Physics and Metallography of Magnesium. (Beiträge zur Physik und Metallographie des Magnesiums.) E. SCHMID. *Elektrochemische Zeitschrift*, Vol. 37, Aug.–Sept. 1931, pages 447–459.

This is a report of the more recent investigations in the laboratory of the Farbenindustrie A.G. of the physical properties of Mg, the phenomena of plastic deformation and some technically important series of solid solutions of the metal. The physical anisotropy of Mg crystals is explained and the 5 parameters necessary for the characterization of the elastic behavior are determined. The thermal expansion of Mg is almost isotropic. The specific electric resistance of the crystal is given as $\sigma = 3.77 \times 10^{-6}$ ohms/cm., $\sigma\perp = 4.54 \times 10^{-6}$ ohms/cm. The crystallographic characterization of deformations and the dynamic characterization of the basis translation are explained and illustrated by roentgenograms and micrographs. Finally, the formation of α-solid solutions of Al-Mg, Zn-Mg and Mn-Mg are discussed and illustrated and the results of tensile tests are given in the form of curves. 26 references. Ha(5a)

Resistivity of Single Crystal Zinc. E. P. T. TYNDALL & A. G. HOYEM. *Physical Review*, Vol. 38, Aug. 15, 1931, pages 820–827.

Measurements on specific resistance as a function of orientation check the Voigt-Thomson symmetry relation accurately for crystals made from Kahlbaums best Zn. The principal resistivities are: $p_{||} = 6.20^2$ and $p_\perp = 5.86^5 \times 10^{-6}$ ohms/cm.^{3}, with the ratio $p_{||}/p_\perp = 1.057$. For "spectroscopically pure" Zn the majority of the crystals yield consistently the same value of $p_{||}/p_\perp$, with $p_{||}$ and $p_\perp$ each about 0.6% lower than for the Kahlbaum Zn crystals. A few crystals of "S.P." Zn gave anomalous results of a type previously found by Bridgman. The disagreement between the authors' values, particularly the $p_{||}$ and $p_{||}/p_\perp$, and Bridgman's most recent values does not seem explicable in terms of an effort on resistivity of strain, but rather must be ascribed to differences in the crystals caused by some as yet unknown conditions governing the crystal growing process. WAT(5a)

Transformational Characteristics of Iron-Manganese Alloys. HOWARD SCOTT (Westinghouse Elec. & Mfg. Co.). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 435, Sept. 1931, 19 pages.

Transformations were studied by means of a dilatometer. A new transformation occurring in alloys containing between 12 and 20% Mn was detected. In contrast to the A_3 transformation, the new or A_s transformation occurs with an increase in volume on heating and a decrease on cooling. An irreversible contraction on heating was found only in high C alloys that had been cooled rapidly. The effects of various amounts of Ni, Mn and C on the temperature of the beginning of Ar_3 are discussed. 1% Mn is equivalent to 25% Ni and 1% C is equivalent to 18% Ni with respect to the lowering of this temperature. These relationships hold when 5% or more Ni is present, but not so well in the absence of Ni when Ar_3 begins below 300° C. It is suggested that the A_s transformation represents a transformation between the γ-solution and the hexagonal close packed phase designated by Schmidt and Ohman as the epsilon phase. X-ray diffractions did not support this contention. The microstructure was appreciably changed by this transformation, however. The principle of pressure restraint of transformations is discussed. 11 references. JLG(5a)

Influence of Special Elements on the Carbon Content of the Iron-Carbon Eutectoid. EVERETT L. REED (American Sheet and Tin Plate Co.). *American Society for Steel Treating, Preprint* No. 32, 1931, 60 pages, 36 references, 39 micrographs.

Paper read and discussed before the Boston Convention of the Society in Sept. 1931; a condensed report of research conducted as part of the requirements for Doctor of Science degree at Harvard University. The author reports his determinations of the displacements of the eutectoid composition by the addition of increments of 1% of Ni, Mn, Cr, W, Mo, V, Si, Cu, Al, Co, Ti, and U to pure Fe-C alloys of 0.16%, 0.32%, 0.59% and 1.50% C. Melts were made in vacuum and in most cases melted twice. A microscopic analysis of slowly cooled specimens was made and confirmed by determination of the hardening power of the alloy. A study of the segregation in some of the cast specimens is reported. Hypereutectoid Ni and Mn steels were found to be martensitic. Hypereutectoid Cr, W, Mo, and V steels were found to be cementitic. The special elements may be arranged in order of their power to displace the Fe-C eutectoid as V, Mn, Cr, Mo, W, and Ni. Body-centered elements displace the Fe-C equilibrium diagram to the left while face-centered cubic elements, except Ni, displace it to the right. The enlargement or closure of the γ field due to alloys is discussed. Hardness of all steels in the as-cast, annealed, and normalized conditions are reported. A study of spheroidizing in eutectoid steels was made. The effect of the alloys on the critical range is reported. Tensile, Charpy and twisting tests were made on Ni, Cr and Mo steels of eutectoid composition. Mo steel possessed the maximum torsional strength at high temperatures. Cr steel is not strengthened in the blue heat range. WLC(5a)

Thermo Magnetic Analysis and the A_0 Transformation in 0.75% Carbon Steel. R. L. Sanford & G. A. Ellinger (Bureau of Standards). *Preprint* No. 32 for June 1931 meeting, *American Society for Testing Materials*, 11 pages, 5 figures.

In an annealed high carbon steel, a change in magnetization occurs at 150–215° C. (300–420° F.) on heating, usually termed the A_0 transformation, and ascribed to the presence of Fe_3C. A hardened carbon steel shows no trace of A_0. The question arises whether the absence of A_0 proves the absence of Fe_3C in untempered martensitic steel. It has been suggested that the Fe_3C is in too fine a state of sub-division to show A_0. But by progressively spheroidizing the Fe_3C in a 0.75% C, 0.52% Si steel, it was shown that A_0 decreased in intensity and temperature as the size of the Fe_3C particles increased. A_0 occurs in sorbitic steel. It was concluded the absence of A_0 probably indicates absence of carbide, and that untempered martensite probably does not contain Fe_3C. HWG(5a)

The Formation and Decomposition of Cementite. (Sur les conditions de formation et de décomposition de la cémentite.) P. Pingault. *Comptes Rendus*, Vol. 191, Nov. 24, 1930, pages 1007–1008.

Pure cementite, prepared by the action of NaCN upon Fe filings at 650° C., was heated in vacuum at various temperatures and subjected afterward to the attack of HNO_3 (d = 1.2). After 10 hrs. at 1000° C. only faint traces of graphite could be found. After 1 hr. at 1075° C. the cementite was agglomerated and distinct traces of graphite were found. After 1 hr. at 1175° C., the cementite was transformed partly into metallic globules having the microscopic characteristics of gray cast iron and partly into a powder, containing much graphite. Below 1000° C., therefore, the pure cementite may be considered very stable, but as soon as the melting temperature of cast iron is approached, the decomposition of the cementite becomes rapid. In forming cementite from pure Fe and NaCN in the absence of air, it was found that the cementation of the Fe was negligible at a temperature of 600–650° C. and 850–900° C. The same results were obtained in pure and in commercial NaCN. Different results obtained in the presence of air are believed to be due to the carbonizing action of the decomposition products of the NaCN. Soft steel electrodes were immersed in a NaCN bath kept at 650° C. and a current passed through. The effect varies considerably with the current density. After 40 hrs. at 1 amp./$dcm.^2$, the anode was much hardened while the cathode remained unchanged. At 20 amp./$dcm.^2$, there was no hardening of the electrodes, but the anode was corroded. At 60 amp./$dcm.^2$, the loss of weight of the anodes after 15 hrs. amounted to 2.5 gr/$cm.^2$ The powder derived from the decomposed anodes was found to contain 6% C and 2–2.5% O. It consists of cementite detached from the anode on account of the great speed of formation and on account of its fineness—slightly oxidized by the washing media employed. (5a)

Preparation of Graded Abrasives for Metallographic Polishing. J. L. Rodda. *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 438, Sept. 1931, 9 pages.

Sized abrasives more suitable than those on the market can be conveniently prepared. Detailed directions are given for the preparation of alumina particles of various sizes. For polishing Zn and its alloys, the following 4 grades of alumina were found to be satisfactory:

Time required to settle 1 in.	Ratio of diameter of largest particle
4 hr.	1
30 min.	2.82
3 min.	8.96
20 sec.	26.8

The coarsest grade is used after grinding with 000 emery paper. Polishing with the 20 sec. grade is usually omitted if the sample is to be etched. Other grades would probably be better suited for metals of other hardness. Commercial alumina is dispersed in a colloid mill, the suspension allowed to settle for a definite time, and the top layer siphoned off. A thorough dispersion is produced by using a small amount of sodium silicate. After separation of the desired emulsions, it is recommended that they be prevented from settling. Micrographs of the abrasives and samples prepared by emulsions separated as described are shown. Contains 4 references. JLG(5a)

On the Coarse Grain Recrystallized Cold Drawn Seamless Steel Tubes. With an Appendix: Annealing Tests on Critically Cold Rolled Low Carbon Steel Bars. (Ueber grobkörnige Rekristallisation Kaltgezogener nahtloser Rohre aus Flussstahl. Mit einem Anhang: Glühversuche mit kritisch kaltgewalzten Stäben aus Kohlenstoffarmem Flussstahl.) A. Pomp & E. Holweg. *Kaiser Wilhelm Institut für Eisenforschund*, Vol. 13, No. 1, 1931, *Report* 171, pages 1–28; *Stahl und Eisen*, Vol. 51, May 7, 1931, pages 595–597.

It is known that the physical properties of cold drawn or cold rolled and annealed low carbon steel (up to 20% C) are impaired when the cold work amounts to from 8% to 16% and the annealing is performed between 600–800° C. Since it was also known that a coarse grain sometimes occurs in recrystallizing cold drawn seamless steel tubes, a study was made to learn if the above laws also hold in manufacturing tubes. The tests on notch toughness and grain size show the following results. The reduction of the cross-section of the tubes always amounted to 10% but the reduction of the wall thickness was 10%, 5% and 0%. The annealing temperatures were between 600° and 920° C. and the annealing times were 10, 30, 60 and 360 mins. The notch toughness decreases in the critical annealing temperature range. A minimum occurs at temperatures between 750° and 800° C. Though it should be expected that a maximum grain size corresponds to the minimum of notch toughness, this is not materialized. With the exception of the 360 mins. annealing, all grain size diagrams show 2 maxima, the one at 700° C. and the other at 800° C. Only the latter one corresponds to a minimum of notch toughness. Therefore, a coarse grain cannot be the only cause of a low notch toughness. Microscopic examinations revealed that the type of pearlite and cementite has an essential bearing upon the notch toughness and it is shown that the notch toughness varies even if the grain size of the samples tested is the same. Low notch toughness can be due to the formation of intersticial cementite. Additional experiments were carried on to elucidate the conditions of the formation of intersticial cementite. GN(5a)

The Constitution of Alloys of Silver and Mercury. A. J. Murphy (National Physical Laboratory). With an Appendix on the X-xay Examination of the System Silver–Mercury by G. D. Preston. *Institute of Metals, Advance Copy* No. 577, Sept. 1931, 21 pages; *Engineer*, Vol. 152, Oct. 2, 1931, page 358.

Alloys throughout the entire series were studied. The Ag-rich alloys were heated above their melting points in sealed quartz tubes in a steel bomb. The pressures developed were as great as 250 atmospheres. Cooling curves were obtained while the alloys cooled in the bomb. Some of the Hg-rich alloys were examined microscopically at sub-atmospheric temperatures. Progressive additions of Hg to Ag produced a continuous lowering of the liquidus down to the melting point of Hg. No alloy has a freezing point below that of Hg. Hg dissolves in Ag to form a solid solution containing up to 55% Hg at 276° C. The solubility of Hg probably decreases at lower temperatures. Two intermediate phases are formed, β, containing 40% Ag, dissociates at 276° C. into a Ag rich solid solution and liquid while γ contains 29–30% Ag and dissociates into β plus liquid at 127° C. An X-ray examination showed that β had a hexagonal close-packed lattice with, a = 2.98 A. U., and c/a = 1.62. γ has a body-centered cubic lattice with a parameter of 10.0 A. U. The effect of pressure on the results obtained is considered, and it is concluded that conditions were not greatly affected by the necessarily high pressures in the Ag-rich alloys. 14 references. Structure & X-Ray Analysis (5b)

The Determination of Crystallite Orientation. G. Tammann. *Metal Industry*, London, Vol. 37, Oct. 17, 1930, page 372.

Abstract of paper read at the autumn meeting of the Institute of Metals at Southampton. Describes principal methods for determining the orientation of the crystallites in metals and results of their application to various metals are given. See also *Metals & Alloys*, Vol. 1, Dec. 1930, page 908. VSP(5b)

The Diffraction of Electrons by Single Crystals. G. P. Thomson. *Proceedings Royal Society*, Vol. 133, Sept. 1931, pages 1–25.

Experiments on the diffraction of electrons of 30–50 kilovolts by single crystals of Cu and Ag are described. They show a widely extended pattern of diffraction spots. The usual wave theory can be extended to account for these patterns by supposing that the etched surface is composed of a number of lumps of dimensions of the order of 10^{-6} cm. These may in some cases be the portions left between adjacent etching pits. The nature of the surface prevents any effect of inner potential being detected. A detailed agreement exists between theory and experiment, even in the case of the more irregular "exceptional" patterns, the only discrepancy being probably due to a 2% distortion of the surface lattice in one specimen. No sign was found of reflection by "forbidden" crystal planes or of half-order spectra. Some experiments on Cu electrolytically deposited on single crystals of the same showed: (a) a strong tendency for the deposit to follow the underlying Cu in orientation; (b) a marked difference of spacing (4:45 instead of 3:61) in some cases and the appearance of spots not characteristic of the ordinary face-centered structure of Cu. Diffraction spectra are produced from a cleavage of rocksalt, and also well marked Kikuchi lines. The spectra of different orders are not evenly spaced. This seems to indicate an inner potential of about +10 volts for rocksalt. The depth of penetration of the rays under the conditions of oblique incidence used is about 10^{-7} cm. For both Cu and Ag, the position of the spots and Kikuchi lines is in excellent agreement with the simple theory. In particular, there are no "forbidden" reflections or half-order spectra. In some cases, the Kikuchi lines are represented by blackened strips. The cause of this is not explained. Explanations are suggested for some of the anomalies observed by other workers. WAT(5b)

Measurements of Elasticity with X-Rays. (Elastizitätsmessungen mit Röntgenstrahlen.) G. Sachs & J. Weerts. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft XVIII, 1931, pages 39–45.

See *Metals & Alloys*, Vol. 2, Mar. 1931, page 65. (5b)

X-Ray Determination of the Solubility of Magnesium in Aluminum. (Röntgenographische Bestimmung der Löslichkeit von Magnesium in Aluminium.) E. Schmid & G. Siebel. *Zeitschrift für Metallkunde*, Vol. 23, July 1931, pages 202–204.

The precision X-ray camera devised by Sachs and Weerts (*Zeitschrift für Physik*, Vol. 60, 1930, page 481) was used to determine the solid solubility of Mg in Al. The variation in the side of the unit face-centered unit cube of Al, a_0, with increasing Mg was determined in quenched (from 445° C.) alloys. a_0 varied almost linearly with atomic percent of Mg from 4.41 A. U. in pure Al (Al = 99.83%, Fe = 0.10%, Si = 0.07%) to 4.122 in an alloy with 17.40 atomic percent Mg. The solid solubility of Mg in Al at 445° C. is 16.8 atomic percent Mg, and the increase of a_0 is 0.0047 A. U./atomic percent dissolved Mg. The quenched alloys were reheated to a series of temperatures in order to establish equilibrium. a_0 was determined on these quenched alloys and the solid solubility pertaining to this temperature were read from the curve expressing a_0 as a function of Mg-content. The solid solubility curve determined in this way agreed closely with that determined microscopically by Dix and Keller (*Chemical Abstracts*, Vol. 23, page 2685), but indicated a slightly greater solid solubility at high temperatures and a slightly smaller solubility at low temperatures. The Application of X-Rays in Foundries. (Röntgentechniek in het Gieterijbedrijf.) G. B. van Straaten. *De Gieterij*, Vol. 4, Sept. 1930, pages 144–149.

The Metalix-X-ray apparatus made by Philips' Lamp Works (Eindhoven, Holland) is briefly described with its applications in foundry practice. HSvK(5b)

The Knowledge of Atomic States in the Metal Lattice on the Basis of Magnetic Measurements. (Zur Kenntnis der Atomzustände im Metallgitter auf Grund magnetischer Messungen.) E. Vogt. *Zeitschrift für Elektrochemie*, Vol. 37, Aug.–Sept. 1931, pages 460–466.

The author tries to find explanations for the structure of metals and the nature of the metallic state from the magnetism of the metals. His method is particularly to determine the quanta state of the metal atoms in the lattice structure because the quantum theory rests on the exact measurements available from spectroscopic observations. The dependence on temperature which is expressed by the law of Curie shows a certain inexplicable exception in a paramagnetism which is constant at varying temperatures. For this reason, Pauli developed a theory on the basis of Fermi's statistics which yielded, by ascribing to the atom in the metal lattice the same twist or spin as in the free atom, the possibility of calculating this state of magnetism which has so far been without explanation. A great number of tests with alkali and alkali earth metals are described; the curves of these show the soundness of the theory. On this basis, the author tries to elucidate the formation of solid solutions in metallic alloys. The diamagnetic metals, Au-Ag and Au-Cu, are particularly investigated. Their magnetic behavior shows clearly that the atoms in the solution must be in a different quantum state than those in the pure metal; this indicates a definite diamagnetic configuration of the electrons. 33 references. Ha(5b)

Recrystallization of Sheet Aluminum. (Zur Rekristallisation von Aluminiumblech.) E. Schmid & G. Wassermann. *Metallwirtschaft*, Vol. 20, May 22, 1931, pages 409–410.

Contains 4 references. Contrary to previous beliefs the authors show that pure aluminum has a definite cubical structure after recrystallization. X-ray pictures were taken at 3 different angles of 99.74% pure Al which had been annealed for 5 hours at 500° C. The faces of the cubes lie in the plane of rolling and the edges in the direction of rolling. Tensile tests of samples cut at different angles to the direction of rolling show the influence of rolling direction. CEM(5b)

The Casting Texture of Metals & Alloys. (Ueber die Gusstextur von Metallen und Legierungen.) F. C. Nix & E. Schmid. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 10, 1930, pages 79–89.

The casting texture of a series of metals is examined by X-rays. See *Metals & Alloys*, Vol. 1, Mar. 1930, page 427. Ha(5b)

On the Structure, Formation and Decomposition of Martensite. (Om martensitens struktur, bildning och sönderfall.) Einar Oehman. *Jernkontorets Annaler*, Vol. 115, July 1931, pages 325–357.

X-ray investigations with high dispersion focusing cameras have shown that the tetragonal martensite lattice dimensions vary continuously with the C content. This result indicates that the tetragonal martensite is a supersaturated solution of C in α-Fe, and that the C content is the same as that of the austenite from which it forms. The hypothesis is advanced that the structure consists of C_2 groups oriented parallel to the tetragonal axis. This explains the observed density, volume increase with C content and the elongation of one of the crystal axes. Decomposition on tempering takes place continuously with a progressive decrease in the axial ratio. HCD(5b)

Studies on Magnesium and Magnesium Alloys I. (Studien an Magnesium und Magnesium legierungen I.) E. Schiebold & G. Siebel. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 17, 1931, pages 61–70, 27 figures.

X-ray crystallographic examination of Mg single crystals, of the same after deformation, of extruded Mg alloy (6.3% Al 1% Zn), of wire of another alloy (3% Al, 1% Zn) and of rolled pure and alloyed Mg sheet. The slip planes and direction of slip were found to be similar to those in Zn and Cd, i. e., the basal plane (0001) and the diagonal axis $[11\bar{2}0]$. Twinning, as previously pointed out by Mathewson and Phillips, is along the $(10\bar{1}2)$ plane and in some cases also along the $(10\bar{1}1)$ plane. Cold extruded rod and wire show sometimes a fiber structure or a transition, especially on working at higher temperatures, to a ring-fiber structure. On forcing through a cylindrical die, the ring-fiber structure changed to a regular fiber structure. In Mg sheet, the basal plane lay in the rolling plane within the wide variation of 100° C. After recrystallization, the rolling texture shown by pole-figures, was preserved, not being altered by annealing at 550° C. WAT+HWG(5b)

The Spark Spectra of Tellurium—Te IV and TeVI. K. R. Rao. *Proceedings Royal Society*, Vol. 133, Sept. 1931, pages 220–227.

The spark spectra of Te has been examined by means of a vacuum grating spectrograph in the region λ1500 to λ500 with and without inductance; photographs have also been taken with quartz instruments of discharges through Te vapor in capillary tubes. With the aid of these data, the doublet system of Te IV has been identified and a term scheme has been suggested, by applying a Rydberg formula (with 16R constant) to 2 members of each of the sharp and diffuse secondary series. The largest term, $5pP_{1/2}$ = 305,091 cm.$^{-1}$, gives an ionization potential of about 37.7 volts for Te IV. Three pairs with $\Delta\gamma$ = 11,814 cm.$^{-1}$ have also been identified as being the combinations between the deep 5sS, 5pP, 5dD and 6sS terms of Te VI. An approximate term scheme is proposed. The ionization potential is found to be about 72.0 volts. WAT(5b)

Atomic Physics and Metallurgy. (Atomphysik und Metallkunde.) E. Piwowarsky. *Metallwirtschaft*, Vol. 10, Sept. 4, 1931, pages 689–695.

Contains 23 references. A review of recent studies and theories on the use of X-rays in the study of the constitution of metals, the space lattices of the elements, the lattices of solid solutions and chemical compounds, the structure of atoms and explanation of the periodic system of elements, and electron lattices and properties of elements. While the theoretical study along these lines has been helpful to metallurgy and systematic alloying, a number of gaps in the knowledge and prediction of the properties of new alloys still exist. CEM(5b)

X-Rays for Metal Examination. The Significance of Laue-Spectra of Metals. V. E. Pullin. *Journal Institute of Metals*, Vol. 47, Feb. 1931, pages 3–9.

The principle of X-ray examination by a sharply defined beam of monochromatic radiation falling on and penetrating a metallic specimen is explained. Changes which take place in the crystal arrangement show in photographs taken with this beam and, thus, demonstrate clearly any change in the arrangement which is worked by any treatment. A series of micrographs illustrate this for rolling and heating. Ha(5b)

X-Ray Analysis Applied to Detection of Defects in Foundry Practice. (Röntgenologische Erkennungsmöglichkeiten von Gusserzeugungsfehlern in Giessereibetrieben.) H. Reininger. *Giesserei*, Vol. 17, Jan. 17, 1930, pages 63–71.

The advantage of X-ray analysis in foundry practice is set forth. An attempt should be made to apply X-ray examination not only to castings but also to certain cores and molds. (5b)

Non-Destructive Testing by Gamma Rays from Radium. Robert F. Mehl. *Journal American Society Naval Engineers*, Vol. 43, Aug. 1931, pages 371–395.

The article describes the apparatus used by the Naval Research Laboratory and discusses experiments carried out on steel castings. A large number of photographs and radiographs are presented showing the results obtained. It is inevitable that this new method of radiographic inspection should be compared with the X-ray method. This new method offers advantages in greater simplicity of operation, almost complete portability, far greater penetration, and more satisfactory performance on irregular sections. It suffers from the rather longer exposure times and from the lack of general availability of radium. The cost of an inspection method is naturally of very great interest to industry and before it can be claimed this new method will have a wide application, it will be necessary to show that its costs are not prohibitive. Such surveys as have been outlined in this paper, however, indicate that a sensible prosecution of the method industrially should result in costs which are well within the admitted range of inspection costs. It is of interest to note that the Navy has considered the matter carefully and has decided to provide the Navy Yards on the east coast with radium for this purpose. This radium will be held at the Naval Research Laboratory. The total amount will be one-half gram divided into 3 portions so that separate portions can be sent to the various Yards as required. WAT(5b)

The Reflection of Long X-Rays. C. B. O. Mohr. *Proceedings Royal Society*, Vol. 133, Sept. 1931, pages 292–303.

The refraction indices of long X-rays are investigated by the total reflection method, using a vacuum spectrograph, and the characteristic X-rays isolated by either a crystal or ruled grating. The critical angles were determined for quartz, calcite, steel, glass, Ag and Au at 8.32 A. U. (Al $K\alpha$), and for quartz, glass and steel at 13.3 A. U. (Cu $L\alpha$), and compared with the values given by the classical Drude-Lorentz dispersion formula. For the light mirrors, quartz, calcite and glass, agreement was found within the limits of experimental error between the observed and calculated values of the critical angle, and for the rate of fall of intensity of reflection near the critical angle. For the denser mirrors, steel, Ag and Au, however, increasing large discrepancies were found to occur with increasing density of the reflector. WAT(5b)

Scattering of High Velocity Electrons by Thin Foils. H. V. Neher. *Physical Review*, Vol. 38, Oct. 1, 1931, pages 1321–1341.

With a narrow, homogeneous beam of electrons, scattering by thin foils of Al, Ag and Au, has been investigated. Voltages up to 145 kv. (β = 0.63) were used. Comparison of values of scattering for Al, Ag and Au shows that ρ increases faster than Z^2. For Al, the dependence found experimentally agrees well with either Mott's or Rutherford's equation. The latter also gives the correct dependence on angle for Au and Ag. Mott's equation is not applicable for these heavy elements. Absolute values for scattering for Al compared with theory give ρ = 1.32 of the value given by Mott's equation. This relation is valid within the ranges θ = 95°–173°, V = 56–145 kv. Secondary electrons coming from the foil are distributed according to the simple cosine law. No evidence of loss of energy due to radiation is found up to one-half the energy of the primary beam. WAT(5b)

The Periodic System of Atomic Nuclei and the Principle of the Regularity and Continuity of Series. William D. Harkins. *Physical Review*, Vol. 38, Oct. 1931, pages 1270–1288.

New relations which concern the existence and stability of atomic nuclei are presented, together with a discussion of evidence for the relations given earlier as exhibited by the newer data on the existence of isotopes. It is shown that the 4 series, He, U, Li and Be, exhibit a considerable amount of regularity and are now almost continuous. WAT(5b)

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Magnetic Methods of Testing Butt Welds. T. R. WATTS (Westinghouse Elec. & Mfg. Co.). *Preprint, American Society for Testing Materials,* Mar. 1931, 14 pages.

Shop-testing of butt welds may be done by magnetizing the welded specimen and sifting on iron powder. Serious faults are shown by an accumulation of the powder over the bad spot. For permanent record, Van Dyke paper is laid over the weld, iron powder sprinkled on and an arc light used to print the pattern of the powder. Defects may be obscured through the roughness of the weld. A portable weld-test meter, which is a simple permeameter, is used to span the weld. Comparison of readings across the weld with those on the material welded indicate the quality of the weld. Such tests on a series of welds ranging from completely welded down to those with only 10% of fusion, are plotted to show good correlation with the results of tensile tests. Another type of test meter contains a stationary bar of steel of high permeability (hypernik) and a movable bar of the same connected to a pointer. When a welded piece is magnetized, and this tester placed over the weld, the flux density is affected by imperfections in the weld and the pointer is correspondingly deflected. If the readings on the parent metal each side of a weld average 0.82 and the weld reads 1.5, and the calibration chart shows that for 0.82 parent metal a perfect weld should read 1.2, then the weld has a magnetic efficiency of 1.2/1.5 = 80%. These magnetic methods plus visual inspection are claimed to detect most faults of any consequence in a butt weld. See also *Metals & Alloys,* Vol. 2, Feb. 1931, page 36. HWG(6)

Determining Results of Abuse in Advance. R. G. ROSHONG & U. A. WHITAKER. *Machine Design,* Vol. 3, Aug. 1931, pages 31–34.

Description of accelerated tests to determine the wear in Hoover vacuum cleaners. Ha(6)

The Resistance to Wear of Carbon Steels. SAMUEL J. ROSENBERG (U. S. Bureau of Standards). *American Society for Steel Treating, Preprint* No. 7, 1931, 18 pages.

Paper read and discussed at the Boston Convention of the Society in Sept. 1931. Illustrated by 31 photomicrographs and numerous curves; 5 references to the literature are cited. The author presents the results of tests of C steels in the Amsler wear testing machine under combined rolling and sliding friction and heavy pressures. Annealed C steels gave relatively poor resistance. Normalized steels showed low resistance greatly improved with increase in the C content. The hardened steels showed low wear resistance in the lowest C ranges but as the C increased, the wear resistance increased rapidly to about 0.6% C and then very slowly with further increase in the C content. Tempering lowered the resistance. Martensitic-troostitic structure gave the best resistance. Lamellar pearlite in normalized steels gave nearly as good results as hardened condition. Spheroidal cementite gives poor resistance. This type of wear results in marked distortion of the material adjacent to the wearing surface. WLC(6)

The Right Amount of Metal in the Right Place. F. W. SLANTZ. *Product Engineering,* Vol. 2, Sept. 1931, pages 385–389.

Structures of such shape that the stresses cannot be analyzed mathematically require laboratory determinations Even then, the best design with regard to stresses will result in a defective product if its proportions cause difficulty in producing an article with sound metal throughout, free from residual stresses. Impact resistance increases with yielding and uniformity of stress distribution; but excess metal causes increased stiffness and wide stress variations. Hence, the necessity for accurate stress determination for structures subject to dynamic loads. Methods for making tests and arranging the instruments at the proper places are described and a few examples of properly laid out designs illustrated. Ha(6)

Hardness of Chromium as Determined by Vickers-Brinell, Bierbaum and Mohs Methods. RICHARD SCHNEIDEWIND. *American Society for Steel Treating, Preprint* No. 2, 1931.

Paper presented before the Boston Convention of the Society, Sept. 1931. 18 references to the literature are made. Hardness results on Cr plate, Cr plate subjected to various treatments, and annealed cast Cr are given. Curves showing the relation between various methods of hardness determination are given. WLC(6)

Stretching of Gold-Silver Single Crystals. (Zugversuche an Gold-Silberkristallen.) G. SACHS & J. WEERTS. *Mitteilungen der deutschen Materialprüfungsanstalten,* Sonderheft 13, 1930, pages 120–128; *Zeitschrift für Physik,* Vol. 62, 1930, pages 473–493.

The critical gliding force (single crystal yield point) is at a maximum at 50 atomic % (35.5% Ag by weight). Some comments are given on the pure metals Au, Ag and Cu. Cu single crystals harden up on deformation twice as much as Au or Ag. The addition of one of these elements to the other in solid solution produces, in single crystals, a raising of the elastic limit, which also becomes more clearly defined, a raising of the hardening up to a greater amount of slip, and an increased dissymmetry of the process of slip. HWG(6)

Nick-Break Testing Methods. (Kritische Untersuchung des Schlag-Kerb-Faltversuchs nach Kr K 100, hinsichtlich seiner Eignung zur Prüfung der Kerbzähigkeit von blankgezogenen Werkstoffen.) F. SAEFTEL & H. RUDOLPH. *Mitteilungen aus den Forschungsanstalten des Gutehoffnungshütte Konzerns,* Vol. 1, Feb. 1931, pages 61–66; *Automobiltechnische Zeitschrift,* Vol. 33, 1930, page 492.

According to a German specification, a cold drawn steel specimen is sawed half way through with a 2 to 2½ mm. saw cut, gripped in a vise level with the cut, and hit with a hammer. The specimen must bend at least 30° before fracture and the fracture must be matt-gray. The effect of a sharp and a dull saw, of a cut 2 mm. wide and one 2½ mm. wide, and of the point at which the specimen is hit with the hammer was examined. It is shown that these variables so greatly affect the test that it is useless and should be displaced by a properly carried out notched bar impact test on a pendulum machine. HWG(6)

Fabrication of Rails. (La Fabrication des rails de chemins de fer.) L. PERSOZ. *Aciers Spéciaux, Métaux et Alliages,* Vol. 6, Apr. 1931, pages 166–178.

Complete discussion of making rails based on studies made by O. Pilz, H. Meyer & W. Schaeffer (see "Comparative Investigations of Rails with Water-Hardened Surface," *Metals & Alloys,* Vol. 2, Apr. 1931, page 80). Si steel is much preferred for use in Austria in making rails. GTM(6)

The Penetration of Electro-Magnetic Waves into Highly Saturated Iron. (Das Eindringen elektromagnetischer Wellen in hochgesättigtes Eisen.) F. OLLENDORFF (Technische Hochschule Berlin). *Zeitschrift für technische Physik,* Vol. 12, Jan. 1931, pages 39–50.

This theoretical paper pertains to the penetration of electromagnetic waves into highly saturated Fe and particularly considers the variations in permeability. The losses due to hysteresis are disregarded in ingot iron and taken into account in approximation in cast iron. EF(6)

The Flow and Fracture of Aluminum under Prolonged Loading. D. HANSON & M. A. WHEELER. *Rolling Mill Journal,* Vol. 5, Mar. 1931, page 208.

Abstract of a paper presented before the British Institute of Metals, Mar. 11, 1931, at London. See *Metals & Alloys,* Vol. 2, Aug. 1931, page 144. JN(6)

Fatigue of Metals & Alloys (6f)

The abstracts appearing under this heading are prepared in coöperation with the A. S. T. M. Research Committee on Fatigue of Metals.

Damping Ability of Ferrous and Non-Ferrous Metals in Repeated-Torsional and Repeated-Bending Tests. (Die Dämpfungsfähigkeit von Eisen- u. Nichteisenmetallen bei Dreh- und Biegeschwingungs-Beanspruchung.) J. Schmidt. *Mitteilungen des Wöhler-Instituts*, No. 9, 1931, 52 pages. 39 figures, 8 references.

Damping of a number of alloys was compared, using both the Föppl-Buseman torsion machine and the Föppl-Heydekampf-Wazau repeated bending apparatus. On the latter, the damping was evaluated by determining the use of temperature of the specimen. The ratio of the damping ability in torsion to that in bending ran from 0.52 to 0.60 except for Electron metal, in which it fell to 0.35. This is ascribed to a change in damping properties taking place as the test progresses. The ratio of torsion endurance limit to endurance limit in repeated bending was also determined and found to run from 0.45 to 0.77. On steels of 50,000–130,000 lbs./in.^{2} tensile strength, it varied from 0.52 to 0.68. Endurance tests were run for 2 million cycles, then the stress raised and another 2 million cycle run made, and so on till fracture occurred. Although leaded bronze, phosphor nickel bronze, Al and electron were studied, no runs were continued over 2 million cycles. This small number of cycles in endurance tests of such materials, and the probability of strengthening by understressing during the test, make the endurance figures of little value, according to the abstractor's point of view, for accurate determination of this ratio. The author concludes that the ratio of damping ability and of endurance limit under torsion and bending are characteristic constants of the different materials. HWG(6f)

Detection of Cracks and the Starting of Fatigue Fractures. (Das Feststellen von Rissbildung und des Beginnens von Dauerbrüchen.) Fr. Hirschfeld. *Automobiltechnische Zeitschrift*, Vol. 34, Oct. 10, 1931, pages 639–640.

The importance of the detection of hair cracks and the finest fissures in parts which are subject to fatigue stress, such as the front axles of automobiles, is noted. These fine cracks are bound to lead to fracture in time. One method places the part to be tested in warm oil for some time, cleans it thoroughly with benzine and paints it with lime. If cracks are there, oil spots will show in the white color at these spots. Another test, which does not require so much time, consists in placing the part between 2 electromagnets and strewing iron fillings on it; these arrange themselves in a known manner in the magnetic field. After the current has been cut off, the filings are wiped away with petroleum; but the filings stick at the cracks, so that a thorough examination can be made here. Ha(6f)

Maximum Stress, Its Influence on Cost and Service Life of a Structure. E. Chapman. *Industry & Welding*, Vol. 2, Oct. 1931, pages 25–32.

The Effects of Rapidly Acting Stress. J. J. Guest. *Proceedings Institution Mechanical Engineers*, No. 5, 1930, pages 1273–1304.

With discussion. Experiments were made to determine the cause of failures under modern stress actions, especially if connected with a large number of repetitions of the action. The method of the author's tests and the apparatus used are fully described. He concludes that the stress which is the important one in design (that at which steel begins to receive permanent effects) is very little affected by the suddenness or the brief duration of the loading and that any higher stresses reached in an impact are due to the internal viscous action and are accompanied by permanent effects dependent upon the stress duration. Ha(6f)

Effect of Surface Decarburization on Fatigue Properties of Steel. C. R. Austin (Westinghouse Elec. & Mfg. Co.). *Metals & Alloys*, Vol. 2, Sept. 1931, pages 117–119.

Six references are cited. A 0.38% C steel with 1.50% Mn was used for these tests. 2 sets of 6 specimens, one only slightly over size and other machined to size were treated under identical conditions in wet H to decarburize the surface and then normalized in H to prevent injury to the surface. The over size specimens were turned to size removing the decarburization and the others finished as to surface without removing an appreciable amount of material. A microscopic examination showed the desired decarburization (0.010 inch) had been obtained. Rockwell and tensile tests show the material to be uniform. The fatigue limit was shown to be decreased from 47,000 lb./in.^{2} to 38,000 lb./in.^{2} due to the presence of 0.010 in. depth of decarburization on the surface of this steel in the normalized condition. A review. VVK(6f)

Electro-dynamic Oscillating Devices for Testing Transmission. (Elektrodynamische Schwingungseinrichtungen zur Prüfung von Leitungsseilen.) A. v. Engel. *Siemens-Zeitschrift*, Vol. 11, Nov. 1931, pages 489–494.

The electro-dynamic method offers the advantage of being able to test the oscillating body under any condition of oscillation. The current can be transmitted to it by flexible leads connected at the nodes. In this way, transmission wires, ropes, hollow cables have been investigated for the number of oscillations at definite amplitude of the oscillation, frequency of current and pre-tension until fracture occurred. The energies necessary to excite oscillation are discussed theoretically and equipment for the production of a wide variation of the frequency for the excitation of the electromagnets used for the maintenance of the oscillations is described. Ha(6f)

On the Torsional Oscillations of Iron Wire. A. G. Hill. *London, Edinburgh and Dublin Philosophical Magazine and Journal of Science*, Series 7, Vol. 12, Aug. 1931, pages 566–572.

The influence of the diameter of the wire on the amplitude of torsional oscillations was investigated. In the equation $y^n(x-a)=b$ representing the extent of the oscillation y, the constants a, b and n were determined and represented in curves. Ha(6f)

A Seven-ton 50 Cycle Fatigue Testing Machine. B. P. Haigh & T. S. Robertson. *Proceedings American Society for Testing Materials*, Vol. 31, Part 2, 1931, pages 221–235.

Description of a larger model of the Haigh endurance testing machine than that previously available. HWG(6f)

ELECTRO-CHEMISTRY (7)

Electroplating (7a)

Researches on Silver Plating. E. B. Sanigar. *Monthly Review, American Electroplaters' Society*, Vol. 18, Mar. 1931, pages 26–30.

While the silver bath is easy to work and easy to control, the chemical equilibria in the solution must be quite complex, and no complete theory explaining the deposition of silver from the double cyanide solution has yet been put forward. Nevertheless the author presented brief theories and reported practical results in agreement therewith, obtained recently in England, from which country he had just come. MFB(7a)

Developments in Low pH Nickel Plating. W. M. Phillips. *Metal Industry*, N. Y., Vol. 29, Oct. 1931, pages 433–435.

Paper from the *Monthly Review of the American Electroplaters' Society*, Sept. 1931. Includes discussion. Hard Ni deposits are obtained by plating at low pH values at temperatures around 100° F. A graph is given showing variation of quality of plate with changes in temperature, current density and pH. See also *Metals & Alloys*, Vol. 1, Dec. 1930, page 911. PRK(7a)

Metallography for the Welder. (Metallographie für den Schweisser.) Karl Tewes. *Oberflächentechnik*, Vol. 7, Nov. 18, 1930, pages 211–212; Dec. 2, 1930, pages 221–223.

A short treatise on the problems and methods of metallography and the preparation of samples for examination; the diagrams and photomicrographs are explained. Ha(7a)

Explanation of the Mechanism of Electrolysis and Electroplating. M. de Kay Thompson. *Metal Cleaning & Finishing*, Vol. 2, Oct. 1930, pages 833–836; Nov. 1930, pages 949–952, 968.

Non-mathematical discussion of the mechanism of electrolysis, conducting power of solutions, factors determining which of several ions will be deposited, electrochemical equivalent, different forms of metal deposits, and protection afforded by plating. See "A Model to Explain the Mechanism of Electrolysis," *Metals & Alloys*, Vol. 1, Sept. 1930, page 741. MS(7a)

On the Effect of Mercury in Zinc Cyanide Plating Solutions. M. deK. Thompson & W. E. Charles. *Preprint, Transactions Electrochemical Society*, Vol. 60, Sept. 1931, pages 89–93.

Hg in cyanide zinc plating baths makes the deposit possible at voltages appreciably lower than when Hg is absent. Measurement of electrode potentials in the cyanide solution show Zn with 2% Hg has a less negative potential than straight Zn. H overvoltage on cast iron is lower than on steel, but there is no definite relationship between H overvoltage and C content of the steel. At a current density higher than 2 amp./dm.^{2}, both Zn and Hg-Zn polarize the deposition of H. LCP(7a)

Electrodeposition of Iron, Copper and Nickel Alloys from Cyanide Solutions. Part I. L. E. Stout & C. L. Faust. *Preprint, Transactions Electrochemical Society*, Vol. 60, Sept. 1931, pages 173–198.

Ternary alloys of Cu, Ni and Fe are produced by electrodeposition from complex cyanide solutions. These alloy deposits are bright and vary in color from copper-bronze to platinum-white, as the composition changes from Cu-rich to Ni-rich or Fe-rich varieties. Cu content of the deposit may vary from 45 to 94%, Ni content from 5 to 42% and Fe content from 0 to 26%, while the Cu content of the bath varies from 0.0025 to 0.05 *N*., Ni content from 0.15 to 0.165 *N*., and Fe content from 0.325 to 0.475 *N*. The total metal content of the bath was 0.5 *N*. in all cases. The current efficiency ranges approximately from 0.1 to 35% at current densities of 1.5 to 10 amp./dm.^{2}, 2 to 10 volts, and 25 to 70° C. Platinum cathodes and duriron anodes were used. The bath was made of $K_4Fe(CN)_6$, $KCu(CN)_2$, $K_2Ni(CN)_4$, potassium tartrate, equivalent to 14 g./l. tartaric acid, and free potassium cyanide, 0.5 g./l., but no free caustic alkali. The Cu in deposit is always higher than that in the bath, Fe in deposit is always lower than that in the bath. Higher current densities tend to suppress copper deposition and promote nickel and iron deposition. Temperature has little effect except upon cathode efficiency which is somewhat favored by high temperatures. In order to deposit any Fe at all with Cu and Ni, the bath must contain tartrate and practically no free cyanide. LCP(7a)

Plating of Iron and Steel Castings with Cadmium. (Das Plattieren von Eisen- und Stahlguss mit Kadmium.) E. T. Richards. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, June 26, 1931, pages 516–518.

The plating with Cd offers great advantages over plating with Zn. Among the advantages claimed are: Solubility potential of Cd is higher than that of Fe but lower than that of Zn, so that an equal amount of plated Cd offers a considerably better protection against corrosion than Zn. The chemical reaction of Cd is lower and it, therefore, is more resistant to the action of alkalies and acids. Cd coatings are thinner and give sharper contours and are, for this reason, better suited for precision work. The degree of adhesion of Cd on Fe is much greater than that of Zn and, therefore, the tendency to spall and scale is less. The color of plated Cd, similar to Ag, is more pleasing than that of Zn. The preparation of pieces is described and 3 of the most widely used bath compositions are given. The costs are not prohibitive although they are, at present, higher than for Zn. Ha(7a)

The Finishing of Metal Wares by Electroplating with Silver and Gold. (Die Veredelung der Metallwaren durch die galvanische Versilberung und Vergoldung.) K. Schuch. *Oberflächentechnik*, Vol. 8, Sept. 16, 1931, pages 195–199.

The method usually used at present for both silver and gold is the cyanide bath. Recipes for the composition of the electrolytes and the preparation of the salts are given. Defects are discussed and remedies described. Sometimes the contact method of depositing metal is applied by dipping the objects in a solution or boiling them in it. The respective salt solutions are also given. Methods for recovering gold and silver residues are described. Ha(7a)

Spotting Out. August G. Hoffman. *Metal Industry*, N. Y., Vol. 29, Sept. 1931, page 382.

To prevent spotting out on bronze plated iron castings, they were doubly rinsed in hot and cold water, then dried at 180° F., and dropped into cold water; this process is repeated 3–5 times. PRK(7a)

Modern Processes of Nickel Plating and Chrome Plating. (Les procedes modernes de nickelage et de chromages.) *L'Industrie Electrique*, Vol. 40, Oct. 25, 1931, pages 469–475.

The general principles of the electro-deposition of Ni and Cr are explained and the methods of high-speed plating are discussed. The difficulties encountered, especially the maintenance of the acidity of the baths, the avoiding of the Ni electrode becoming passive and the influence of the temperature of the bath are treated in detail. Ha(7a)

Electro-Depositions on Aluminum. (Elektrolytische Niederschläge auf Aluminium.) M. Ballay. *Deutsche Motorzeitschrift*, Vol. 8, August 1931, page 294.

Difficulties involved in the electroplating of Al and recent performances (Cu, Ag, Cd, Au, etc.) of overcoming those difficulties by utilizing an intermediate layer of Ni. Solution used: iron chloride containing a small quantity of HCl. Most suitable temperature: 90–100° C. Prevention of hydrolysis is by a further addition of tartaric acid. The analyses of the alloys employed are given. Bending tests were performed to study the electroplated samples. Composition of solution most recommended: 6–22 g. Fe/0.1–0.7 Mol HCl/liter. See also *Metals & Alloys*, Vol. 2, Nov. 1931, page 259. EF(7a)

METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

Galvanizing. W. H. Spowers. *Wire & Wire Products*, Vol. 6, Sept. 1931, pages 360–361, 372–373.

Relates to the progress made in using the wash-zinc-chloride technique instead of the hydrochloric flux; the dross reduction obtained by the former method is appreciable. Another progressive step concerns the open hearth where the tight bonding method is recommended for producing a fully Si-killed steel without any Al. Ha(8)

Advancements in Galvanizing Machine Drives. R. J. Wean (Wean Engineering Co.). *Rolling Mill Journal*, Vol. 5, Feb. 1931, pages 135–136, 139.

Recent improvements in galvanizing machine drive design have entirely eliminated chatter in the final coating rolls and increased the efficiency of speed adjustment. The author describes and illustrates 3 types of drives for accurately adjusting the speed of finishing rolls. JN(8)

Higher the Dross, Heavier the Coating. W. G. Imhoff. *Heat Treating & Forging*, Vol. 16, Oct. 1930, pages 1289–1291.

The author discusses the relationship that exists between the dross production and the weight of the coating in galvanizing practice. The difference of the Fe content in zinc, especially of new and old, often furnishes a cause for higher losses. Ha(8)

Determination of Thickness and Quality of the Zinc Coating on Galvanized Iron. (Détermination de l'épaisseur et de la qualité des dépots protecteurs sur le fer galvanisé.) R. Vondracek. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 547–553. 3 figures, 15 references.

Gasometric determination of rate of solution of the Zn in H_2SO_4 is recommended. Typical rate curves for hot dipped, electroplated and sherardized coatings are shown. See also *Metals & Alloys*, Vol. 2, Oct. 1931, page 217. HWG(8)

Formation of Hard Zinc by Iron Salts. (Hartzinkbildung und Eisensalze.) K. Taussig. *Stahl und Eisen*, Vol. 51, July 9, 1931, pages 885–886.

Experiments show that iron salts which adhere to steels to be pickled, disintegrate when they come in contact with Zn and the iron thus formed combines with the Zn to form hard Zn. In Zn coating, therefore, careful cleaning and the addition of a sufficient amount of inhibitors is of importance. GN(8)

Factors Affecting Galvanizing Pot Life. Wallace G. Imhoff. *Heat Treating & Forging*, Vol. 17, May 1931, pages 465–467, 474.

The corrosive action of molten Zn on the steel side of the pot is fairly slow up to 860° F. but increases rapidly above 900° F. The bath temperature together with production put through the pot in unit time and the volume of the pot determine the life of a pot. These conditions are discussed in detail. A few examples of proper relationship of these factors are discussed. Ha(8)

Wire Galvanizing Process. G. K. Rylands. *Wire & Wire Products*, Vol. 6, Aug. 1931, pages 328–332, 344.

This article takes issue with the views presented previously by Whitehead in favor of the electro-galvanizing process. See *Metals & Alloys*, Vol. 2, June 1931, page 113. Ha(8)

Homogenous Lead-Coating with the Oxy-Acetylene Flame. (Das homogene Verbleien mit der Sauerstoff-Azetylen-Flamme.) R. Salelles. *Schmelzschweissung*, Vol. 10, Aug. 1931, pages 208–209; *Revue de la Soudure Autogène*, 1931, pages 2050–2053.

To obtain an intimate contact of a Pb coating on metallic containers, especially of steel, an intermediate layer of Sn and Pb is applied first; the Pb is melted on this by the flame. The steel is first cleaned by pickling with hydrochloric acid with subsequent thorough rinsing. Instructions for the proper procedure are given and a few examples are described. Ha(8)

Electro-Galvanizing. L. D. Whitehead. *Wire & Wire Products*, Vol. 6, Oct. 1931, pages 396–401.

In this article, the discussion of hot galvanizing is brought to a conclusion in which the author sums up all arguments in favor of the electro-galvanizing method. The coat of Zn so obtained is the purest obtainable. The purity extends far into the inner layers, which is a feature which other galvanizing methods do not obtain. Ha(8)

Surface Improvement of Silver Wares. (Die Oberflächenveredlung von Silberwaren.) H. Moser & E. Raub. *Korrosion und Metallschutz*, Vol. 7, June 1931, pages 134–139.

Experiments were carried out with an 83.5/16.5 Ag-Cu alloy with the object of enriching the Hg content at the surface; its commercial necessity is fully considered. A surface rich in Ag was secured by electro-deposition on one set, by a pickling method in a second set of samples and by a combined pickling and annealing process of a third group. The macroscopic changes at the surface of all specimens during the subsequent brushing with fine brass brushes and the final polishing treatment are noted. Mechanical polishing almost entirely removes the silver film, in contrast with polishing by hand. The surface finish on the electro-plated samples (10 min., 20° C., 0.3 amp/dm.^{2}) could, however, be rendered permanent and effective if the surface was given a polishing treatment previous to the galvanizing process. The surface stability was tested by submerging the specimens in a 1/100 N Na-sulphide solution for 30 secs. These pickling tests yielded the same results as the microscopic examination, i. e., the superiority of (1) hand polishing to mechanical polishing methods and (2) the coating by electro-deposition to the pickling process owing to the rather thin silver-rich surface layer of the latter. EF(8)

Developments in the Tinplate Industry. W. Charles Wright. *Iron & Steel Industry & British Foundryman*, Vol. 4, May 1931, pages 271–272, 284.

An address. CHL(8)

Hot Dipping to Inhibit Corrosion. L. K. Wright. *American Machinist*, Vol. 74, Jan. 8, 1931, pages 58–59.

Brief review of coating methods. Dipping is more satisfactory for intricate designs. Cleaning may be done by sand blasting or pickling. Gives temperature and solution for pickling. Cd melts at 970° F., Zn at 786° F. A Zn bath should run from 900° to 950° F. and parts to be plated should remain in bath for several minutes after bubbling ceases. Dipping is more costly than some methods but more effective. RHP(8)

Wire Galvanizing Processes. IV. Geoffrey K. Rylands. *Wire & Wire Products*, Vol. 6, Dec. 1931, pages 474–476, 486–488.

In this installment, issue is taken with a correspondent. It is maintained that hot galvanizing can give just as good and uniform results as electro-galvanizing. The testimony of microphotographs, that aim to show the superior bonding of the coat with the material by the electrical method, are considered. The decision is that they do not give a proper view of the matter. Ha(8)

INDUSTRIAL USES & APPLICATIONS (9)

The Use of Light Metals for Fire Engines. (Die Einführung des Leichtmetalles bei der Feuerwehr.) Schänker. *Automobiltechnische Zeitschrift*, Vol. 34, Apr. 30, 1931, pages 284–285.

According to the author, fire engines under his supervision have been reduced considerably in weight by the substitution of aluminum for auto-body steel sheets, for castings—silumin, for shapes—lautal, for structural parts of ladder—duralumin, lautal and silumin. Fireman's tools and engine appliances (tubes, couplings, deluge set, spanners, etc.) have also been made from light metal. The new engine pump weighs 2530 kg. and a 24 m. ladder, 3083 kg. less than the previous one. ER(9)

Turbo-Generator Fans. W. Sharp. *Engineering*, Vol. 131, Feb. 27, 1931, pages 292–293.

Brief article describing and giving diagrams of the various types of fans in general use. For smaller designs, fan plates and blades may be made of boiler plate having an ultimate tensile strength of 35–40 tons/in.^{2} For larger units, Ni steel is used for the blades and the plates are made from solid rolled and flattened steel sheets. For high-speed fans, Vibrac V. 30 steel is recommended. This steel has a yield point of 30 tons/in.^{2}, a high maximum stress as well as excellent elongation and reduction of area and is free from temper-brittleness. Its composition is: C, 0.3; Si, 0.15; Mn, 0.6; P, 0.03; S, 0.035; Ni, 2.5; Cr, 0.6; Mo, 0.6%. LFM(9)

Service Conditions and Quality Control of Rails for the Belgian Railways. (Les rails sur le réseau des chemins de fer Belges, leurs conditions de service et le controle de leur qualité.) J. Servais. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session Liege, June 1930, pages 389–403.

Rail service in Belgium, as in other countries, is of increasing severity. Rail steel must be sound, not fragile, and sufficiently resistant to wear. Testing for soundness and freedom from segregation is described. A 25% crop is specified, and 30% usually necessary. Impact strength has been increased by lowering the finishing temperature. On tracks in heavy service rails from the bottom of the ingot have given best results. It would be desirable to know more about the O content of rails and its relation to fragility. Raising C too high increases brittleness and favors the formation of transverse fissures. American practice is criticized and 0.50% C advised as upper limit. With this, 0.85 to 1.15% Mn is used. Raising Mn to 1$^1/_2$ or 2% does not sufficiently answer the question of wear, but is applicable in some cases. Alloying with Ni and Cr is probably too expensive for general use. Electric rails are being introduced and give marked promise. Heat-treated rails will probably be required. Fissures met in Belgian practice generally start at the surface, due to cracking from cold work, rather than at the interior. Use of long rails is advisable. HWG(9)

Production and Use of Crushed Blast Furnace Slag for Building Purposes. (Gewinnung und Verwendung der Hochofenstückenschlacke für Bauzwecke.) Schuler. *Revue Technique Luxembourgeoise*, Vol. 23, Mar.-Apr. 1931, pages 70–76.

Only acid blast furnace slags with a large percentage of silica and little Ca are used as they come from the production of Thomas iron and steel iron. The preparation, binding and additional materials, the requirements for a good slag material are explained. It should have approximately the following composition: 30–32% SiO_2, 12–16% Al_2O_3, 40–42% CaO, 4–6% MgO, 2–3% MnO, 1–1.5% FeO, 1.5% CaS, 0.12% P. The mechanical properties, with particular regard to road building, are equal to those of the best building materials, such as Syenit, Dyorit and all secondary rocks. Ha(9)

The Use of Non-Ferrous Metals in Boiler Construction. (Apparate-Maschinen- und Armaturenbau, Fabrikanlagen, Verwendung von Nichteisenmetallen im Dampffassbau.) H. Scheffel. *Apparatebau*, Vol. 41, Aug. 23, 1929, pages 193–196.

A discussion of copper, nickel and aluminum when used in boiler construction. See *Metals & Alloys*, Vol. 1, July 1930, page 631. WHB(9)

Applicability of Cupal for Contacts. (Die Verwendbarkeit von Cupal für Kontaktzwecke.) H. Schmitt & B. Wulff. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 3, July-Aug. 1931, pages 262–265.

Cupal is a rolled product with a core of Al onto which a thin layer of Cu is rolled on one side or on both sides. Tests for contact resistance have shown that this material is well suited for terminal connectors, clamps, etc. Ha(9)

The Application of Aluminum in Electric Science. (Die Verwendung des Aluminiums in der Elektrotechnik.) H. Schmitt. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 3, July-Aug. 1931, pages 253–260.

To-day, Al is used in some fields of electrical industry with great success; in Germany, for instance, more than 50% of the length of transmission lines for voltages from 30 to 200 KV are of Al. Its particular advantages over Cu are good mechanical properties together with its low specific weight, in particular the ratio of tensile strength to density which is, for the high-conductive, refinable Al alloys, considerably greater than for Cu. Furthermore, the low melting point and the ability to pour easily which, in certain cases, permits the Al to be cast directly into the slots of electrical machines without injury to the iron laminations. The insulating oxide film formed by the material itself is also an advantage. A few examples of these properties which are used in various fields are described and illustrated. Ha(9)

Aluminum Castings in the Electrical Industry. (Aluminiumguss in der Elektro-Industrie.) Schaumann. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 3, July-Aug. 1931, pages 284–292.

Numerous illustrations of parts for electrical machines and apparatus. Ha(9)

Small Sky Cars Entirely of Metal. William B. Stout. *Metal Progress*, Vol. 20, Sept. 1931, pages 40–43.

Describes small metal plane developed for the "average man" who wants to fly his own plane. WLC(9)

The Construction Development of Welded Parts in Steel Construction. (Beiträge zur konstruktiven Gestaltung von geschweissten Verbindungen im Stahlhochbau.) R. Ulbricht. *Stahl und Eisen*, Vol. 51, Feb. 26, 1931, pages 253–257.

Report 169 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The article reviews the latest developments in welding structural parts in building construction and notes the saving of money and time effected by the application of suitably rolled and shaped profiles. A new sheet beam is described. The advantages of welded constructions in comparison with riveted constructions are pointed out. GN(9)

The Construction of Laminated Poles. C. L. Szalanczy. *Metal Stampings*, Vol. 4, Feb. 1931, pages 145–148, 166.

Szalanczy divides the fabrication of stamped pole laminations into a sequence of 8 operations, 2 of which are considered here. First, he describes the spot welding of end plates and the special fixture employed in that operation. Then, he discusses the assembling and riveting operation for building up the laminations and end plates into a complete unit. An adjustable fixture used in a power press is fully described, which rivets one side of the pole at a time. A hydraulic press with interchangeable sets of inserts for larger pole assemblies is also described in detail. This press rivets both sides of the pole in one operation. JN(9)

Rope Strands for Long Suspension Span. D. B. STINEMAN. *Proceedings American Society of Civil Engineers*, Vol. 1, Sept. 1931, pages 1087–1091.
Crossing the Willamette River near its junction with the Columbia, the St. Johns Bridge, a 4 lane highway structure with a main span of 1027 ft., is the longest of any type west of Detroit. As to clear height, also, 205 ft., above navigable water, it sets a high record for under-clearance. Furthermore, it is the longest rope-strand suspension span in the world; all of the 8 longer ones are of the conventional parallel-wire construction. At the Trenton plant of the John A. Roebling's Sons Co., each of the 182 rope strands was manufactured to a length of about 2750 ft., Each strand was then pre-stressed to a total tension of 150,000 lbs. (one half of the ultimate strength) and held at this tension one half hr. The tension was then reduced to 70,000 lbs., corresponding to the average full dead-lead stress per strand in the structure. At this tension of 70,000 lbs., the strand was carefully measured to a calculated length, which varied somewhat according to its position in the cable. Corrections for temperature were included in this measurement. The strand was then cut and socketed, wound on a wooden reel, and shipped by boat to the site. The weight of each strand was 6$^1/_2$ tons. The 182 rope strands, each 1$^1/_2$ inches in diameter, have a total weight of nearly 1200 tons. For each cable, 91 twisted strands form a hexagon. This was filled out to a cylindrical section with segmental strips before the outside wrapping was applied. The hexagon cable had a major diameter of 11 galvanized rope strands (each 1$^1/_2$ inches in diameter) or 16$^1/_2$ inches before wrapping. This was given 2 coats of paint and then the segmented fillers were applied. The fillers consisted of Port Oxford cedar, cut into segmental strips 6 ft. long and treated by immersion for 20 min. in linseed oil at 200° F. When practically all the dead load was on the suspension, the cables, rounded out with the treated cedar fillers, were given their outside wrapping of No. 9 soft annealed double-galvanized wire. The structure cost $4,000,000, a saving of $42,000 over a parallel-wire design. WAT(9)

Arc Welding in Building Construction. P. N. VINTHER (Dallas Power & Light Co.). *Electrical Engineering*, Vol. 50, Oct. 1931, pages 785–787.
Data obtained during the construction of the tallest building erected to date using the electric arc welding process are discussed briefly. Outstanding advantages are: (1) almost complete absence of noise and (2) reduced steel tonnage required. WHB(9)

The Manufacture of Cast Iron Loud Speaker Horns. (Die Fabrikation von gusseisernen Lautsprechertrichtern.) W. SCHAEFER. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Apr. 10, 1931, page 304.
For quantity production, horns with the narrow part of cast iron of 3 mm. wall-thickness to which the wide part of sheet iron is fastened, proved to assure cheap production as well as good tone quality. Ha(9)

The Construction of Sea-Going Vessels by Electric Welding. GEORGE THURSTON. *Welder*, Vol. 3, Sept. 1931, pages 4–7.
The noted author points out in this article that the use of electric welding in ship building is progressing from day to day, particularly because of the impression which the small battleship, Deutschland, has made which proves that this method is entirely workable even for vessels of large tonnage and subject to severe stresses. The matter is discussed from the viewpoint of confidence in welding which does not yet exist generally but which should be deepened by further experiments; especially from the point of the workmen in the trade unions in England. Their strict distinctions of class of work not to be trespassed on by other men make it difficult to introduce electric welding. Ha(9)

A Tungsten Filament Alloyed with Thorium for Incandescent Electric Lamps. KWAN NISHIMOTO. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 24, 1931, pages 1–36.
The W-Th alloy is a solid solution. AHE(9)

Roller Bearings for Air Service. J. B. NEALEY. *American Machinist*, Vol. 74, Mar. 26, 1931, pages 491–492.
Bearing cages are made of duralumin. Steel for races and rollers is Swedish steel with 1.40–1.65% Cr, 0.025% maximum P, 0.02% maximum S. Describes heat treatment giving temperatures used. Treatment gives cages tensile strength of 62,000 lb./in.^{2}, yield point 30,000–36,000 lb./in.^{2}, and elongation 18–25% in 2 in. Brinell hardness 93–100. RHP(9)

Getting the Most Out of Die Castings. L. H. MORIN (Doehler Die Casting Co.). *Iron Age*, Vol. 128, Aug. 6, 1931, pages 376–377, 398.
The many uses of die castings to date have not exhausted the possibilities of this process in the mechanical field. Gives examples suggestive of the many possibilities of die cast machine elements. VSP(9)

Aluminum in the Construction of Large Current Condensers. (Aluminium im Starkstromkondensatorenbau.) L. LUX. *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 3, July-Aug. 1931, pages 261–262.
Up to 600 volts, condensers can be built up from Al foil with paper or oxide film dielectric. Ha(9)

Nickel in Rails. (Le nickel dans le chemins de fer.) F. RENAUD. *Aciers Speciaux, Métaux et Alliages*, Vol. 6, Apr. 1931, pages 179–189.
General discussion of use of Ni in railroad materials as well as in high Ni steels. European and American Ni steels used for railroads are compared. Mo is also added to a 2% Ni steel. GTM(9)

Operation of High Pressure Boilers. WM. F. RYAN. *Power Notes*, Vol. 17, Sept.-Oct. 1931, pages 1–5.
The article discusses, in general, the problems arising in the operation of high pressure steam boilers. One of the foremost among these is the feedwater purification to avoid troublesome formation of scale. The evaporator has very largely solved this question. Corrosion and embrittlement have been corrected by de-aerators and proper design of boilers; this has also taken care of the combination of pressure and temperature stress. False water levels are often due to incorrect bottom connection for the water column; it should always be so arranged as to drain toward the drum. Gage glasses should be of a good grade of glass and so mounted that it may expand without undue restriction. Ha(9)

Preparation and Properties of Carbide & Nitride Crucibles, with Comments on the Reactions of Carbides & Graphite with Metal Oxides. (Ueber die Darstellung und die Eigenschaften von Karbid- und Nitridtiegeln nebst einem Beitrag über die Reaktionen von Karbiden und Graphit mit Metalloxyden.) O. MEYER. Doktor-Ingenieur dissertation. Technische Hochschule, Aachen, July 1929, 30 pages.
Various Cr-C and Cr-C-Fe, Mo-C and Mo-C-Fe, W-C, Cr-W-C, mixtures were made up, and crucibles made of them; also, of SiC and Ti N. The attack upon these crucibles of molten Fe, Ni, Co, Mn, Cu, Al, Fe_2O_3, MnO, $2FeO \cdot SiO_2$, SiO_2, CaO : SiO_2, basic open-hearth and blast furnace slags, and a soda-lime glass, was studied. The carbide crucibles were attacked by the metals except Cu. The TiN crucible was not attacked by the metals, but was strongly attacked by the oxides. Fe_2O_3 attacked all the crucibles. The other oxides showed no attack on molybdenum carbide crucibles. Nothing was found in which the metals and the oxides could be simultaneously melted. HWG(9)

Steel Arches for Mines. SYDNEY C. MIFFLEN. *Iron & Steel of Canada*, Vol. 14, June 1931, pages 102–103.
An article, accompanied by 2 photographs, in which the steel arches used in colliery practice are described; particulars are given of the materials employed in their fabrication. OWE(9)

Fabrication of Automobile Springs. (Fabbricazione moderna delle molle a balestra per auto.) A. OREFFICE. *La Metallurgia Italiana*, Vol. 23, Sept. 1931, pages 833–836. 3 figures.
Brief mention of composition and properties of common spring steels, with photos of automatic heat-treating furnaces and controls. HWG(9)

One-Material Planes. CHAS. F. MCREYNOLDS. *Product Engineering*, Vol. 2, July 1931, page 319.
This passenger and mail plane is built up of flat sheet Alclad duralumin and is assembled by riveting. The shell is built by riveting together a number of longitudinal gores, all exactly alike and riveted to a series of lateral duralumin rings. The use of only one material reduces manufacturing cost. A few performance data are added. Ha(9)

Bi-metal Pistons. (Zweimetall-Kolben.) MAHLE. *Automobiltechnische Zeitschrift*, Vol. 34, Mar. 31, 1931, pages 205–208.
Under the designation of bi-metal pistons, the author includes only those in which the head is of one material, usually aluminum alloy, and the stem of another, usually cast iron or steel. He sets forth the reasons that gave rise to such constructions and describes about 20 different pistons of this type. "Why have these pistons not gained a foothold in the automotive industry in any country?" the author asks. He finds his answer in an analysis of the present aluminum piston, which he asserts has overcome the defects of the early light-alloy piston. These defects, unduly high thermal expansion and low wear resistance, having been obviated, the reason for the bi-metal piston no longer exists. WHB(9)

Novel and Interesting Tin Roof. K. G. LUNDIN. *Sheet Metal Worker*, Vol. 22, Aug. 21, 1931, pages 482–483.
Description of laying a tin roof of 150 × 76 ft. with sheets of 20 × 28 in. Work had to be done at a temperature of 97° F. Ha(9)

New Materials Will Cut Locomotive Repair Costs. C. A. BARBA. *Railway Mechanical Engineer*, Vol. 105, Oct. 1931, pages 483–487.
The author suggests that, instead of designing to take up wear, the attempt be made to eliminate it by using the special alloyed steels (especially nitrided steels) for repair work. The nitriding process is explained and its possible uses, particularly for locomotive parts, are discussed. Ha(9)

The Technique of Copper Roofing in Germany. (La technique des toitures en cuivre en Allemagne.) H. KUNITZ. *Cuivre et Laiton*, Vol. 4, July 15, 1931, pages 305–313; July 30, 1931, pages 327–331; Aug. 15, 1931, pages 353–355.
Details of connection of the copper sheets to walls, chimneys, gutters, etc., are given. The last installment describes the mounting and fastening of sheets, gutters, window sills. Profusely illustrated. Ha(9)

Casting Large Marine Propellers. WESLEY LAMBERT. *Metal Industry*, London, Vol. 38, May 8, 1931, page 480.
Specifications for large propellers requiring strengths of 40 tons in.^{2} are met by using manganese bronze. The β phase is preferred for propellers on ocean going vessels. PRK(9)

Latticed Metal. (Gittermetal.) CARL KRÖMER. *Maschinenkonstrukteur-Betriebstechnik*, Vol. 64, July 10, 1931, page 160.
In as much as the recent development of bearing metals has produced a solution by the introduction of latticed metals containing graphite, very satisfactory results have been obtained. The castings referred to are of the improved type, cast at 300° C., have a dimension of 0.2 mm. and have clean, smooth surfaces. MAB(9)

Application of Acid-Proof Materials in the Manufacture of Artificial Silk. (Anwendung säurebeständiger Werkstoffe in der Kunstseidenfabrik.) E. WURTZ. *Korrosion und Metallschutz*, Vol. 6, June 25, 1931, pages 21–23.
In the manufacture of artificial silk from viscose, the machines are subject to rapid corrosion by contact with acids or acid vapors. As hardly any material will stand up for a long time, a new non-metallic material by the name of Haveg has been developed by the Säureschutzgesellschaft in Berlin. It has a phenol basis like bakelite. It is readily machinable and can be brought into almost any shape. Another material is Aeterna of the Heddernheimer Kupferwerke, Frankfurt a.M. It is a bronze of very fine grain and a tensile strength of 75–88 kg./mm.^{2} at 200° C. It has a good resistance against sea water and sulphuric acid. Another material for similar purposes is called Thermisilid, made by Krupp, Essen, in several qualities which are resistant against hot lyes, nitric acid, ammonia, hydrogen peroxide and acetic acid. Also the silumin, an alloy with 13% Si of the Metallgesellschaft, Frankfurt a.M. is a good resisting material in the production of artificial silk. Ha(9)

1930 Airplane Design. *Aviation*, Vol. 30, Jan. 1931, pages 22–25.
All performance gains are due to aerodynamic refinement and decreased structural weight. Trend is toward the use of metal. Metal fuselage construction compared favorably in weight with present wooden structures. Riveted Al alloy is used. Stainless steel with electric spot welding is progressing. DTR(9)

Fabricating Heavy Electrical Plant. *Industrial Gases*, Vol. 12, Mar. 1931, pages 20–21.
Adoption of fabricated design in place of castings for parts of large electrical machines has come to fore. Electric arc, oxy-acetylene and gas welding are all used. Automatic oxy-acetylene shape cutting machines are described. DTR(9)

Aluminium in the Construction of Furniture. *Metal Industry*, London, Vol. 38, May 1, 1931, pages 457–458, 460; May 15, 1931, pages 507–508.
Aluminum furniture is distinguished because of its lightness, strength, durability, cleanliness and incombustibility. PRK(9)

Industrial Uses for Tungsten Plate. *Technology Review*, Vol. 33, July 1931, pages 454–455.
The discovery of a process by which a great variety of metals may be electropiated with W has been announced by Prof. Colin G. Fink of Columbia University. The advantages are that it has a high lustre, does not tarnish, has a high melting point, undergoes no appreciable oxidation at ordinary temperature and is resistant to acids. It is of great value to the chemical industries for resistance to heat and acids. MAB(9)

Light Metals for Bus-Chassis. (Leichtmetall für Omnibusaufbauten.) M. KÜHNAST. *Deutsche Motorzeitschrift*, Vol. 8, June 1931, pages 208–210.
The drawbacks of wood, steel and a combination of both for the overhead structure of busses are critically discussed and the utilization of duralumin yielding a saving in weight of about 40% is given. The complete design of a leading German bus manufacturing company is outlined. EF(9)

Bearing-Metals and Repair Work on Bearings. (Ueber Lagermetalle und Lagerreparaturen.) K. HAASE. *Deutsche Motorzeitschift*, Vol. 8, June 1931, page 226.
Controversial remarks on a paper by Schüler (*Deutsche Motorzeitschrift*, Vol. 8, No. 4, Apr. 1931, pages 146–148). The author advocates the usefulness of bearing metals containing lead and graphite, respectively, and states his own experience on repair methods. EF(9)

HEAT TREATMENT (10)

Precautions in Heat Treating High Speed Steel. *Houghton's Black & White*, Vol. 4, July 1931, pages 15–19.
The proper treatment of high speed steels, especially type 18–4–1, in forging, annealing, hardening and tempering is described in detail. Ha(10)

Effect of Heat Treating Firebox Plate and Flues in the Process of Manufacture. *Boiler Maker*, Vol. 30, Feb. 1930, pages 51–53.
Committee report of Master Boiler Makers' Association concerning relative merits of cold-drawn and hot-finished tubes; the conclusion is drawn that hot-finished tubes are more satisfactory for boiler and service. VVK(10)

Heat-Treating Terminology. *American Machinist*, Vol. 74, Jan. 29, 1931, page 219.
Definitions especially related to the ferrous alloys abstracted from the American Society for Steel Treating Handbook. They cover heat treatment, quenching, hardening, annealing, carburizing, case hardening, case, core and cyaniding. RHP(10)

Correct Heat Treatment Essential in Brass Forging and Hot Pressing. R. E. Falk. *Fuels & Furnaces*, Vol. 9, May 1931, pages 591–598.
The practice of forging and hot pressing, the proper sequence of operations, the correct heat treatment and temperature control are discussed fully and furnaces used in the work are described. Ha(10)

Dimensional Changes in High Speed Steel and Furnace Atmosphere. Correspondence from J. E. Hines (C. I. Hayes, Inc.). *Metals & Alloys*, Vol. 2, Sept. 1931, page 119.
The writer presents data indicating tentatively an effect on dimensional changes due to appearance of O_2 in the atmosphere. WLC(10)

The Mechanical Surface Treatment in the Manufacture of Automobiles. (Einiges aus der mechanischen Oberflächenbehandlung im Automobilbau.) Guido Prachtl. *Automobiltechnische Zeitschrift*, Vol. 34, Sept. 20, 1931, pages 575–579; Sept. 30, 1931, pages 610–611; Oct. 10, 1931, pages 634–636; Oct. 20, 1931, pages 663–665; Nov. 10, 1931, pages 711–712.
Numerous examples illustrate hardening, nitriding, carburization plants for parts of automobiles, the changes brought about by the various treatments are illustrated in diagrams for hardness, penetration depth, temperature of treatment. Polishing and grinding for tight fit and the equipment of several plants are described. Ha(10)

Flexibility in Heat Treating. *American Machinist*, Vol. 74, May 28, 1931, pages 818–820.
An installation which serves for carburizing and heat treating and can also be adapted for nitriding is described. Ha(10)

The Heat Treatment and Manufacture of Springs. E. F. Davis. *Fuels & Furnaces*, Vol. 9, Apr. 1931, pages 417–428; May 1931, pages 571–576.
The various kinds of steel used for helical and leaf springs, their chemical and physical properties, the processes of heat treating and annealing, alloy spring steels and defects in spring wire are discussed fully and tables of practical figures are given. In designing springs, the factor of safety should not be under 3; 5 or more is even better. The maximum fiber stress should never exceed 70,000 lbs./in.^{2}; for larger diameter wire, this should be reduced to 50,000–60,000 lbs./in.^{2} Ha(10)

The Heat Treatment and Manufacture of Automotive Shafts and Axles. E. F. Davis. *Fuels & Furnaces*, Vol. 9, June 1931, pages 663–669; July 1931, pages 807–812, 830; Aug. 1931, pages 905–910, 936.
The materials used and the processing and correct heat treatment for the desired physical characteristics are discussed. Ha(10)

Annealing (10b)

The Heat Treatment of Brass. H. M. St. John. *Fuels & Furnaces*, Vol. 9, July 1931, pages 787–794, 838.
The interrelation of the grain structure of brass and heat treatment and the relation between time and temperature annealing is discussed and the means of producing a suitable grain size are described. The rolling practice, the types of heating methods employed, the finishing processes and bright annealing are fully treated. Bright annealing can now be done successfully in a methanol atmosphere but the brass must be allowed to cool below its scaling temperature before it is quenched or exposed to air. The advantages obtained by bright annealing for further use are noted. Ha(10b)

Effect of Normalizing on Sheet Steel. Wm. F. McGarrity & H. V. Anderson. *Fuels & Furnaces*, Vol. 9, Oct. 1931, pages 1169–1170.
Investigation of the effect of normalizing on the properties and grain structure of automobile sheet steel as revealed by X-ray diffraction patterns, photomicrographs and Erichsen-tests gave the following results: (1) Increased soaking time allows the atomic planes to orient themselves into their normal alignment in the space lattice, thereby eliminating internal strain. The grain growth is slight. (2) An increased preheating period has no effect on the crystal structure. (3) Directional properties are not entirely eliminated even with a soaking time of 7 mins. at 1800° F. (4) No lattice dimensional changes take place from the heat treatment. (5) The length of the edge of the unit cube of Fe is found to be 2.89 A. U., corresponding favorably with the accepted value of 2.87 A. U. (6) A temperature of 1700–1750° F. is found to be most favorable for normalizing operations. Ha(10b)

Composition, Temperature, Time and Control Govern Short Anneal. Edwin Bremer. *Foundry*, Vol. 59, Sept. 1, 1931, pages 54–56, 58.
Discussion of results obtained by various investigators. From tests made by Diller, it appears that if composition is correct, the only thing essential to annealing is the heat. In commercial practice, the cycle has been modified to take into consideration such factors as variations in section thickness of castings, variations in composition of metal to be annealed, enlarged size of furnace and large mass of castings to be annealed in the furnace. The overhead electric furnace, rectangular in shape, is used. Uniformity of temperature in all parts of the furnace is essential so that all castings attain maximum temperature in the shortest time. Chemical composition also has considerable effect on shortening of the annealing cycle. VSP(10b)

A. G. A. Research in Bright Annealing Metals. R. J. Cowan. *American Gas Association Monthly*, Vol. 13, May 1931, pages 200, 201, 215.
The object of the research has been to devise ways of annealing metals in a gaseous atmosphere and still retain a bright surface. Distinction is made between those cases where the usual reducing gas may be used and those where definite chemical reactions must take place at the metal surface. The latter case is complicated by the fact that gases are evolved from metals when heated which are oxidizing to the metal, and in Zn bearing metals by the fact that Zn is highly volatile. Even in neutral or reducing gases the metal will be tarnished. The methanol process is described. It has been found that flue gas is unsuitable for bright annealing because of the high content of CO_2. However, if flue gas be made a carrier for methanol vapor and brought into an annealing chamber, the vapors, in dissociating under heat will react with the metal oxides and this reaction will take place regardless of the presence of certain other oxidizing gases. Photographs are given of a typical furnace installation for carrying on this process. RJC(10b)

Age-hardening in Carbon Steels Quenched below A_1 Point. R. YAMADA & K. YOKOYAMA. *Kinzoku no Kenkyu*, Sept. 1931, pages 480–495.

Rockwell hardness, tensile strength, elongation and contraction of area as well as electrical resistance and density were measured with C steels containing various percentage of C from 0.013 up to 0.9% which were quenched below A_1 point, aged at room temperature and tempered at various temperatures. The results of experiments are summarized as follows: Age-hardening in C steels quenched below A_1 point is closely related to the change of the solubility of C in α-iron below A_1 point. The increase in hardness is greater in low C steels than in high C steels. In 0.1% C steel, the increase of hardness is 30%. By quenching from 700° C., and 60% by aging at room temperature, as compared to an annealed state. (58.0% in the annealed state, 78.4% in the quenched state, 94.3% after aging for 330 hrs. in Rockwell B scale.) The change in tensile strength is nearly the same as in hardness. The hardness thus increased diminishes by tempering first rapidly and then slowly. Electrical resistance increases by aging; but decreases by tempering. Density increases only slightly. The age-hardening is explained in the following way: During aging at room temperature, C atoms in steel quenched below A_1 points move toward certain points within the lattice and thus concentrate themselves; this assemblage of C atoms causes the distortion of iron lattice and therefore the hardening of steels. By tempering, cementite molecules separate out in the boundary layers and above 250° C. the formation of its space lattice takes place, these processes resulting in the softening of the steel. KT(10f)

On the Aging of Hardened Carbon Steel. (Ueber die Alterung des gehärteten Kohlenstoffstahles.) S. STEINBERG & W. SUBOW. *Stahl und Eisen*, Vol. 51, July 16, 1931, pages 911–913.

After considering the results of previous investigations on the above subject, the authors report the findings of their own investigations which were carried on with a steel of C, 0.98%; Si, 0.19%; Mn, 0.43%; P, 0.026%; S, 0.01%. Machined specimens of this steel were quenched from 750° C. in water of room temperature and aged at room temperature, 75°, 100° and 125° C. for various times. In all cases, the hardness increased by aging. The increase of hardness is followed by a contraction. For practical purposes, it is suggested that water-quenched steel be aged for 1/2 hr. at 125° C. Hardness and toughness are increased while the internal stresses are diminished. GN(10f)

The Aging of Soft Steel after Deformation at 600°–700° C. (Die Alterung von weichem Flussstahl nach Verformungen bei 600° bis 700° C.) F. SAUERWALD. *Stahl und Eisen*, Vol. 51, Sept. 10, 1931, pages 1150–1151.

In order to study the above noted fact, a "notch-upsetting test" was made on a 0.1% C open hearth and a 0.1% Thomas steel. Both steels were known to show pronounced aging effects and were aged for various times after the deformation had been performed at temperatures between 600° and 700° C. The notch toughness was tested with a 10 mkg. Charpy tester. The results are as follows:

Material	Deformation temperature ° C	Time of aging	Notch toughness mkg./cm.² (room temperature)
Thomas steel	600	20 min.	4.3
		4 hrs.	4.1
		1 wk.	2.9
		3 mos.	2.7
	670	20 min.	4.7
		4 hrs.	4.3
		1 wk.	5.0
		3 mos.	3.7
	680	20 min.	5.0
		4 hrs.	4.9
		1 wk.	5.0
		3 mos.	3.8
Open Hearth steel	600	20 min.	8.2
		40 min.	7.5–7.5
		5 hrs.	7.5
		24 hrs.	7.2–5.9
		1 wk.	7.0
		3 mos.	6.2

There is a remarkable decrease of notch toughness with the increase of aging time after the deformation at 600° C. This is much more pronounced with Thomas steel than with open hearth steel. The aging effects are less pronounced at the higher temperatures of deformation. GN(10f)

The Aging of Steel. ALBERT SAUVEUR. *Fuels & Furnaces*, Vol. 9, Sept. 1931, pages 1019–1024.

In the aging of metals, particularly that of steel, 2 types of aging must be considered: aging after quenching and aging after cold work deformation. Comparing the equilibrium diagrams of duralumin and C-Fe, the author sees the best explanation for the aging phenomenon in the Fe_3C precipitation which results, after quenching, in increased hardness. The specific effects of cold working, i. e., increase of strength, elastic limit and hardness but decreased ductility, are intensified by rest at room temperature; this can, therefore, be considered as aging. And, just as in aging after quenching, the changes due to aging after cold work deformation may be greatly hastened by heating to relatively low temperatures, generally not exceeding 400° C. in the case of Fe-C alloys. This effect can also be ascribed, like that after quenching, to the precipitation of a solute on account of a distortion of the space lattice of the solvent by which it is rendered less capable of retaining the solute in solution. This would mean that an undisturbed lattice can retain, in solution, a greater amount of the solute; a distorted lattice behaves in this respect like a supersaturated solution. But, while in the case of quenching Fe_3C is precipitated, in the case of cold work deformation it is FeO. This theory would also explain the blue heat brittleness phenomenon often observed after cold working. But the author does not think that sufficient evidence of aging caused by precipitation after cold work deformation has been adduced to be fully conclusive. Ha(10f)

On the Age-Hardening Mechanism in Aluminum Copper Alloys. K. HONDA & S. KOKUBO. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 621–633. 15 figures, 20 references.

The age hardening is ascribed primarily to lattice distortion rather than to the presence of $CuAl_2$ particles in colloidal dispersion. On Honda's theory, the process of lattice distortion preponderates up to an aging temperature of 200° C. At 250° C., the distortion has been eliminated and the precipitation process is at its maximum. Coagulation then follows and finally redissolution. The relative magnitude of these processes and the amount to which they overlap is alleged to explain the hardness-temperature curve. HWG(10f)

Malleableizing (10g)

Dilation Bar to Control Anneal of White Iron. Correspondence from A. PORTEVIN, Paris, France. *Metal Progress*. Vol. 20, No. 5, Nov. 1931, pages 77–78.

The writer proposes a dilatometric method of control of annealing time in malleableizing. A pilot bar of the same material being annealed is followed in its expansion due to graphitization and will indicate, by no further expansion, the end point of the anneal. WLC(10g)

JOINING OF METALS & ALLOYS (11)

Welding & Cutting (11c)

Welding in Shipbuilding. A. T. WALL. *Welding Journal*, Vol. 28, Oct. 1931, pages 302–303.

Lecture given before members of the British Acetylene Association and the Institution of Welding Engineers, Sept. 23rd, 1931. The author states that during the past 15 years there has been little progress in welding as applied to shipbuilding. He suggests fear as one of the causes. In order to further use of welding, the author suggests starting a shipyard entirely for welding. It is pointed out that the strongest ordinary riveted joint is about 75% efficient, whereas a 100% joint can be made by the use of welding. Other advantages are saving weight at the joint, continuous longitudinal and transverse strength, better distribution of material, ease of stiffening plates and perfect oil and water tight work. TEJ(11c)

An Improved Product by the Use of Bronze Welding. H. F. REINHARD. *Journal American Welding Society*, Vol. 10, Oct. 1931, pages 5–8.

Paper presented at the Fall Meeting of the American Welding Society in Boston, Sept. 1931. The author tells about the use of bronze welding as applied to light gage galvanized sheet steel and iron in the fabrication of an acetylene generator, and how the strength, life, gas and water-tightness and resistance to shipping and handling damage were greatly increased by the use of bronze welding. TEJ(11c)

Gas-Welding and Electro-Welding Problems. (Neuzeitliche Gas- und Elektro-Flammverschmelzungs- und Durchbrennverfahren.) F. KRYNES. *Zeitschrift des Oesterreichischen Ingenieur- und Architekten Verein*, Vol. 83, Oct. 2, 1931, pages 300–302.

The author summarizes the various lectures delivered at meetings of the Oesterreichischer Ingenieur- & Architekten Verein referring to problems in the fields of welding. EF(11c)

The Influence of Copper Content on the Fusion Weldability of Mild Effervescent Steel. (Ueber den Einfluss des Kupfergehalts auf die Schmelzschweissbarkeit von unruhig vergossenem weichem Flussstahl.) K. L. ZEYEN & H. MEHL. *Schmelzschweissung*, Vol. 10, Nov. 1931, pages 264–268.

A small addition of Cu is known to increase corrosion resistance, elastic limit and strength in hot working. The present investigation was made to determine whether, and in which manner, the fusion-weldability (with which resistance butt welding, is also included) is influenced by Cu. The conclusion is that low C effervescent mild steel can be butt welded with Cu contents up to 2%. The tensile test showed, in all cases of welded—not heat treated—samples, more than 90% of the tensile strength of the full material. The bending angle in the bending tests decreased considerably in the samples with Cu above 1%. Samples made of bare, not coppered, welding wire by electric arc welding showed in the tensile test values of over 80% of the full material up to 2% Cu. Samples made by gas-fusion welding gave, only for Cu contents below 1% tensile strengths of more than 80% of the full material. The samples with higher Cu contents showed, at the edge of the welded seam, fine deposits which had to be assumed to be metallic or oxidized copper as they were observed only on high coppered steels. 9 references. Ha(11c)

New Series of Tests on Flame-Cut Wind Connections. OTIS E. HOVEY. *Engineering News Record*, Vol. 106, April 30, 1931, pages 729–730.

Recent tests made to ascertain whether flame-cutting structural details for wind connections for building frames is reliable confirmed the assumption that no cracks occurred in any of the flame-cut or flame-cut and planed edges and that the load deflection values and stress distribution were about the same for the different types of specimens. No brittleness developed, proving that flame-cut connections are entirely reliable and satisfactory. Ha(11c)

Autogenous Welding and Metallography. (Die autogene Schweissung und die Metallographie.) A. PORTEVIN. *Schmelzschweissung*, Vol. 10, Nov. 1931, page 262.

The rather complex phenomena of physical and chemical nature of welding and their bearing on changes of the material are discussed. Injurious consequences can always be eliminated or compensated for by counteracting factors which must be physical, chemical or mechanical according to the nature of the injurious factor. Ha(11c)

Electron Metal and Its Welding in the Manufacture of Automobiles. (Elektronmetall und dessen Schweissung im Fahrzeugbau.) H. A. HORN & KARL TEWES. *Automobiltechnische Zeitschrift*, Vol. 34, Nov. 30, 1931, pages 762–765.

The welding of electron alloys, which are alloys of about 98% Mg with small amounts of Al, Zn and Mn, is now possible without difficulty. It is done best with the oxy-acetylene flame which must be adjusted absolutely neutral. The flux is applied as a thin, liquid solution in sufficient amount to prevent inflammation of the electron. It usually contains Li; chlorides should be avoided because they attack electron strongly. As electron warps greatly under the flame, it must be carefully pinned down; the distance of pinning points should be between 20 and 50 mm. The flux must be removed carefully after welding because it promotes corrosion. Examples of pipes, chains, frames, etc. are illustrated. It is important that the parts be uniformly preheated to 300° C. Ha(11c)

Welded Joint Carries Column Load of 380 Tons in Lobby Alteration Job. F. P. MCKIBBEN. *Engineering News Record*, Vol. 107, Sept. 3, 1931, pages 374–376.

A detailed description is given of a third field-welded addition to the du Pont building in Wilmington, Del., of several stories, and lobby alterations. A double truss was inserted to pick up a heavy column load at the second floor by a special welded connection. Welding data are added. Ha(11c)

Strength of Structural Welds. H. M. PRIEST. *Engineering News Record*, Vol. 107, Sept. 17, 1931, pages 436–440.

The report of the 5-yr. research program of the American Bureau of Welding is reproduced in detail. 2500 specimens involving 55 forms of joints were welded by 39 fabricators and tested in 24 laboratories. It is stated that the working stresses accepted at present are justified and that satisfactory uniformity in the strength of welds made commercially by any reputable fabricator can be expected. Testing method, welder performance, safety factors are discussed and general recommendations and suggestions for further research are added. Ha(11c)

Fusion Welding in Iron Structure. (Die autogene Schweissung im Eisenhochbau.) C. F. KEEL. *Die Schmelzschweissung*, Vol. 10, Oct. 1931, pages 237–242.

Investigations have proved that autogenous welding can easily be applied in building high structures; butt welds and lap welds can be made with right hand welding. The designer must take care of the special requirements of welding practice by using proper corner sheets, re-enforcing plates, etc. Fusion welded parts should be properly designed under the coöperation of the mechanical designer and the welding expert. Ha(11c)

The Welding of Chrome-Alloy Sheet Metals. G. VAN DYKE. *Metal Stampings*, Vol. 4, Aug. 1931, pages 643–644.

Allegheny metal, a Cr-Ni-Fe alloy (18% Cr, 8% Ni, 0.15–0.06% C), can be welded by electric, gas or spot processes. Care must be taken that, in welding, neither the analysis nor the structure of the metal be changed. The necessary requirements for the flame of gas or acetylene, fluxes used, the regulation of the arc and the temperatures to be observed are described briefly. Ha(11c)

Electric Welding of a Gas-Storage-Tank. **(Reparatur von Gasbehältern mittels elektrischer Schweissung.)** HOHLBEIN. *Gas und Wasserfach*, Vol. 74, May 9, 1931, pages 432–434.

Outlines the electric welding repair work performed on the tray of a 1500 $m.^3$ gas storage tank. See *Metals & Alloys*, Vol. 2, Nov. 1931, page 266. EF(11c)

Effect of Coating of Welding Electrodes upon the Strength of Welds. **(Einfluss von Umwicklung der Schweissstäbe auf die Festigkeit der Schweiss.)** F. RAPATZ. *Stahl und Eisen*, Vol. 51, July 9, 1931, pages 888–889.

Abstract of a paper by K. Baumgärtel in Forschungsarbeiten auf dem Gebeite des Ingenieure Wesens, Publication 336, 1930, pages 1–33. The results of welding tests with coated and uncoated electrodes are summarized. GN(11c)

Large Welded Everdur Pressure Vessels. MARSELIS POWELL & I. T. HOOK. *Journal American Welding Society*, Vol. 10, Sept. 1931, pages 39–47.

Paper presented before the Fall Meeting of the American Welding Society in Boston, Sept. 1931. Photomicrographs show Everdur weld structures produced under various conditions of hammering and annealing. Best annealing temperature was found to be 650° C. Results of a number of tensile tests of welds are given. The authors then describe the fabrication and testing of 3 large arc welded Everdur pressure vessels, one 500 gal. and two 10,000 gal., designed for a working pressure of 100 $lbs./in.^2$ Longitudinal and girth seams were welded with $^5/_{32}$" Everdur electrode using reversed polarity at 190 amperes. These were butt welds, single 90° V for $^1/_4$" plate and double V for $^1/_2$". Cold working of weld metal was done with air hammers and annealing with gas torches. Hydraulic tests were made at twice the working pressure. TEJ(11c)

Copper Welding Solves Refinery Problem. DONALD R. PRATT. *Journal American Welding Society*, Vol. 10, Aug. 1931, pages 12–13.

A problem in corrosion of refinery still heads and piping, due to the action of hot zinc chloride, was solved by welding in a lining of Cu by means of the oxy-acetylene process. TEJ(11c)

Steel Foundry Welding. V. GORDON PIERSON. *Edgar Allen News*, Vol. 10, Sept. 1931, pages 952–955.

Includes discussion. Particular reference is made to welds on boilers, discovery of defects and tests, requirements in material. Micrographs illustrate the points in question. Ha(11c)

The Development of Electric Arc Welding in Japan. TAKESI OKAMOTO. *Journal American Welding Society*, Vol. 10, July 1931, pages 33–37.

Condensed from a paper presented by the author before the World Engineering Congress in Tokyo, Oct. 1929. A review of the progress made in electric arc welding in Japan during and after the war, both in research and welding applications. Use of arc welding has been greatly extended in shipbuilding, construction of penstocks, pipe, storage tanks, constructional and repair work in railway shops, foundries, and machine shops, as well as in the erection of steel structures. Electrode coatings were investigated, and electrodes developed for arc welding, cast Fe brass, gunmetal, Al alloys and mild steel. Arc welds made in H were found to be superior in regard to density, tensile strength, ductility and forging qualities. The author also includes a review of his recently published paper, "Theoretical and Experimental Research on Electric Resistance Welding," Memoirs of the College of Engineering of Kyoto Imperial University, Vol. 6, No. 1. TEJ(11c)

Resistance Welding of Metal Fabric. W. T. OBER. *Journal American Welding Society*, Vol. 10, Sept. 1931, pages 50–52.

Paper presented before the Fall Meeting of the American Welding Society in Boston, Sept. 1931. A description of automatic machinery used for resistance welding of steel fabric such as concrete road reinforcement. TEJ(11c)

Steel Foundry Welding. V. GORDON PEARSON. *Edgar Allen News*, Vol. 10, Aug. 1931, pages 926–930.

A general discussion of conditions in a foundry. The inspection staff should be especially trained in judging, testing and applying welding for repairs, maintenance work, etc. The importance of employing responsible welders and of selecting the proper methods is stressed. Ha(11c)

Large Diameter Pipe Arc Welded for Water Distribution. VINCENT P. MARRAN. *Journal American Welding Society*, Vol. 10, Aug. 1931, pages 5–9.

A description of a process of fabricating large diameter pipe by means of automatic metal arc welding. The author discusses selection of raw material, preparation of the edges for welding, forming and assembling, the welding process, cleaning the surface and coating the pipe. Tests of welds and welded vessels are described. Photographs of equipment used are included. TEJ(11c)

Hydrogen-Welding Now Automatically Controllable. S. MARTIN, JR. (General Electric Co.). *Electrical World*, Vol. 98, Sept. 26, 1931, page 561.

Welding automatically with the atomic H flame requires the maintenance of a definite size flame in a fixed plane between 2 slowly consuming tungsten electrodes. The relation of the fringe of the flame and the work is fixed mechanically. The control system is illustrated. When the start button is pushed, the coil of the line contactor and the coil of the H solenoid valve are energized. These apply power to the electrodes through the reactor and turn on the H gas, respectively. WHB(11c)

Welding Corrosion-Resistant Steels. W. D. MACLEOD. *American Machinist*, Vol. 74, Mar. 19, 1931, page 472.

Discussion of an article of the same title by E. J. Tangerman in American Machinist, Vol. 73, Sept. 18, 1930, page 485. This article states that Ni-Cr-Fe alloys containing 17–25% Cr and 7–12% Ni require no heat treatment for welding. It is true that they do not become brittle due to air hardening but they are subject to weld decay. To prevent this, the whole welded article must be heated to 1050–1100° C. and cooled rapidly. RHP(11c)

Welded Pipe and Fittings in Heating Installations. FRED J. MAEUER. *Journal American Welding Society*, Vol. 10, Sept. 1931, pages 5-13.

Paper presented before the Fall Meeting of the American Welding Society in Boston, Sept. 1931. Welding of pipe in heating installations is now accepted by architects, building owners, heating contractors, plumbers and steam-fitters as standard practice. Approximately 175 vocational training schools in the United States are teaching pipe welding. Advantages of welded pipe installations are given. Includes 18 sketches and illustrations. TEJ(11c)

Welding Monel Metal for the Construction of Chemical Apparatus. **(Ueber das Schweissen von Monel-Metall im chemischen Apparatebau.)** RUD. MÜLLER. *Die Chemische Fabrik*, Vol. 4, July 1931, pages 310–312.

Contains 2 references. Monel metal has great affinity for O when molten, forming CuO. With proper care, it can be electric arc welded with coated Monel metal wire. The coating consists of Mg-Mn-Si or Ti-Ca alloy. The work should be negative and held together with clamps to prevent warping. The edges should be champfered. Monel metal can also be welded by the atomic H, electric resistance, spot, hammer and gas processes. When gas welding, a neutral or slightly reducing flame should be used. Cleanliness of the joint is essential. An aqueous solution of equal parts of boric acid and borax is sometimes used as flux, but a flux is not necessary. 100% tensile strength, good ductility and corrosion resistance are obtained in the joint. CEM(11c)

WORKING OF METALS & ALLOYS (12)

Melting & Refining (12a)

Contribution to the Explanation of Metallic Volatilization Processes (Beitrag zur Deutung der Metallverflüchtigungsprozesse). Ilja Westermann. *Metall und Erz*, Vol. 28, May 1931, pages 214–217.
2 references. When Pb is melted in a cupel and heated, PbO is formed and part of it is absorbed by the cupel, part of it volatilizes. The temperature of the lead increases over that of surrounding matter. As the volume diminishes the proportion of exposed surface to surface touching the cupel increases and the heat is not conducted away as rapidly. To prove this a test was made in a specially constructed muffle using a thermocouple to measure the furnace temperature and an optical pyrometer through a window in the top for the temperature of the lead. The proportions of PbO volatilized and absorbed were found by determining PbO in the cupels after the tests. It was found that the proportion volatilized decreased with increase in size of sample. With 10 gm. sample 74% volatilized, with .1 gm. 1%. When bronze is melted in a converter without coke a very small part of the tin volatilizes and part of it remains as copper stannate. This is explained by the small surface of tin exposed. When bronze is heated with coke most of the tin volatilizes according to the following steps: Sn is oxidized to SnO_2 by O_2 in the air, SnO_2 is reduced by the solid C to Sn in small particles, the small Sn particles are oxidized to SnO_2 by O_2 and volatilized, and the small SnO_2 particles are removed by the stream of gas. CEM(12a)

Two-Cycle Anneal for Malleable Iron. Correspondence from T. Kikuta, Sendai, Japan. *Metal Progress*, Vol. 20, Oct. 1931, pages 86–88.
The writer reports the results of experiments in electric melting supplemented with a cupola for the production of white cast iron. A 2-cycle anneal without packing material is described for the complete graphitization of white iron. WLC(12a)

Steel Quality as a Matter of Furnace Control. *Iron Age*, Vol. 127, June 11, 1931, pages 1902–1904.
From a report of the Open Hearth Committee of the American Institute of Mining and Metallurgical Engineers, May 21–28, 1931. Deals particularly with inclusions and segregation. Control of the amount of Fe_2O_3 going into the slag is controlled by melting in an atmosphere which is slightly oxidizing, according to Prof. Trinks. Otherwise, there is an excess of O in the early part of the flame and over oxidation of the steel results. Experiments show a little more N in killed steel than in rimmed steel. VSP(12a)

Obtaining Clean Steel from the Acid Open-Hearth. C. H. Herty, Jr. & J. E. Jacobs. *Rolling Mill Journal*, Vol. 5, Feb. 1931, page 106.
Abstract of a paper presented at the Western Metal Congress, week of Feb. 16. See *Metals & Alloys*, Vol. 2, Oct. 1931, page 224. JN(12a)

An Application of the Triangular Co-ordinate System for the Graphic Determination of the Burden for Remelting Furnaces (Eine Anwendung des Dreieckskoordinatensystems auf die graphischen Gattierungsberechnungen für Umschmelzöfen). P. Schmidthuysen. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Oct. 9, 1931, pages 800–803.
The author develops a new means of calculating the burden on the basis of 3 single elements, which determines in a simple graphical manner the amount of the individual materials to be melted together. The method is illustrated and explained by means of several examples. Ha(12a)

Iron as Fuel in Open Hearth Refining Processes (Das Eisen als Heizstoff bei den Frischverfahren von offenen Herdflammofen). F. Wüst. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, Mining & Metallurgy, Part 1, pages 463–479.
One hundred and thirty to 200 lbs. of iron are burnt by the furnace gases per ton of steel made. Tables of oxygen balances are given. HWG(12a)

Debismuthising Lead with Calcium. *Metal Industry*, London, Vol. 38, May 15, 1931, pages 503–504.
Abstract of a paper read before Electrochemical Society, Birmingham, Ala., Apr. 23–25, 1931. If Ca is added to Pb at 482° C., a dross is formed removing Bi and scavenging the last traces of As, Sb, Ag, Cu, but not Sn. Some Ca remains to harden the Pb unless removed by blowing with steam or Cl. The most economical use is with lead having 0.5% Bi. See *Metals & Alloys*, Vol. 2, May 1931, page 105. PRK(12a)

Practice in Making Duplex Steel. J. E. Carlin. *Transactions American Society for Steel Treating*, Vol. 17, May 1930, pages 631–637.

Production of High Grade Steels in High-Frequency Furnaces (Erzeugung von Edelstählen in Hochfrequenzöfen). *Elektrotechnische Zeitschrift*, Vol. 52, July 2, 1931, pages 875–877; *Metallurgist*, Nov. 1930, pages 166–167.
Extended abstract of "Die Erzeugung von Edelstählen im kernlosen Induktionsofen" by O. Dörrenberg & N. Broglio, Report No. 183 of the Steel Works Committee of the Verein deutscher Eisenhüttenleute published in *Stahl und Eisen*, Vol. 50, May 8, 1930, page 617. See *Metals & Alloys*, Vol. 1, Sept. 1930, page 736. Ha+VVK(12a)

Institute of Metals (London Section). *Metal Industry*, London, Vol. 38, Apr. 24, 1931, pages 429–431; May 1, 1931, page 452.
An open discussion on the remelting of metals and the use of scrap. PRK(12a)

Melting Steel in a Brackelsberg Furnace. P. Bardenheuer. *Heat Treating & Forging*, Vol. 17, Feb. 1931, pages 177–179.
See *Metals & Alloys*, Vol. 2, Feb. 1931, page 42. Ha(12a)

Production and Heat Treatment of Alloy Steels. R. A. Bull (Electric Steel Founders Research Group). *Metals & Alloys*, Vol. 2, Sept. 1931, pages 101–105.
The utility of the electric furnace for the production of small heats of special steels has made possible development of such material. The author comments on the impressiv properties obtainable by proper heat treatment of common steel castings. Development of composition, heat treatment and specification for alloy steel casting is discussed. The question of design of castings to avoid shrinkage troubles and oth r points to guard against in production of alloy castings are discussed. WLC(12a)

Casting & Solidification (12b)

Some Notes on Teeming Speeds of Ingots. A. Jackson. *Iron & Coal Trades Review*, Vol. 122, Feb. 13, 1931, pages 277–278.
The following results can be summarized from tests to find the relation of pouring speed of ingots with varying types of nozzles and the relation of the speed to the quality of ingots produced: a suitable pouring speed for the production of sound ingots seems to be 120 secs. with an absolute minimum of 100 secs. For this reason, other than fireclay pots should be used because about the first 20 or 25 tons out of 80 are above this speed. The only choice at present seems to be the magnesite-ring type of pot. If an ideal pot giving a straight horizontal line teeming rate could be made, teeming time could be saved. A fireclay nozzle with a magnesite ring has a fairly good life. See also *Metals & Alloys*, Vol. 2, July 1931, page 135. Ha(12b)

What Size Should the Steel Ingot Be? Joseph Miller. *Iron Age*, Vol. 128, Aug. 6, 1931, pages 364–365.
Determination of sizes into which ingots are to be cast is first consideration in steel mill practice. Ability to cut the ingot product to proper size avoiding shorts, is one of the problems. Determination of top and bottom crops depends upon the specifications and quality desired in rolled product. It is customary to cast high C and other high metalloid steels in ingots of moderate size, and rectangular instead of square, to hasten solidification and to arrest segregation of C, P and S. Large ingots are likely to crack due to unequal cooling strains. Considers also factors influencing ingot design. VSP(12b)

Flexibility of Continuous Molding. (Unité de moulage continu.) J. Mort. *Revue Fonderie Moderne*, Vol. 25, Aug. 25, 1931, pages 301–303.
The author sees the greatest disadvantage of continuous molding and casting installations in their lack of flexibility to adapt them to changing conditions. He emphasizes the fact that they should be installed only where conditions can be considered as stable for some time to come. An installation is described where pieces of 2000 × 1200 × 250 mm. can be placed on the conveyor which is able to carry 16 tons total weight. This unit is operated by 7 men. The daily production in 8 hrs. averages 100 sections of radiators and similar pieces of 85–150 kg. each. The space taken by the installation is 35 m. long, 25.856 m. wide and 11.86 m. high. HA(12b)

The Flotation of Graphite in Cast-Iron. A. L. Norbury & C. Rowley, *Bulletin British Cast Iron Research Association*, Vol. 3, July 1931, No. 1, pages 7–9.
Analyses of the total C content of gray pig iron at various points from the top to the bottom of the face of the fractured pig show that the graphite floats upward as the pig solidifies. Several specimens had 0.27% more C in the top part than at the bottom where the amount of C was about 3.5%. The tests also support the modern view that the graphite is deposited directly from the melt and is not a decomposition product of solidified white iron. The method of sampling and testing is described. Ha(12b)

Wall-Thickness Sensitive Cast Iron. (Ueber wandstärkenempfindliches Gusseisen.) R. Mitsche. *Giesserei mit Giesserei-Zeitung*, Vol. 18, July 3, 1931, pages 537–539.
The wall-thickness sensitivity is defined by the author as the property of a cast iron alloy of assuming, at different cooling velocities, more or less pronounced differences in the formation of the structure and, consequently, in the tensile properties. The greater the differences at a certain change of the cooling velocity are, the more wall-thickness-sensitive the alloy is. The influences which determine this sensitivity have not yet been fully elucidated. They are discussed and a qualitative test is suggested for their determination. This test consists of casting a small sample of such dimensions that the cooling velocities in the different parts of the sample do not differ too much. This sample is examined microscopically. An example is given and 5 references are cited. Ha(12b)

The Casting of Best Ingots from the Point of View of Forging (La coulée des meilleurs lingots en vue du forgeage). H. H. Ashdown. *Revue Fonderie Moderne*, Vol. 25, Sept. 10, 1931, pages 335–336.
See "Steel Ingots," *Metals & Alloys*, Vol. 2, July 1931, page 135. Ha(12b)

The Ingot Phase in the Manufacture of Rolled Steel Products. Part VIII. John H. Hruska. *Rolling Mill Journal*, Vol. 5, Feb. 1931, pages 129–130.
A pronounced fibrous structure is undesirable in most steels. This structure may be produced experimentally by adding powdered slag of acid character to steel. The fibers invariably cover the entire cross-section of the fracture. Woody structures, however, are usually found only near the middle of the fracture. These portions contain higher proportions of basic constituents. Slaty steels show well pronounced layers of a smoother ferrous material which are high in C, P, and S content. JN(12b)

Permanent Molds for Zinc Alloy Castings. Edw. Heller. *Machinery*, Vol. 37, July 1931, pages 829–831.
2 examples for quantity production are described. The molds are heated to 500–550° F. before casting. Ha(12b)

Solidification and Crystallization of Steel Ingots; Influence of Casting Temperature and the Undercooling Capacity of the Steel. B. Matuschka. *Iron and Coal Trades Review*, Vol. 123, Oct. 2, 1931, pages 485–487.
The solidification and crystallization of steel ingots are absolutely regular phenomena. The external conditions which initiate them and cause them to continue are determined by the cooling of the mold. The internal solidification conditions determine the solidification and crystallization in the ingot under given conditions of heat dissipation by the mold. They are principally influenced by the casting temperature and the under-cooling capacity of the steel. The paramount importance of one of the factors is determined by the composition and the physical and crystallographic properties of the steel. In all cases, a low casting temperature and maximum purity make for finer primary crystallization and less segregation, which means improved quality because of increased uniformity. X-ray photographs illustrate the freezing of a 350 kg. ingot. Ha(12b)

A Contribution to the Study of the Fluidity of Metals. (Beitrag zum Studium der Dünnflüssigkeit der Metalle.) U. Gabino. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Nov. 6, 1931, page 868.
The fluidity of a metal is defined as that property of filling a mold more or less completely. The relation between fluidity and temperature depends on the chemical composition of the steel (as for all metals) and on the chemical reactions at high temperatures between the metal and the materials of the mold. The different influences are discussed and the best pouring conditions are determined. It is better to dry the molds before pouring. Ha(12b)

The Calculation of the Processes of Cooling and Freezing of Liquid Metal. II. (Die rechnerische Behandlung der Abkühlungs- und Erstarrungsvorgänge bei flüssigem Metall. II.) C. Schwarz. *Archiv für Eisenhüttenwesen*, Vol. 5, Oct. 1931, pages 177–191.
Report 217 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. Includes discussion. The paper continues the first part of the investigation by giving some more exact calculation methods on the freezing conditions of steel ingots. The calculations take particularly into account the split which is present between steel and mold wall when the molds are coated or which appears as soon as the steel in the mold starts freezing. A comparative calculation of the cooling conditions of an ingot poured under normal conditions of production and of an ingot pressed according to the Harmet method shows the differences as to velocity of freezing and distribution of temperature in mold and ingot. The results of actual tests are plotted in diagrams which clearly indicate the above relations. The paper finally points out that it will be necessary to introduce the velocity of freezing in studying processes of crystallizatiion. Number of nuclei and velocity of crystallization are not sufficient to get a proper insight into crystallization. GN(12b)

Blow Holes in Aluminum Sand Castings. II. The Appearance on Metals Previously Exposed to Corroding Influences. (Undichtigkeiten in Aluminium Sandguss. II. Teil. Die Erscheindungen an Metall, das vorher korrodierenden Wirkungen ausgesetzt war.) G. Hanson & I. G. Slater. *Korrosion und Metallschutz*, Vol. 7, Oct. 1931, page 250.
Reference is made to a lecture at the 24th General Meeting of the Institute of Metals, Zurich, September 1931. EF(12b)

Reciprocal Action between Steel Ingot and Mold. (**Action réciproque entre lingot d'acier et lingotiére.**) A. McCance. *Revue Fonderie Moderne*, Vol. 25, Aug. 25, 1931, pages 317–318.

The article explains the phenomena of mutual heating and cooling effects when a cast iron mold is filled with hot metal; the condition of the external skin of the ingot as dependent on the thickness; and dimensions of the mold. Three zones of this external layer are distinguished: the first, of about 3 mm. thickness of very fine crystals, is formed during the first few seconds of pouring; the second zone is formed while the heat exchange drops from 15 to 4 cal./sec.; and the third zone, below 4 cal./sec. Coloring (12m)

Black Coloring of Iron and Steel. (**Schwarzfärben von Eisen und Stahl.**) K. Schuch. *Oberflächentechnik*, Vol. 8, Sept. 1, 1931, pages 186–187.

A description of several methods. Conversion of the surface, first, in iron oxide, then, in magnetic oxide of iron at high temperature. Recipes for black oxidizing are given, as well as for a black arsenic deposit on iron. Ha(12m)

Brown Colorings on Brass and Copper. (**Braunfärbungen auf Messing und Kupfer.**) K. Schuch. *Oberflächentechnik*, Vol. 18, Aug. 18, 1931, pages 176–177.

Several recipes are given for liquids or pastes which give pleasing brown to brownish-green surfaces in art metal work. Ha(12m)

Spinning (12p)

How to Spin a Copper Tea Urn. William Mason. *Metal Industry*, N. Y., Vol. 29, May 1931, pages 199–200.

A detailed description of the operation involved in spinning a tea urn out of 0.040 in. copper. PRK(12p)

DEFECTS (13)

Remarkable Effect of a Pipe in an Angle Shape. (**Bemerkenswerte Wirkung eines Lunkers in einem Winkeleisen.**) F. Rötscher. *Stahl und Eisen*, Vol. 51, Apr. 23, 1931, page 521.

The widening of a pipe in the angle shape which was investigated was found to be due to the evaporation of water which had penetrated into the pipe. GN(13)

An Investigation of Steels for Aircraft Engine Valve Springs. A. Swan, H. Sutton & W. D. Douglas. *Engineer*, Vol. 151, Feb. 27, 1931, pages 231–232; *Engineering*, Vol. 131, Feb. 27, 1931, pages 314–316; Mar. 13, 1931, pages 374–376.

Condensed from paper read before the Institution of Mechanical Engineers, Feb. 20, 1931. See also discussion in Engineering, Vol. 131, Feb. 27, 1931, pages 307–308. LFM(13)

Criticism of Crankshaft Fractures. (**Beurteilung von Kurbelwellenbrüchen.**) E. A. Wedemeyer. *Automobiltechnische Zeitschrift*, Vol. 34, July 20, 1931, pages 472–475.

A series of fractured crankshafts is discussed with regard to the kind of fracture (bending fracture or torsion fracture) and the causes for them explained. They are: notch effect due to sharp corners, additional bending moments due to wear of bearings, warping of the shaft due to defective alignment, defective design (outside flywheel), defective materials. Fracture due to torsional vibrations is particularly discussed. Ha(13)

Note on the Failure of a High-Strength Brass. J. E. Newson & A Wragg (Vickers-Armstrong, Ltd.). *Institute of Metals, Advance Copy* No. 578, Sept. 1931, 9 pages.

The rapid failure of a brass rod containing 58.5% Cu, 1% Fe, 3.0% Al, 1.5% Mn, and 34.0% Zn was observed. The rod had been extruded and straightened in a two-roll reeling machine. Cracks were observed in rods that had merely been stored for several months. A study indicated that the reeling (straightening) operation had introduced tensile stresses in the interior of the rods, which caused the formation of internal cracks. A low temperature anneal removed all possibility of residual stress cracking. A similar defect could not be produced in some brasses that did not contain Al, but these latter brasses had an α plus β structure, while the Al-brass consisted entirely of β. Contains 9 references. JLG(13)

Interesting Points Developed Through Investigation of the Seams of Wood Pulp Digesters. J. P. Morrison. *Locomotive*, Vol. 38, July 1931, pages 198–205.

After a disastrous pulp digester explosion, a thorough investigation was made and the tests made to discover the causes are described in this article. The conclusions are: (1) it is found imperative to use a material of fire box quality; (2) the single strap butt-joint as well as the lap seam joint are not dependable when used in the construction of plate 1 in. and upward in thickness; in such cases, the seam should be of double butt-strap riveted construction or welded. Grooves resulting from corrosion should be most carefully watched because they weaken the material seriously. Tell-tale holes are necessary to decrease the hazard of digester operation. Ha(13)

Defects in Large Forgings. G. A. Smart. *Heat Treating & Forging* Vol. 17, Aug. 1931, pages 759–762.

The causes of piping and gas pockets, cracks in ingots, red shortness and its effects, ghost lines are explained and illustrated by photographs. The importance of eliminating these troubles is emphasized. Ha(13)

Nature of Abnormal Grain Growth in High Speed Steel. G. R. Brophy & R. H. Harrington (General Electric Co.). *American Society for Steel Treating, Preprint* No. 12, 1931, 15 pages.

Paper read and discussed before the Boston Convention of the Society in Sept. 1931. The so-called fish-scale or marble fracture in high speed steel is due to abnormal grain growth resulting from strains in the material prior to hardening. The authors present a study of the effect of strains produced thermally. The influence of small composition differences within the specimen on the heat treatment of high speed steel is discussed. WLC(13)

Causes and Avoidance of Tool Steel Failures. W. H. Wills (Ludlum Steel Co.). *Metals & Alloys*, Vol. 2, Sept. 1931, pages 112–116.

The facilities and interests of 3 groups, steel makers, tool makers and tool users, are discussed. Increasing applications for tools and their materials and demand for higher quality steel are the problems of the steel maker. Careful control by the tool maker of his conditions of heat treatment enable him to reduce his defective tools. Causes of failure due to the steel mill and due to the heat treatment are discussed. Importance of drawing is stressed. Tests such as deep etch and hardenability tests are discussed. WLC(13)

CHEMICAL ANALYSIS (14)

The Estimation of Silicon in Copper-Silicon Alloys. W. F. Pond. *Chemist-Analyst*, Vol. 20, Sept. 1931, pages 7–8.

Sawings freed from Fe by a magnet are used as a sample. 2 gm. are dissolved in 25 ml. concentrated HNO_3, 1 ml. concentrated HCl and 2 ml. concentrated H_2SO_4 added, evaporated to dryness and baked $1^1/_2$ hours. 30 ml. H_2O and 25 ml. concentrated HNO_3 are added, the solution boiled and filtered through No. 42 Whatman paper and washed with hot H_2O and hot 5% HNO_3. The precipitate is ignited slowly in platinum crucible and weighed as SiO_2. Addition of HCl reduces the volume of the siliceous mass and prevents bumping. CEM(14)

Determination of Magnetite in Copper Slags. Lathrop E. Roberts & R. L. Nugent. *United States Bureau of Mines Report of Investigations* 3120, Sept. 1931, 14 pages.

The following modifications of the Hawley method for determining magnetite in copper slags are proposed: (1) boil the sample 1 min. with the oxidizing mixture, instead of merely bringing to a boil; (2) catch the residue from the oxidation in a Caldwell crucible on an asbestos filter instead of paper; (3) dissolve the residue in Pt in a CO_2 atmosphere, rather than in glass in air; (4) titrate with titanous chloride in the cold, instead of with $SnCl_2$ in boiling solution. Magnetite can be determined with an accuracy of 2%. AHE(14)

Electrolytic Determination of Lead as Lead Dioxide. W. T. Schrenk & Philip H. Delano. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 3, Jan. 15, 1931, pages 27–29.

Best results by this method were obtained under the following conditions: time $1^1/_2$ to 2 hours, current 3 amperes, temperature 90° C. Anodes should be sand blasted and clean and the amount of Pb present between 5 and 150 mg. Solution should contain from 20 to 30% free nitric acid and about $^1/_4$ cc. sulphuric acid. Interfering elements should be absent. Effects of interfering elements were investigated and the precision of the method was determined. MEH(14)

Wavelength Tables for Spectrum Analysis. Compiled by F. Twyman & D. M. Smith. Published by Adam Hilger, Ltd., London, 1931, Second Edition. Cloth, 5½ × 8½ inches, 180 pages. Price 14s. 6d.

Various useful tables for use in chemical and metallurgical spectrography have been published since the first edition of this book was compiled, and the present time is opportune for the appearance of an up to date laboratory handbook containing all the necessary data for use in analysis by flame, arc and spark methods.

The most recent interferometric measurements of standard wavelengths have been included, and the tables of persistent lines have been revised to the I.A. scale. Tables of such lines for arc spectra (by J. W. Ryde and H. G. Jenkins), and flame spectra (by Prof. Lundegardh) are now reproduced with explanatory notes.

For those wishing to study the subject more fully from the standpoint of modern physics the section on "The Various Types of Spectrum" (by Prof. Andrade) and the complete table of ultimate lines by Dr. A. T. Williams (to which have been added spectroscopic information such as excitation potentials and temperature classification) will be of interest.

The Appendix deals with the phenomena of the condensed spark discharge and the precautions necessary for its standardization for quantitative analysis.—(14)-B-

Die Sampling Cyanide Gold Bullion at the Sons of Gwalia Gold Mine, Gwalia, Western Australia. Charles O. A. Thomas. *Australasian Institute of Mining and Metallurgy* No. 81, Mar. 30, 1931, pages 17–22.

Comparison of dip samples from the molten bullion and boring samples from 32 ingots show that in the majority of cases the borings assay higher in Au. AHE(14)

Special Problems in the Spectral Analysis of Metals. (**Specialprobleme der Spektralanalyse von Metallen.**) G. Scheibe. *Metallwirtschaft*, Vol. 10, Sept. 11, 1931, pages 723–724.

5 references. By means of spectral analysis, impurities of 0.001% or less can be determined more accurately and quickly with the use of smaller samples than by chemical means. The spectrum is produced by using 2 samples of the metal as electrodes and passing an electric arc across them or a spark of definite capacity from a condenser. For very quick results the visual method with a simple photometer and a spectroscope can be used, such as for the determination of alloys in steel. It is preferable to photograph the spectrum which takes about 30 mins. altogether. The accuracy of this method is about 2% of the element being determined. Si, B, Cr, Ni, Mo, W and V can be determined in steel, Pb in Sn and Cd, and Sb, Sn, Cd, Bi, Cu, Fe and Ni in Pb. The apparatus is the same for all elements except the spectrograph. For most determinations the ultra-violet part of the spectrum is used. CEM(14)

The Influence of Cobalt upon the Determination of Manganese by the Bismuthate Method. Takayuki Somiya. *Journal Society of Chemical Industry*, Japan, Vol. 33, July 1930, page 255B.

The author studied whether or not Mn could be determined by using the method where Mn is oxidized at room temperature by sodium bismuthate in the solution containing 20–40% (by volume) of nitric acid, if ice-cooled solution were used and the concentration of nitric acid were reduced to 1:11, 1:15, or 1:19. He found that Co was oxidized by sodium bismuthate at all temperatures and at all concentrations of nitric acid. The amounts of Co and Fe in the solution, the temperature of oxidation, the concentration of nitric acid, or the time of agitation affected the results, namely when any of these factors slightly varied, the amount of Mn found by titration was also different and the true amount could hardly be determined. MAB(14)

Contributions to Metallurgical Chemistry. (**Beträge zur Eisenhüttenchemie.**) A. Stadeler. *Stahl und Eisen*, Vol. 51, July 9, 1931, pages 889–891.

The article summarizes 11 recent publications (Jan.-Mar. 1931) on the apparatus and analysis of pig iron, steel, iron, slags, refractories, fuels, gases, oils, etc. GN(19)

Separation of Manganese from Cobalt by Ammonium Persulfate. Takayuki Somiya. *Journal Society of Chemical Industry*, Japan, Vol. 33, July 1930, pages 255B–256B.

The complete separation of Mn from Co is very important. The amount of Co that was carried down with the Mn oxides precipitated and the amount left in the filter was investigated. It was found that: (1) manganese oxides free from Co could not be precipitated with ammonium persulphate in ammoniacal or neutral solution. There was no difference in the procedures. (2) In ammoniacal solution containing considerable amounts of Zn and Co, it was difficult to precipitate Mn oxides in coarse enough form to be filtered off, and hence Mn was likely to be lost in the precipitate. It was possible to precipitate Mn completely provided the precipitation was repeated by adding ammonium persulphate and boiling until no precipitate was formed. (3) When the precipitation took place in a solution containing considerable Zn, the manganese oxides contained a very small amount of Co and could be filtered off easily. Mn might remain in the filtrate because the solution became acid due to the decomposition of ammonium persulphate. (4) In a neutral solution, the amount of Mn left in the filtrate and that of the Co carried down with the manganese oxides were much reduced by the presence of the zinc ion. MAB(14)

Determining Molybdenum in Steel. H. C. Weirick & C. H. McCollam. *Heat Treating & Forging*, Vol. 16, Sept. 1930, pages 1145–1146, 1155.

Describes in detail a method of determination of Mo in steel and iron which depends on the solubility of molybdic acid in sodium hydroxide. By means of this solubility, it is separated from the iron and is precipitated as lead molybdate from an acetic solution with lead acetate. Ha(14)

The Emission Spectrum Analysis in the Steel Industry. (**Die Emissions-Spektralanalyse in der Eisenindustrie.**) G. Scheibe. *Archiv für Eisenhüttenwesen*, Vol. 4, June 1931, pages 579–586; *Stahl und Eisen*, Vol. 51, June 18, 1931, page 775.

The paper deals with the application of small spectrometers for the qualitative analysis of Fe alloys. Within certain limits, quantitative determinations can also be made. A special method to determine Si in steel is described. An intensity method was developed for exact determinations and results of this method are given in determining Si and B. GN(14)

Investigation of Ammonium Acetate Separation of Sulfates of Lead, Barium and Calcium. Wilfred W. Scott & Samuel M. Alldredge. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 3, Jan. 15, 1931 pages 32–33.

7 references. It was found that in the ammonium acetate treatment of the sulphate precipitate, Pb may be separated from Ba, but not entirely from Ca; also that as the amount of Ba increases there seems to be an increasing difficulty in extracting all the Pb, and that less Ca is extracted in the presence of Pb and Ba than when it is the only constituent of the sulphate precipitate. MEH(14)

Fire and Chemical Analysis. Nathaniel Herz. *Engineering & Mining Journal*, Vol. 132, Oct. 12, 1931, pages 308–309.

One of the papers of a symposium on "The Homestake Enterprise." Free CN is estimated by direct titration with KI as indicator. Cyanide solutions are assayed by a modification of the Chiddey method, scorifying the Pb sponge obtained by precipitation with Zn dust and Pb-acetate. Determinations on cyanide plant solutions are: free CN, total alkalinity and reducing power. Other determinations and tests, run occasionally, include: amalgamation tests, and grading tests on sand charge and residue samples. WHB(14)

Estimation of Metals in Solution by Means of Their Spark Spectra. F Twyman & C. Stansfield Hitchen. *Proceedings Royal Society*, Vol. 133, Sept. 1931, pages 72–92.

Records experiments undertaken to extend to liquids the accuracy of quantitative analysis recently attained by the spectrography of alloys. How to produce from a solution a spectrum which shall truly represent the solution, and what effect may be expected from the presence of other metals than the one under determination, are among the questions dealt with, for they must come into consideration in applying any method of quantitative spectrography of solutions. The apparatus is shown and described in detail. At the outset of the investigation, it became apparent that the older forms of sparking apparatus, used by Hartley, Pollock and Leonard and by others were unsuited for quantitative work. It was found that, owing to incrustation of the electrodes and to decomposition of the solution around them, the spark soon became unrepresentative of the bulk of the solution. The apparatus finally devised embodies 2 principles, (1) the spark takes place from liquid to liquid; (2) there is a steady feed of fresh liquid, any scum being carried away. The experiments were divided into 2 series. The first was conducted with a view to construct curves connecting lengths of lines with percentages for metals having spectra of relatively few lines, and were accordingly made with the smaller spectrograph. The elements examined were in the form of chlorides and consisted of Cu, Zn, Bi and Pb; Co is used for the internal standard. The second series of experiments was carried out using the larger quartz spectrograph; the object was to construct similar curves for metals with complex spectra, and also to note how much such curves were influenced by the presence of definite amounts of other metals. The 2 metals selected for this series were Ni and Co; Cr was used for the internal standard. The results are tabulated as well as being shown graphically. Among the advantages of this method of chemical analysis are the following: (1) The method is rapid. (2) The accuracy as regards amounts up to 0.50% is equal to that usually obtained by ordinary methods of chemical analysis, even where the chemical separations are easy. The accuracy, moreover, unlike that of an ordinary analytical determination, where stated as a percentage of the percentage present, remains constant even when the percentage is very small. Thus, for percentages less than 0.50, the spectrographic methods could usually be substituted with advantage for the chemical ones. (3) Where difficult or complicated separations are involved, the spectrographic methods often reveal unexpected errors in the chemical analysis, or discrepancies between the findings of independent analysts and in such instances the spectrographic method would appear to be the more reliable even where the chemical results are ostensibly more precise. (4) The photographed spectrum is far superior to chemical analysis speed, certainty and completeness, for making a quantitative analysis of the metallic constituents of a complex substance. (5) The spectrogram is a permanent record of the analysis. WAT(14)

Determination of Manganese with Potassium Periodate. C. F. Miller. *Chemist-Analyst*, Vol. 20, Sept. 1931, page 8.

The sample is dissolved in 15 cc. conc. H_2SO_4, 20 cc. HNO_3 and 10 cc. H_3PO_4 and diluted to 100 cc. It is then oxidized with 0.2–0.4 g. potassium periodate, boiled and placed on steam plate 5–10 minutes. After cooling, the color is matched against standards made from $KMnO_4$ solution containing 0.1 mg./cc. CEM(14)

Tin in Tin Drosses. W. M. Muldowney. *Chemist-Analyst*, Vol. 20, Sept. 1931, pages 14–15.

A 20 g. sample is decomposed in 200 cc. H_2O and 60 cc. conc. HNO_3, diluted to 400 cc. and boiled. After standing over night, it is filtered into a 1000 cc. flask. The residue is ignited and an aliquot part fused with Na_2O_2 in an iron crucible. After leaching in water, the solution is acidified with HCl and the Sn determined as usual by titration. An aliquot part of the filtrate from the 1000 cc. flask is evaporated twice with HCl, reduced with iron wire and also titrated. CEM(14)

Arc Spectrographic Estimation of Chromium in Ruby. Jacob Papish & Wm. J. O'Leary. *Industrial & Engineering Chemistry, Analytical Edition*, Vol. 3, Jan. 15, 1931, pages 11–13.

9 references. The persistence of the arc spectral lines of Cr as conditioned by concentration of the element has been studied in the range between 5785.8 and 3120.4 A. U. The study was extended to Cr in a mixture of fused chromic oxide and alumina, and it was observed that the sensitivity of the spectral reaction was much greater in the case of Cr in fused alumina than in the case of Cr when arced as chromic acid. The method was applied to the estimation of Cr in rubies. MEH(14)

A New Method for the Colorimetric Determination of Manganese. Ralph G. Harry. *Journal Society Chemical Industry*, Vol. 50, Sept. 25, 1931, page 796.

An alcoholic solution of tetramethyldiaminodiphenylmethane when added to a solution containing manganese hydroxide in acetic acid produces a deep blue coloration which fact can be used for the quantitative determination of very small amounts of manganese. VVK(14)

Methods for Determining Manganese. Roy P. Hudson. *Heat Treating & Forging*, Vol. 16, Aug. 1930, pages 1009–1010.

Gravimetric and volumetric methods for the determination of Mn are described. Volhard's process, Crobaugh's modification, the bismuthate process, the color method and the persulphate-arsenate method are given in detail. The last named is the most rapid and the most satisfactory for determining Mn in iron and steel when it is present in ordinary percentages. Ha(14)

The "Niello" and Enamel Technique in Art-Craft. **(Die Niello- und Emailtechnik im Kunstgewerbe.)** K. Schuch. *Oberflächentechnik*, Vol. 8, Sept. 1, 1931, page 186.

An historical sketch of the very old technique of coloring of metal surfaces. Even 3000 years ago, the Egyptians used a mixture of lead sulphate, argyrose and cuprous sulphide melted together for "niellizing." The objects to be colored were covered with this mixture and then burnt. The Niello and Tula methods were developed to a high state of art particularly in India and Russia; enamelling has been highly developed in Europe since the eleventh and twelfth centuries. Some enamel compositions are described. Ha(15)

The Historical Development of Smelting and Refining Native Copper. H. D. Conant (Calumet & Hecla Consolidated Copper Co.). *Mining Congress Journal*, Vol. 17, Oct. 1931, pages 531-532.

The various steps for refining Lake copper are discussed from the year 1847, beginning of Cu mining in Lake Superior region, up to the present. Principal impurity, As, was taken care of in 1905 by intimate mixture of soda ash and lime in equal proportions; mixture was thrown over surface of furnace charge during the blowing period. This soda ash-lime mixture is now added to the charge by being blown through iron pipes into the Cu below the surface, giving more effective and intimate contact with the arsenious oxide. Application of pulverized coal has practically prevented Cu from entering slag while melting down the mineral. With a slightly reducing atmosphere in the melting down period of the furnace cycle and oxidation of metallic copper eliminated by mixing coal or coke screenings with original charge, immediate discard of slag from the reverberatory melting furnace without blast furnace treatment was made possible. Thus, blast furnace has become unnecessary. 300 ton refining furnace with Clark casting wheels pouring 50 tons (average shape)/hr. are now used. DTR(15)

Historical Sketch of the Lake Superior Copper District. James Fisher (Michigan College of Mining and Technology). *Mining Congress Journal*, Vol. 17, Oct. 1931, pages 468-471.

A concise and vivid sketch of the Lake Superior District from the beginning of operations. It is the sole place in the entire world where native Cu has been found in any considerable quantity. Only incidents and properties have been selected that typify the district. DTR(15)

The History of Malleable Iron in Liege. **(Contribution a l'histoire de la fonderie de malléable au pays de Liége.)** R. Deprez. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 863-869. 10 references.

Traces the history of malleable in Belgium from the enunciation of the basic principles by Reaumur in 1722. Lesoinne apparently began to make malleable in 1834 to 1838. Clear records date back to the establishment of Hardy and Company in 1850. HWG(15)

ECONOMIC (16)

The Future of the Copper Industry. Arthur Notman. *Canadian Mining & Metallurgical Bulletin* No. 229, May 1931, pages 629-637.

An economic study. AHE(16)

The Metal Year 1930. **(Das Metalljahr 1930.)** Alfred Marcus. *Metallbörse*, Vol. 21, Jan. 31, 1931, pages 199-202.

The aluminum market was also affected by the business depression during the past year as evidenced in a noticeable decrease in world consumption. It was found during the past year that the increase in aluminum sales due to high copper prices is relatively small and that, on the contrary, the reduction in the price of copper did not cause a decrease in aluminum sales. During the past year, the European cartel decreased the price of aluminum £10 per ton. In Germany, the old import regulations were revised and a tariff of 25 RM. per kilogram was imposed. In Switzerland, the tariff on crude aluminum was increased from 5 to 65 Swiss francs per kilo and the tariff on rolled products was increased 60 francs, that is, making them practically prohibitive. German aluminum imports for 1930 decreased considerably over the previous year although it is difficult to determine whether it was entirely the result of the tariff or the bad business conditions. Nevertheless, the imports of crude aluminum for 1930 were 4368 tons with an export of 4903 tons, that is, the exports were a few hundred tons greater than the imports, whereas in the preceding year the imports exceeded the exports by about 3600 tons. 70% of the aluminum imports during 1930 came from Switzerland. Recently, however, German-Swiss aluminum relations have become somewhat strained. America has continued to be a strong competitor in Asia. The Americans have lowered their domestic price of aluminum since their tariff has been reduced, as has the European cartel. It would seem that the "American danger" is not as great as it has been pictured in the German and Swiss tariff debates. The decrease in production has not been one-sided. American competition did not prevent the German exports of rolled products to British India from increasing from 649 tons in 1929 to 937 tons in 1930. The exports of manufactured goods to England increased from 564 tons to 795 tons. In many other places there has been a decrease, but the total for 1930 is 4696 tons as against 4426 tons for the previous year. The exports of aluminum ware have decreased considerably from 6975 tons to 3933 tons. The exports of foil increased somewhat, namely, from 3322 to 3547 tons. China with 926 tons (as against 619 tons for 1929) was the largest customer. The imports of foil to Anglo-Saxon countries have decreased. WHB(16)

The Beryllium Problem. **(Il problema del Berillio.)** G. Panebianco. *Metalli Leggeri*, Vol. 1, May-June 1931, pages 9-11.

The beryllium problem is not primarily metallurgical, since its metallurgy does not present special difficulties, but rather one of extraction from the ore. Unless it is possible economically to utilize deposits very low in Be, the price of the metal will probably remain high. Low-Be deposits may easily exist in which the presence of Be is not known because its presence is difficult to detect analytically in the presence of Al. The absence of Be from some clays derived from Be-bearing rocks indicates that there has been a leaching in nature. This suggests the possibility of a "permutation" or base-exchange as a concentration method from silicates carrying Be. This suggestion is made by analogy and not on the basis of direct research. Be has not been studied from the point of view of light alloys, but should be. HWG(16)

The Economic Utilization of British Pig-Iron Resources. C. H. Ridsdale & N. D. Ridsdale. *Foundry Trade Journal*, Vol. 42, June 19, 1930, pages 453-454; Vol. 43, July 3, 1930, pages 7-10; July 10, 1930, pages 28-30; July 17, 1930, pages 46-47; July 24, 1930, pages 64-65; July 31, 1930, pages 82-83; Aug. 14, 1930, pages 114-116; Aug. 21, 1930, pages 129-130, 133-134; Aug. 28, 1930, pages 150-152; Sept. 4, 1930, pages 168, 170.

Paper read before the annual convention of the Institute of British Foundrymen. Includes discussion. Gives information of British pig iron resources that will enable a foundryman to select varied brands of iron for his own particular purpose as near to his own locality as possible. Data collected by circular letter to all makers of pig iron in the country asking for the latest information. Inherent properties of pig iron are given. In calculating mixtures, the method which seems to be the most reasonable is to base the quantity of metal charged per round upon the weight per ring layer of fusion coke charged. Includes tables giving composition of the district irons and names of firms handling them. VSP(16)

Economic Significance of Specifications from the Standpoint of a Us er o Steel. P. Parke (Pullman Company). *Preprint, Symposium on Economic Significance of Specifications for Materials, Proceedings, American Society for Testing Materials*, 1931, pages 11-14.

Discusses advantages of specifications in insuring uniformity, sound economic use of different grades of material, and opening up a field of fair competition. HWG(16)

The Copper Industry. Robert E. Tally (United Verde Copper Co.). *Mining Congress Journal*, Vol. 17, Oct. 1931, pages 463-466.

Excellent discussion of present economic condition of the copper industry. Major requirements for stabilizing Cu are: (1) genuine co-operation among producers of the world in reduction and maintenance of stocks at a normal basis; (2) revision of the anti-trust laws to an extent that collective curtailment, which is the only effective means for the adjustment of supply to demand, is not only permissible, but encouraged; (3) more intensive efforts toward new uses for the metal, in alloy with steel and other metals, by research; (4) marketing methods that will prevent drastic price fluctuations by the sale or purchase of small amounts of Cu; (5) orderly liquidation of excess inventories; (6) sales limited to maximum delivery of 90 days, and by agents financially interested in maintaining prices, and not by dealers and speculators; (7) consolidation of mines into large groups for the reduction of selling and other overhead expenses, and for the acquisition of refining facilities which the individual producer cannot afford; (8) cost reductions through improved metallurgical methods, and the recovery and marketing of by-products; (9) co-operation between producers and consumers, with publication of frank interchange of inventory data. The future of the industry will depend upon the character and extent of co-operation among producers and the sympathy and co-operation of the Government. DTR(16)

The Utilization of Waste Material in the Cast Iron Foundry. **(L'emploie des déchets divers en fonderie de fonte.)** E. K. Smith & F. B. Riggan. *Revue de Fonderie Moderne*, Vol. 25, July 10, 1931, pages 242-243.

The methods noted in this article as suitable for American conditions (*Iron Age*, Apr. 30, 1930) can equally well be applied to French conditions. Ha(16)

Antimony in 1930. Paul M. Tyler. *United States Bureau of Mines, Mineral Resources of the United States*, 1930, Part I, Sept. 8, 1931, pages 1-15.

Domestic consumption of Sb dropped more than $^1/_3$ in 1930. Imports for consumption were, in short tons: Ore (contained Sb), 863; liquated SbS, 713; metal, 7700; oxide, 690. From domestic and foreign ore, 13,711 tons of antimonial lead was produced containing 1685 tons of Sb. Recovery of secondary Sb was 8082 tons. AHE(16)

Gold, Silver, Copper, Lead and Zinc in Arizona in 1929. C. N. Gerry & T. H. Miller. *United States Bureau of Mines, Mineral Resources of the United States*, 1929, Part 1, July 30, 1931, pages 765-829.

In 1929, Arizona produced $155,567,133 worth of Au, Ag, Cu, Pb, Zn, the largest production since the war and the largest production of the 5 metals for any state. Cu represented nearly 94% of the total. Au production (202,318.14 oz.) increased more than 5%; Ag output (7,543,283 oz.) increased 11%, but only 1% in value; Cu increased about 13% in quantity (to 830,628,411 lbs.) and almost 39% in value; Pb production (16,054,122 lbs.) increased about 12% in quantity and 21% in value; Zn output (2,458,580 lbs.) was 92% over 1928 in quantity and 108% in value. AHE(16)

PLANTS & LABORATORIES (17)

Ore Crushing and Sinter Plant of the Neunkircher Plant at Neunkirchen (Saar). **(Erzbrech- und Sinteranlage des Neunkirchen Eisenwerks, A. G., vorm. Geb. Stumm in Neunkirchen (Saar).)** J. Oppenheuser. *Stahl und Eisen*, Vol. 51, Sept. 17, 1931, pages 1165-1167.

This plant is equipped with top crushers of a capacity of 500 tons minette/hr., a Dwight Lloyd sintering band with a capacity of 38-46 tons/hr. The band has a width of 2 m. and a suction surface of 40 m.^{2} Figures on the power consumption of the plant are given. GN(17)

The Fabricating Shop Nord of the Neunkircher Iron Work. **(Die Zurichterei Nord des Neunkircher Eisenwerkes.)** O. Vogel. *Stahl und Eisen*, Vol. 51, Aug. 27, 1931, pages 1081-1085.

Illustrated description of the fabricating shop after its modernization. GN(17)

The Present Experimental and Testing Bureau of the German Acetylene Society in Berlin-Friedenau. **(Die jetzige Untersuchungs- und Prüfstelle des deutschen Azetylenvereins in Berlin-Friednau.)** E. Sauerbrei. *Autogene Metallbearbeitung*, Vol. 24, Sept. 15, 1931, pages 281-283.

The new bureau contains, among other rooms, a test room of about 100 m.^{2} for testing acetylene apparatus, 3 sets of Caro apparatus for carbide analysis, flow-meters for quantities of 50-50,000 liters/hr., water manometers up to 2000, mercury manometers up to 20,000 mm. water. A general description is given. Ha(17)

Forging in a Tool and Alloy Steel Plant. E. J. Poole, Jr. *Heat Treating & Forging*, Vol. 17, Mar. 1931, pages 246-249.

The layout of a forge, dimensioning of foundations for the anvil, avoidance of vibrations, construction of cylinders for steam hammers, selection of hammers and necessary operating crew are fully discussed. Ha(17)

The Quantity Production of Light Gauge Drums. E. B. Peet & W. P. Blake. *Metal Stampings*, Vol. 4, Mar. 1931, pages 207-212, 220.

Authors describe new process and production line of automatic machinery recently developed for the manufacture of corrugated, light gage, sheet steel drums at rate of 3600/10 hr. day. Also give diagrams of drum design, lock seams and end seam employed, and plan of factory layout with photographs of various machine units. JN(17)

The Laboratories of the Ore Dressing and Metallurgical Division, Mines Branch, Department of Mines, Ottawa. C. S. Parsons. *Canadian Mining & Metallurgical Bulletin* No. 233, Sept. 1931, pages 1033-1038.

Descriptive, with examples of recent results. AHE(17)

Heat Treated Pipe Couplings Solve Long Distance Gas Transportation. C. B. Phillips. *American Gas Journal*, Vol. 134, Jan. 1931, pages 56-57.

Natural gas furnaces are installed; the furnace dimensions are given; an automatic temperature control is used. The layout makes use of gravity. MAB(17)

New Heat Treatment Shop at Bethlehem. S. D. Gladding. *Heat Treating & Forging*, Vol. 16, Dec. 1930, pages 1523-1526, 1529.

The installation of electric resistance furnaces, quenching arrangements, automatic temperature control and testing equipment is fully described. Ha(17)

A Forge Plant in the Chicago Area. M. R. Chase. *Heat Treating & Forging*, Vol. 16, Sept. 1930, pages 1152-1155.

Forging equipment and practice at the plant of A. Finkl & Sons Co., Chicago, are described. Ha(17)

MACHINERY & SUPPLIES (18)

Machine Tools from the Manufacturing User's Point of View. HERBERT C. ARMITAGE. *Transactions Manchester Association Engineers*, 1929–1930, pages 265–326.

Includes discussion. The costs of production of certain components by old and by up-to-date machines are analyzed and compared and production costs generally are discussed. Among various modern machines described in detail are center lathes and the multiple type of cutting tool; drilling, milling, gear-cutting, and grinding machines; checking capstans and turret lathes, chucking automatics and electric welding machines. It is anticipated that the new cutting materials will cause small changes in machine-tool design, but the effect will be less than caused by the introduction of high-speed steel. The tendency is now toward standardized single-purpose machines; multiple-purpose machines will probably become obsolete. Tables are given showing the advantages and disadvantages of the 2 types of machine and of individual motor drive. Ha(18)

Commercial Types of Power Presses. Slide Motions Employed in Power Presses. E. V. CRANE. *Metal Stampings*, Vol. 4, Feb. 1931, pages 131–134; Mar. 1931, pages 239–242.

The reciprocating slide or ram of the average punch press is most commonly actuated by a crank which describes smooth harmonic motion. Cam actions are employed to a lesser extent for obtaining bottom dwells or for operating knockouts. Bottom dwells are also obtained by the use of a special Geneva action, which stops the press at bottom center under full load. The same stop mechanism is used in extrusion presses to remove impact shock. This greatly reduces tool breakage. Knuckle joint presses describe motion curves resembling crank motion, except for a definite flattening out at the bottom of the stroke to produce a semi-dwell. Extremely high pressures are exerted by the ram at the bottom of the stroke, resulting in a proportionately high load carrying capacity. The short working range of these presses limits their use to processes of coining, embossing, swaging, sizing and special cases of extrusion. The power screw press or percussion press, although much slower in action, resembles the drop hammer in that the work absorbs the entire energy of the slide. In the flat edge trimming press, 3 cam actions are combined for trimming square all 4 sides of a drawn shell in sequence. Cam stripper perforating presses combine an auxiliary cam motion with a crank motion. The cam actuated stripper clamps the metal positively while the crank actuated slide carrying a number of perforating punches operates to pierce the strip. JN(18)

Overhead Conveying Machinery in Steel Mills. E. T. BENNINGTON (Cleveland Crane & Eng'r'g. Co.). *Rolling Mill Journal*, Vol. 5, Feb. 1931, pages 111–114.

The use of overhead conveying machinery has expanded considerably in recent years, with resultant savings in factory space, maintenance and material handling costs. Demands for greater speeds and increased flexibility have led to the development of various special rolled shapes for rails. Materials for rails must resist wear and peening action. A specialized rail, high in C and Mn content, designed with a raised section or wearing tread, shows no sign of material wear from carrier wheels operating at 600 ft./min. The development of specialized monorail systems with electric hoists has progressed rapidly. The author illustrates the use of conveying machinery in a wire mill and in strip, sheet and tube mills. JN(18)

Vibration-Free Shaking Molding Machine with Compressing for Compressed Air Operation. (Stossfreie Rüttelformmaschine mit Pressvorrichtung für Druckluftbetrieb.) WEIL. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, July 17, 1931, pages 581–582.

Description and illustration of the machine which is operated entirely mechanically for the filling up with sand. It is built for a maximum pressure of 16,000 kg. with 8 atmospheres air pressure. Ha(18)

Rapid Acting Scrap Piling Press. (Schnell arbeitende Druckwasser-Schrottpaketierpresse.) E. SCHWENZNER. *Stahl und Eisen*, Vol. 51, Apr. 16, 1931, page 501.

Illustrated description of a new scrap press built by Demag, Duisburg. GN(18)

Reel with Automatic Switching of the Electric Driving Motor. (Drahthaspel mit selbsttätiger Schaltung des elektrischen Antriebes.) H. SCHMITT. *Stahl und Eisen*, Vol. 51, Apr. 9, 1931, pages 465–466.

A new reel for reeling rods and other small shapes which shows an entirely automatic control and offers many advantages in comparison with all previous constructions is described. GN(18)

Foundry Crane with Pig Molding Machine. (Giesshallenkran mit Masselformmaschine.) W. ROLLENHAGEN. *Stahl und Eisen*, Vol. 51, July 23, 1931, pages 936–938.

Report 121 of the Blast Furnace Committee of the Verein deutscher Eisenhüttenleute. The paper describes a new type of crane construction. The crane is equipped with a pig molding machine and all the other accessories in order to facilitate the handling of the cast pigs. The crane, as installed at the Norddeutschen Hütte in Bremen-Oslebshausen, can handle a production of 800–850 tons of pig iron per day. GN(18)

Experimental Investigations of a Screen Washer for the Primary Cleaning of Blast-Furnace Gas. (Recherches expérimentales sur un laveur à claies pour l'epuration primaire des gaz de hautsfourneaux.) MARCEL STEFFES & ROB. WELTER. *Revue Technique Luxembourgeoise*, Vol. 23, July-Aug. 1931, pages 145–149.

Screen washers are stationary gas cleaners with the double purpose of precipitating the dust and cooling the gas. An installation is described which treats 50,000 m.^{3}/hr. Tests show the influence of different quantities of water (100, 200, 300 m.^{3}/hr.) on the cleaning effect. The amount of gas was varied at the same time from 20,000 to 60,000 m.^{3}/hr. The conclusion is that the choice of the water ratio is determined by the cleaning effect rather than by thermal considerations. The series of tests are illustrated in curves and tables. Ha(18)

The Design and Application of Cranes to Steel Mill Service. Part 1. G. W. YANNEY (The Alliance Machine Co.). *Rolling Mill Journal*, Vol. 5, Jan. 1931, pages 53–54.

Introductory article. Gives extensive list of the types, capacities and functions of the great variety of electric cranes employed in the blast furnace, open hearth and mill departments of the modern steel plant. JN(18)

Index to Iron and Steel Patents—1930-1931, Supplement. V. E. KINSEY & T. E. HOPKINS. American Compilation Co., Pittsburgh, 1931. Paper, 6 × 9 inches, 12 pages. Price $2.00.

Abstracts of U. S. ferrous metallurgical patents—Class 75 sub-classes 1, 14, 27, 44, 45, 46, 47, 48, 49, 50, 51, 65, 77 & 197.

Includes patentee, constituent, assignee and classification indexes.

The application date has been added to each abstract, this being the only change from the original volume.—M. L. Moorman (19)-B-

MISCELLANEOUS (20)

Reducing Torsional Vibration by Damping Devices. J. ORMONDROYD. *Machine Design*, Vol. 3, July 1931, pages 33–36.

For variable speed engines, devices must be used either to keep the vibration amplitudes of torsional vibration within small values or to place the critical speeds in regions where operation is possible but not probable. Several devices used for the purpose of eliminating these vibrations are described. Usually, ordinary (Coulomb) friction or viscous friction is used to dissipate vibration energy. The theory of the dampers is briefly given and a few constructions are described. Ha(20)

The "Dinta" System. A. MARSON. *Foundry Trade Journal*, Vol. 45, Sept. 10, 1931, pages 167–168.

An article explaining the system of industrial training of youth, now adopted by all important plants in Germany. It is stated to have been "created by industry to stop subsidies from public funds being used in industry." The 10,000 boys enrolled under it are given vocational, physical and technical training, as well as opportunities for character development. The system has also been extended to include aged and clerical workers. Its trend is toward the making of man into "the machine master, and not a machine slave." OWE(20)

Surface Hardness of Gear Teeth. A. C. RASMUSSEN. *American Machinist*, Vol. 74, June 11, 1931, pages 907–908.

The Hertz formula for determining the maximum compressive stress produced at the point of contact of 2 gear teeth under load is modified so as to take into account also the surface hardness of the tooth which governs the permissible load. Ha(20)

Lubrication and Oiliness. A. P. SACHS. *Houghton's Black & White*, Vol. 3, Apr. 1931, pages 4–8.

It is maintained that, although the quality of a lubricant can be determined in a laboratory test, its value for any given service can be ascertained only by a performance test. General specifications, therefore, can only be given for qualities covering a certain range of uses. Ha(20)

Detonation Temperatures of Acetylene. (Verpuffungstemperaturen des Azetylens.) W. RIMARSKI & M. KONSCHAK. *Autogene Metallbearbeitung*, Vol. 23, July 1, 1930, pages 211–215.

Pure acetylene explodes in the presence of an iron plate heated to 510° C. and a minimum pressure of 3.05 atmospheres and at a flow velocity of 0.4 l./mm. See *Metals & Alloys*, Vol. 2, Oct. 1931, page 228. Ha(20)

Railroad Saves Six Times Electric Heat Cost. WIRT S. SCOTT (Westinghouse Elec. & Mfg. Co.). *Electrical World*, Vol. 98, Sept. 5, 1931, pages 423–427.

Extensive savings have been effected in the babbitting of bearings, armature and coil baking, and annealing steel castings by the Norfork & Western Railway at their Roanoke, Va. shops. Much greater exactness of heat treatment is secured, longer life of the treated parts, labor saved, etc. WHB(20)

Utilization of Scrap for New Products by Means of Welding. (Verwendung von Materialabfällen zur Neuanfertigung mit Hilfe der Schweisstechnik.) F. WECKWERTH. *Schmelzschweissung*, Vol. 10, July 1931, pages 184–186.

The manner in which scrap parts can be used again to great advantage in building up small parts, fittings, etc., by welding instead of remelting them in the furnace is demonstrated and advocated. Several examples are illustrated. Ha(20)

Salt Cellars—Old and New. Part I. Salts from 15th to 18th Century. A. FREDERIC SAUNDERS. *Metal Industry*, N. Y., Vol. 29, Aug. 1931, pages 331–332.

Examples and descriptions of the characteristics in design of old salt cellars are given. PRK(20)

Thermocouples Whose Elements Are Longitudinally and Transversely Magnetized Ferromagnetic Substances. STEWART SEASS. *Physical Review*, Vol. 38, Sept. 15, 1931, pages 1254–1257.

A ferromagnetic wire is bent at right angles to form a square U-shaped conductor. If the 2 bent ends are kept at different temperatures and the section between the 2 corners is magnetized transversely while the portions leading from the right angles are longitudinally magnetized, an e. m. f. is set up between the bends. Values for this e. m. f. for different magnetic fields are shown. Also, the relation between this effect, discovered by Sir William Thomson in 1856, and an effect discovered by von Ettingshausen and Nernst, nearly 30 years later, are indicated. WAT(20)

Internal Stresses. (Ueber innere Spannungen.) OTTO MIES. *Schmelzschweissung*, Vol. 10, Sept. 1931, pages 213–215.

The author shows that internal stresses are present in almost any technical construction and he investigates how great they are and what direction they assume. In general, the stresses occurring in modern welded constructions can be assumed not to be greater than in the types of joining materials formerly used; that is, they are usually not unduly high. Ha(20)

The Influence of Electromagnetic Waves on the Resistivity and Hardness of Metals and Alloys. (Influence des ondes électromagnétiques sur la résistivité et la dureté des métaux et alliages.) G. MAHOUX. *Comptes Rendus*, Vol. 193, July 6, 1931, pages 27–29.

Two bars of the same material—the one submitted to the direct action of an electromagnetic field, the second supported at a distance of 10 cm. from the first—were found by the author to undergo a decrease in electrical resistivity with time. After 2 hours treatment in the field, a sharp drop (followed by a recovery) of resistivity was observed. The resistivity, however, did not return to its initial value. This phenomenon was found to recur every 2 hrs. Two steels, a cast Fe, and a complex Al alloy were investigated. The bars were first polished; after having been subjected to the action of the electromagnetic field for 2 hrs., successive dark and light rings appeared on the bars, these serving to indicate the existence of nodes and loops in the bars. At the conclusion of the experiments, hardness tests on one of the steel bars showed that the hardness had increased during the experiment from 429 (Brinell) to 444 and 447, respectively, the high and low values corresponding to the nodes and loops which had been revealed by the coloring of the bar during the test. A similar phenomenon was noted in the case of the Al-alloy bars. OWE(20)

Rubber Stamp Method of Etching Metals. CHARLES H. PROCTOR. *Metals Cleaning & Finishing*, Vol. 2, Dec. 1930, pages 1069–1072.

Rubber stamp method is simplest of all used for etching metals. It gives poorest results and only certain classes of work can be etched by it. It is used very extensively for etching of steel knives. Procedure consists of coating the metal with a varnish made by dissolving gum-guaiacum in alcohol. The knives should be slightly warm. Rubber stamp is pressed down upon a piece of cotton cloth, saturated with a strong solution of KOH. The stamp is then stamped on the varnish. After the KOH is allowed to remain on the surface for about a minute, it is washed off, removing the varnish touched by it, at the same time. Etching is done by dilute HNO_3. The acid is rinsed off after etching, and the varnish is removed by treating with hot alkali. MS(20)

Statistical Control, How New Science Promotes Uniformity of Product. ANSON HAYES & R. T. PASSANO (Research Laboratories, American Rolling Mill Co.). *Metal Progress*, Vol. 20, Sept. 1931, pages 94–98.

The authors present a discussion of the use of statistical methods in attaining control of manufacturing processes. WLC(20)

On the Electric Resistance of Carbon. Z. NISHIYAMA. *Kinzoku no Kenkyu*, Japan, Aug. 1931, pages 403–415.

The experiment was carried out to explain an abnormal electric property of C which belongs to such semi-conductors as C, B, Si, Ti, Ge and Zr. With pure graphite filaments which were prepared by the deposition of C decomposed from carbon tetrachloride and treated at such high temperatures as 2500° and 3000° C., the electric resistance was measured at temperatures from 0° C. to 2000° C.; the grain size was also examined by X-rays. It was found that the grain size of the graphite was larger when it was heated at high temperatures. When the grain was very fine, the electrical resistance was far greater than that of metals, just as in the case of semi-conductors. When heated, its electrical resistance decreases first and, thereafter, it begins to increase. If the graphite was heated to 3000° C. for one hour, the electrical resistance and its thermal coefficient are nearly the same as that of metals. Thus it was concluded that C has originally the same electrical property as metals, but that the fineness of the grain causes an apparent anomaly of electrical resistance. KT(20)

The Phenomenon of Slip in Plastic Materials. A. NADAI (Westinghouse Elec. & Mfg. Co.). *Preprint, Proceedings American Society for Testing Materials*, Vol. 31, Part 2, 1931, 36 pages.

Edgar Marburg lecture before the A. S. T. M. The laws of deformation due to slip in plastic materials are traced through the behavior of heaps of sand, of iron filings in a magnetic field, through Lüders' lines in mild steel, slip lines in paraffin tested in compression and geological strata deformed by pressure. The mathematical laws governing slip are discussed at some length. HWG(20)

Recovery of Metals from Waste Materials. J. W. HINCHLEY. *Institution of Chemical Engineers, Advance Copy*, Dec. 1930, pages 59–66; abstracted in *Engineering*, Vol. 131, Jan. 2, 1931, page 26.

The author refers to the general importance of recovery and conservation of metals and then gives the detailed working out of 2 recovery processes. Those considered are the detinning of tin plate scrap by an alkaline plumbate solution and the recovery of Zn and Pb by a wet extraction process, from dumps, accumulated at works using the old English method of Zn smelting. LFM(20)

Producing 90-Degree Rounded Corners. J. L. ANDERSON. *Sheet Metal Worker*, Vol. 22, Oct. 16, 1931, pages 598–599.

Explanation of the laying out on the sheet metal for rounded corners to be welded. Ha(20)

Magnetism and the Quantum Theory. H. S. ALLEN. *Proceedings Physical Society*, London, Vol. 42, 1930, pages 372–378.

The results of the modern form of the quantum theory are reviewed in relation to the explanation which they afford of magnetic phenomena. Reference is made to the magnetic moment of the spinning electron, which appears to play an important part in the new quantum mechanics, and to the explanation of the molecular field of Weiss as originating in the quantum interaction between electrons. The necessity for taking into account the principle of relativity is emphasized in connection with the possible structure of the electromagnetic field: the quantum theory may demand 4-dimensional tubes of force in space-time. Heisenberg's principle of indeterminacy is briefly discussed. Ha(20)

National Machine Tool Builders' and Dealers' Association. C. A. HERBERTS. *Western Machinery World*, Vol. 22, Sept. 1931, pages 387–388.

The feasibility of a national association of machine tool builders and tool dealers is forcibly brought out by the author, president of the Los Angeles Machinery Dealers Association. Such constructive ideas should lead to closer coöperation, to the ultimate increase of new machinery sales throughout the country, to normal production of our master tools of industry and finally to the decrease of unemployment in the machine tool industry. WAT(20)

Electricity in the Manufacture of Steel. A. N. DIEHL. *Electric Light & Power*, Vol. 9, June 1931, pages 34–39.

A review of the uses in the whole field of steel making in drives, auxiliaries, transportation and supervision of operations. As the total electric energy required per ton of steel from coal and ore to finished product, the following figures are given for each case, exclusive of energy required for mining transportation: ingot, 30 kwh.; billets, 103 kwh.; structural material, 117 kwh.; plates, 126 kwh. A few installations are illustrated. Ha(20)

On Molecular and Atom Volumes 33. Volumes and Models of Atoms. (Ueber Molekular- und Atomvolumina 33. Atomvolumina und Atommodelle.) W. BILTZ (University of Göttingen). *Zeitschrift für physikalische Chemie*, Bodenstein Festband 1931, pages 198–210.

The 33rd communication on the subject presents substantiation for the "Steren Rule" established by the author a year ago. ("Stere" means the quotient between the volumes and the principal quantum numbers of the outermost shell). For more than one half of all elements, the following formula of approximation holds true; $v_0 = \frac{11.3\, n}{N}$, wherein v_0 = zero point atom volume, n = quantum numbers of the outermost shell, N = group number of the element in the periodic system. There is no denying that a relationship exists between the atomic-physical date of isolated atoms and the space occupied by the multiplicity of such mass particles. Divergencies are ascribed to a large variety of inter-atomic and inter-molecular forces. The data computed for the various elements—including metals—are graphically presented and collected in tables. EF(20)

The Prevention of Smoke in Metallurgical Operations. C. H. DESCH. Paper before the *Third International Conference on Bituminous Coal* in Pittsburgh, Pa.

While, in most manufacturing plants and power stations, smoke emission is avoidable and, from a public health point of view, has been suppressed by modern methods and regulations, it is maintained that certain metallurgical operations are accompanied by smoke emission which cannot be dispensed with without injury to the quality of the product; as, for instance, in the Bessemer process, but especially in heating of steel by the burning of coal to create a protective atmosphere. This question is thoroughly discussed. Other fuels cannot, apparently, give the same degree of protection of the same kind of atmosphere. The author advocates further study of this question to determine, over a sufficiently wide range of temperatures, the limits of composition within which a mixture of given gases will remain neutral towards a given steel. Metallurgists and fuel experts must cooperate. Ha(20)

Lubrication of Modern Conveyor Mechanisms. *Canadian Foundryman*, Vol. 22, July 1931, pages, 12–14.

A discussion of the principles underlying the operation of antifriction (ball or roller) as compared with plain- or sleeve-type, bearings with special reference to the characteristics which must be looked for in oils and greases for use in this connection. OWE(20)

Bearing Lubrication, Oil Film Pressure. *Lubrication*, Vol. 7, May–June 1931, pages 49–60.

Apparatus is described for studying the oil film pressure within a complete journal bearing, lubricated from one end, with respect to pressure distribution, friction coefficient, journal running position at known intensities of load, journal speed and dimensions. The test results show that the pressure distribution within the oil film differed widely from the usually accepted uniform distribution. Ha(20)

The Bending of a Thin Circular Plate. J. J. VINCENT. *London, Edinburgh and Dublin Philosophical Magazine and Journal of Science*, Series 7, Vol. 12, July 1931, pages 185–196.

A theoretical investigation of the behavior of the plate when it is supported with its rim at the same level everywhere and when the circumference of the plate is held fixed so that the radial strain is zero at the circumference. Ha(20)

Stresses Due to a Small Elliptic Hole or a Crack on the Neutral Axis of a Deep Beam under Constant Bending Moment. BIBHUTIBHUSAN SEN. *London, Edinburgh and Dublin Philosophical Magazine and Journal of Science*, Series 7, Vol. 12, Aug. 1931, pages 312–319.

A theoretical investigation developing formulas for the magnitude and location of the stresses. Ha(20)

Trends in the Junior Metal and Mineral Industries, 1930. GUY C. RIDDELL & D. M. LIDDELL. *Mining & Metallurgy*, Vol. 12, Jan. 1931, pages 41–46.

Brief review of the atomic physics, television, Ra, He, corrosion-resistant alloys, uses of Mg, light metals, Be, Ti, Zr and Hf, U metal, Tl alloys, Ce glass and dry ice. Ha(20)

Manganese in Water—Its Occurrence and Removal. R. SPURR WESTON. *Water Works & Sewerage*, Vol. 78, July 1931, pages 196–198.

Although Mn is usually present in water in only minute amounts; a few cases are reported where Mn occurred in such quantities that it interfered seriously with the ortho-tolidine test for Cl. The possibilities of occurrence of Mn are discussed and the ways for its elimination are described. Ha(20)

Lead Oleate Lubricants for Heavily Loaded Gears and Bearings. MAURICE RESWICK (Pennsylvania Lubricating Co.). *Iron Age*, Vol. 128, Sept. 24, 1931, pages 816–819.

The second of a series of articles. Lead oleate is a broader line lubricant for critical conditions of pressure and speeds. It will maintain a lubricating film beyond the breakdown point of straight mineral oil. Made up of low cold test oils, lead oleate can be used without danger of channelling or congealing at low temperatures. Using lead oleate lubricant, it should not come in contact with H_2O. Great care should be exercised in adopting lead oleate in the industrial field. Heavy viscosity lead oleate is used in the automobile and industrial fields. Extra viscosity lubricants are used in the steel industry. VSP(20)

Tolerance and Hardness of Precision Gage Blocks. Correspondence from J. ZUBKO & C. J. POND. *Metal Progress*, Vol. 19, June 1931, pages 86–87.

LABORATORY APPARATUS (21)

Laboratory Furnaces and Temperature Regulators. (Fours de laboratoire et régulateurs de température.) PIERRE CHEVENARD. *Revue de Métallurgie*, Vol. 28, Aug. 1931, pages 453–468.

The temperatures available in a resistance laboratory furnace are not uniform. They depend on the manner of winding, position of the furnace type of the winding material and the influence of bars extending from the furnace during heating. The best solution for obtaining a uniform temperature lies in the use of 3 independent windings shunted to the supply of current. An example of the importance of the accurate temperature control is given in case of dilation curves obtained on drawing of several quenched steels. Two temperature control devices are described in detail, one based on the expansion of a bar inserted in the furnace; the other on the increase of length of a wire heated by a current connected through a shunt with the line feeding the heating coils. JDG(21)

Alternating Immersion Test. (Wechselbad zur Materialprüfung.) R. HEILBRUNN. *Zeitschrift für Instrumentenkunde*, Vol. 50, Oct. 1930, pages 590–591.

A simple device is described for submitting materials to alternating immersion tests in 2 different baths by a reversible clock mechanism. EF(21)

Microscopes. WILLIAM L. PATTERSON (Bausch & Lomb Optical Co.) *Metal Progress*, Vol. 18, Nov. 1930, pages 56–57.

The author describes advances in the construction of metallographic microscopes. WLC(21)

Laboratory Furnaces for High Temperature Work. N. RYLAND DAVIS & C. SYKES. *Journal Society Chemical Industry*, Vol. 50, June 19, 1931, pages 506–514.

The author describes types of small induction and resistance furnaces now available for temperatures up to 1600° C. 9 references. VVK(21)

A Laboratory Furnace for Testing Resistance of Firebrick to Slag Erosion. RALPH K. HURSH & CHESTER E. GRIGSBY. *University of Illinois Engineering Experiment Station Circular* No. 17, Oct. 1928, 18 pages.

A cylindrical furnace chamber is supported vertically on rollers and is rotated about its axis during the test. It is heated to any desired temperature with controlled atmospheric conditions by a blast burner using city gas and air, both at high pressure. Powdered slag is fed at a uniform rate through the burner and impinges with the blast on the vertical faces of the standard-sized test bricks which form the lining of the chamber. The melted slag flows down over the faces of the bricks and out through a port in the middle of the furnace bottom. By rotating the furnace, each test brick is brought successively and repeatedly into position before the burner. Identical temperature conditions and uniform slag treatment for the several bricks is thus insured. A sufficient number of samples can be tested at one time in this manner to give comparable results. 5 brands of commercial bricks were tested; the results are presented in tabular form. WAT(21)

An Electrical Nickel Furnace for Metallurgical Investigations. (Ein Nickelofen für metallurgische Untersuchungen.) H. V. STEINWEHR & A. SCHULZE (Physikalisch-Technische Reichsanstalt). *Zeitschrift für Instrumentenkunde*, Vol. 50, Mar. 1930, pages 194–197.

Advantages claimed: uniform temperature over a certain length of the furnace, attaining of the temperature desired in a very short time, no fluctuations in temperature. Utilization suggested: determinations of thermal expansion, transition points, etc. Consists of Ni-block with holes drilled into it. Nichrome resistance wire. Cooling-off speed can be regulated by blowing air through the solid Ni-block. Long time tests up to 800° C. Short tests up to 1000° C. Table with temperature gradient at various temperatures is included. EF(21)

Equipment to Draw Heating and Quenching Curves. Correspondence from K. HONDA, Sendai, Japan. *Metal Progress*, Vol. 19, Jan. 1931, pages 87–88.

The writer describes a self-recording dilatometer for studying rapid temperature changes. Photograph shows the apparatus and a typical curve. WLC(21)

Recording the Melting Process and the Properties of the Cast Material. (Het registreezen van het smeltproces en de eigenschappen van het gegoten materiaal.) A. THOMASSEN. *De Gieterij*, Vol. 4, Nov. 1930, pages 180–184.
It is desirable to have complete daily reports on foundry practice together with chemical and physical data on the successive castings. A number of foundries might establish a central laboratory for complete physical and chemical testing. Using the same data sheets the various plant superintendents might profitably discuss the results obtained at stated intervals of time. HSvK(22)

Difficulties in Casting and Their Elimination in the Application of Low-Carbon Cast Iron for Medium-Heavy and Light Machine Casting. (Ueber Giessschwierigkeiten und deren Beseitigung bei der Verarbeitung von niedriggekohltem Gusseisen für mittelschweren und leichten Maschinenguss.) K. W. SCHMIDT. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Aug. 21, 1931, pages 672–673.
Using a small foundry as an example, the means of overcoming the difficulties due mainly to changing temperatures in pouring small quantities of material are outlined. Defects must be found by systematic investigations. By the addition of sufficient Si (about 2.8–3%), very uniform castings can be obtained. Ha(22)

The Casting of Threads. (Das Giessen von Gewinde.) W. SCHAEFER. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, May 22, 1931, pages 424–425.
A few typical cases where threads can be cast on to cast iron pieces are discussed. Economies can be secured in this manner. Ha(22)

Progress in Compressed Air Molding Machines. (Fortschritte in Druckluftformmaschinen.) A. SALMONY. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Apr. 10, 1931, pages 304–306.
Two types of pneumatically operated vibrating molding machines which simplify the work for the molder are described. They are made with box areas of from 1800–8000 cm.^{2} The consumption of air for each box is given to 0.025 m.^{3} at a cost of 0 03 RM for 1 cm.^{3} air. Ha(22)

Foundry Practice. JOHN A. SMEETON. *Iron & Steel Industry & British Foundryman*, Vol. 4, Aug. 1931, pages 355–360; Sept. 1931, pages 391–395, 402.
A discussion of equipment of a modern foundry used for the mass production of castings. CHL(22)

Practical Questions in Calculating the Charge. (Praktische Gattierungsfragen.) H. UHLITZSCH. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, May 29, 1931, pages 433–437.
On the basis of the cast iron diagrams of Maurer which indicates the properties of cast iron as related to the contents of C and Si, an example is calculated in detail to obtain a metal of definite characteristic. It is then shown that this diagram can be used to advantage for additions of Ni and Cr, also. Ha(22)

Some Points on the Storage of Patterns and Accessories. (Einiges über das Aufbewahren von Modellen mit Zubehör.) W. SCHWANERT. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Apr. 10, 1931, pages 300–301.
Some useful hints for the management and operation of foundries with regard to storage of patterns. Improper handling, designation and pattern rooms which are not fireproof are often the causes of considerable loss. Ha(22)

A Simplified Method for Making Special Brasses. (Sur une mode simplifie de fabrication des laitons spéciaux.) AUGUST LE THOMAS. *Revue de Métallurgie*, Vol. 28, Sept. 1931, pages 518–523.
Brasses containing, besides Cu and Zn, some alloying elements principally Ni and Mn furnish a strong and corrosion resistant material which is not expensive. In their manufacture a considerable attention must be paid to the proper composition which must be kept closely to the ratio 60–40 and 58–42 for Cu-Zn, if the best results are desired. The presence of alloying elements is accounted for by using their equivalence number in the calculation of the composition according to the above formula. For simplification of the shop practice, it is much more advantageous to add these additions in the shape of an alloy of the proper composition. Several formulas are proposed for a brass with 5% Ni and 3% Mn, one of which (16.7% Cu, 30.0% Zn, 33.0% Ni, 20.0% Mn) is particularly suitable as easy to handle and not requiring any overheating of the bath. The quality of the brass produced can be easily checked either by a fast metallographic examination or by casting a torsion test which will show by the angle of bend before fracture the composition of the metal sufficiently accurately for practical purposes. JDG(22)

Die-Casting of Brass. (Het Spuiten van Messing in Gietvormen.) P. WEISS & R. WARTENA. *De Gieterij*, Vol. 5, Mar. 1931, pages 30–34.
A description of apparatus for die-casting of brass, made by the firm of Eckert Brothers in Nuernberg (Bavaria). HSvK(22)

Cupola Melting of Brass. T. MAULAND. *Metal Industry*, London, Vol. 38, June 26, 1931, page 644; *Metal Industry*, N. Y., Vol. 29, July 1931, pages 304–305.
Paper read before the American Foundrymens Association. Cupola melting of 85–5–5–5 and 80–10–10 alloys is described. See *Metals & Alloys*, Vol. 2, Oct. 1931, page 229. PRK(22)

Recent Progress in American Manufacture of Malleable Iron. (Progrès récents dans la fabrication Américaine de la fonte malléable.) H. A. SCHWARTZ. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 885–887.
Brief résumé. Describes status of powdered coal, oil, natural gas and electricity as fuels. Sand control, use of permanent molds, mold-conveyor systems are cited as important advances. Efforts to cut down annealing time are discussed. Use of an atmosphere of CO + CO_2 under pressure is being tried out as a means of accelerating annealing. The accelerating effect of Ni, Zn, Al, Ti and U has been demonstrated, and the use of Mo, with higher Si, accomplishes the same result without risk of mottling. Cu may be used for corrosion resistance and the use of Ni or Mo increases the strength. Embrittlement in galvanizing may be avoided by reducing Si and P or by quenching from 600° C. before galvanizing. It has been suggested that the success of the quenching method may be explained on the basis of the presence of N in the metal. The graphitization of malleable is not simply the break-up of cementite, but involves solution of cementite, diffusion of C and the deposition of C in nodules whose number depends on the conditions imposed. Speed of diffusion is the dominant factor. HWG(22)

Practical Calculations for Foundrymen. (Praktische Berechnungen des Giessereimannes.) No. 15 of Hermanns' Betriebspraxis der Eisen-Stahl- und Metallgiesserei. E. SCHÜTZ. Wilhelm Knapp, Halle (Saale), 1931. Paper, 6 × 9½ inches, 198 inches. Price 15 RM.
The calculation of dimensions necessary for hooks, core rods, mold clamps and similar things, the calculation of casting weights from blue prints, the calculations for mixing irons, determination of the cost of molten iron, and many other mathematical problems of the foundry are discussed in great detail with many illustrations. Unfortunately, few of the people in this country who might use such a book to advantage, can read German readily enough to utilize the volume.—H. W. Gillett (22)-B-

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

The abstracts appearing under this heading are prepared in coöperation with the Joint High Temperature Committee of the American Society of Mechanical Engineers and the American Society for Testing Materials.

Cast Iron without Growth for Higher Temperatures. (Wachstumfestes Gusseisen für höhere Temperaturen.) R. Mitsche & O. v. Keil. *Die Giesserei mit Giesserei-Zeitung*, Vol. 18, Mar. 6, 1931, pages 200–204; *Foundry Trade Journal*, Vol. 45, Aug. 20, 1931, page 114.

At temperatures above the critical point, cast iron shows growth which is largely ascribed to the disintegration of iron carbide (increase of volume and inner tensions) and to the α-γ-conversion which also effects a loosening of the structure. The possibilities of avoiding such growth are discussed; an alloy with approximately 6% Si does not show any growth. The tests indicate that such cast iron has the same good mechanical properties as ordinary cast iron. OWE+Ha(29)

Design of Thick-Walled Tubes Subjected to Pressure and Heat Input. E. W. Luster. *Transactions American Society of Mechanical Engineers*, Vol. 53, *Fuels and Steam Power Section*, May-Aug. 1931, pages 161–172.

With the increase in pressure and oil temperature, which have accompanied the development of distillation and cracking equipment in recent years, has arisen the need for a rational method for the design of thick tubes subjected to internal pressure and heat input. Formulas for temperature and pressure stresses in such tubes, and for calculating the optimum tube for given conditions are developed. Examples of calculations are given. The creep apparatus of the author's company is illustrated and described, and the test methods discussed. The apparatus is similar to that of the Union Carbide and Carbon Corporation. A number of the creep data published by other investigators are compared with those obtained by the author's company (Standard Oil Development Co.). Much of the article is mathematical. A study of the formulas show that rational design of thick-walled tubes to be used in elevated temperature service requires a knowledge of the physical properties of the metals used, particularly the creep characteristics. The modulus of elasticity, Poisson's ratio, the coefficient of expansion, and the thermal conductivity also enter into the equations either directly or indirectly, and must be known. It is planned to install a torsion machine by means of which the modulus of rigidity and Poisson's ratio may be accurately determined at both atmospheric and elevated temperatures. A few original data are given on the creep characteristics between 900 and 1400° F. of a 0.12–0.18% carbon steel, a low alloy Cr-Ni-Mn steel and a low-carbon 18 Cr-8 Ni steel. WAT(29)

Measurements with the Aid of Liquid Helium. IX. Resistance of Pure Metals at Low Temperatures. (Messungen mit Hilfe von flüssigem Helium. IX. Widerstand der reinen Metalle in tiefen Temperaturen.) W. Meissner & B. Voigt. *Annalen der Physik*, Vol. 7, 1930, pages 892–936.

The resistance of metals of the 4th periodic group down to Hf; of V, Ta, As, Sb and Bi of the 5th; of Cr, Mo, W, V, Se and Te of the 6th; of Mn and Re of the 7th; of Fe, Ru, Co, Rh, Ir, Pa and Pt of the 8th periodic group was determined from 273° K down to the temperature of liquid He. The characteristic temperatures of these metals were calculated with the aid of the Gruneisen resistance formula. The relation between the characteristic temperatures and the position in the periodic system is tabulated. WAT(29)

Reliability of Steel Boiler Sheets in Marine Service. Correspondence from F. G. Martin, Birkenhead, England. *Metal Progress*, Vol. 20, Oct. 1931, pages 90–91.

The writer discusses the failure of boilers under heading of their probable causes, defective material, bad workmanship, caustic embrittlement and design. WLC(29)

A Study on the Elasticity of Flexure of Iron, Copper, Gold, Silver, Platinum Silica Glass, and Nickel. (Étude sur l'élasticité de flexion, Fer-Cuivre-Or-Argent-Platine-Verre de Silice-Nickel.) A. Jaquerod & H. Mugeli. *Helvetica Physica Acta*, Vol. 4, part 1, 1931, pages 3–30.

Variations in the modulus of elasticity with temperature are given for the above materials. Elasticity-temperature curves are presented for the temperature range of 0 to 140° C. The curves for all of the materials except silica glass are similar to that of steel. Thermal and mechanical treatment produce an increase in Young's modulus, with the exception of Fe and glass which show a decrease. Hooke's law is never entirely followed even for small amounts of deformation. The phenomena exhibited by Ni are discussed. The data are presented both in graphic and tabular form. WAT(29)

Super-Cooling and Formation of Nuclei in Homogeneous Metallic Melts. (Unterkühlung und Keimbildung bei homogenen Metallschmelzen.) A. Lange. *Zeitschrift für Metallkunde*, Vol. 23, June 1931, pages 165–171.

The tendency toward super-cooling was studied in solidifying melts of Sn, Pb and Zn. A new testing method developed by the author was employed. The maximum of super-cooling amounted to 12–14° C. in all 3 metals and the correlation of duration of super-cooling with temperature was established. The problem of nuclei formation is taken up mathematically. The law governing radio-active decomposition was found to hold true in the present investigation. The relationship between crystallization velocity and number of nuclei formed is graphically given and a simple method of producing large single crystals is suggested. ET(29)

Short-Time Test for Metals under Stress at Elevated Temperatures. *Journal Franklin Institute*, Vol. 211, Mar. 1931, page 376.

Abstract from report in *Bureau of Standards Journal of Research*, Feb. 1931. In general results show that "long-time" or "flow" test cannot be satisfactorily replaced by simpler short-time test, although the latter is very valuable for preliminary studies. DTR(29)

Gray Iron Possesses Valuable Engineering Properties. *Foundry*, Vol. 59, Mar. 1, 1931, pages 72–74, 82; Apr. 1, 1931, pages 70–73; June 1, 1931, pages 54–56; Aug. 1, 1931, pages 66–69.

Recent investigations indicate that the view formerly held that gray iron is not pressure-resisting at temperatures above 450° F. is no longer tenable. High quality gray iron can be used safely at temperatures of 600–700° F. and even at 800° F. Tests at temperatures as low as the boiling point of liquid air showed that there is but slight change of tensile strength and hardness. In the design of apparatus for low temperature work, however, the thermal contraction must be taken into account just the same as the expansion in elevated temperatures. Test curves are reproduced. The electrical properties are also noted. Ha(29)

The Choice and Testing of Materials for Highly-Stressed Chemical Plant. *Edgar Allen News*, Vol. 10, Sept. 1931, page 962; *Vancoram Review*, Vol. 2, Oct. 1931, page 147.

For the construction of high-pressure reaction vessels, low C vanadium or molybdenum steels have recently been introduced because they are resistant to aging and are capable of withstanding great mechanical stresses, both at ordinary and elevated temperatures. Steels with 3–5% Ni are also used for this purpose which makes it possible to build the vessels with much thinner walls. Ha(29)

High Pressure in Chemical Industry. E. N. Gougeon. *Journal Society Chemical Industry*, Vol. 50, Apr. 17, 1931, pages 320–321.

A general economic review of industries requiring high temperatures and pressures such as the N, petroleum, natural gas and hydrogenation industries. VVK(29)

Considerations on the Löffler High Pressure Boiler From a View Point of Construction. (Considérations sur la chaudière Löffler a haute pressure au point de vue de la construction.) *Chaleur et Industrie*, Vol. 138, Oct. 1931, pages 537–546.

The steel used in the construction of tubes in the Löffler high pressure boiler is one containing 0.64% Mo. At 550° C. this steel has a creep limit of 5600–7000 lbs./in.², and a tensile strength of 84,000 lbs./in.² The elastic limit is double that of ordinary C steel. WAT(29)

Kanthal Alloy. *Revue Generale de l'Electricite*, Vol. 29, Mar. 21, 1931, pages 91B–92B.

A new alloy named "Kanthal Alloy," has been developed by Mr. H. von Kantzow, general manager of the Boulons Works at Hallstahammar (Sweden). It is an iron alloy containing aluminum, cobalt and chromium. The main characteristics of this alloy are: a high degree of resistance to heat, a low electrical conductivity, and a good capacity for both hot and cold working. It can be used for the production of sheet, tube, wire, or for the manufacture of crucibles. The melting point of this alloy is very high: 1650° C. This new alloy will find an interesting field of application in electric heating where a material of high electrical resistance and elevated resistance to the action of high temperature is required. HWG(29)

Heat Emission from the Surfaces of Cast Iron and Copper Cylinders Heated with Low Pressure Steam. A. C. Willard & A. P. Kratz. *Heating, Piping & Air Conditioning*, Vol. 3, Feb. 1931, pages 141–145.

This paper attempts to explain why a cast iron cylinder with walls 0.25 in. thick will transmit over 50% more heat than a copper cylinder of exactly the same size with walls 0.01264 in. thick, when there is low pressure steam on the inside and air on the outside of the cylinders. Note that the cast-iron cylinder wall is almost twenty times as thick as the copper cylinder wall, and that copper has a conductivity 8 times that of cast iron per inch of thickness. Although the copper wall is $8 \times 20 = 160$ times better than the cast-iron wall as a heat conductor, the overall heat transfer of the cast iron cylinder is greater than that of the copper cylinder because of the greater surface emission of cast iron. The conductivity of the metal may bear little or no relation to the amount of heat emitted from a cylinder made of that metal when filled with saturated steam and surrounded by still air. The actual metal thickness, within rather wide limits, has little or no relation to the amount of heat emitted. The surface finish is an all important factor. The resistance to heat flow from the outer surface of the metal cylinder is relatively enormous when measured in terms of the resistance of the metal wall itself. WAT(29)

Magnetic Properties of Copper-Nickel Alloys. E. H. Williams. *Physical Review*, Vol. 38, Aug. 15, 1931, pages 828–831.

The magnetic susceptibility of alloys of Cu and Ni in proportions ranging from 0.1% to 70% Ni have been studied between 20° and 600° C. X-ray examination of the alloys show that they are homogeneous solid solutions. Although Cu is only weakly diamagnetic it requires 0.8% or 0.9% Ni to neutralize this diamagnetic effect and 56% Ni is required before alloys show ferromagnetic properties at ordinary temperatures. For amounts of Ni from 1% up to 30% the alloy, while paramagnetic in most respects, does not obey any known law of paramagnetism with regard to temperature. As the temperature is increased the susceptibility first increases and then decreases, the maximum occurring in the neighborhood of the Curie point (about 400° C.) for Ni. In the case of alloys containing more than 30% Ni, the susceptibility decreases with increase of temperature for temperatures above 20° C. up to 600° C. WAT(29)

LEACHING (30)

Treating a Complex Ore. Data from Experimental Work on Ores in the Denver Laboratories of the Complex Ores Recovery Co. G. L. Oldright *Technical Paper* 499, *United States Bureau of Mines*, 1931, 101 pages.

The author gives an account of the more salient features brought out in developing a process for the treatment of the ore of the Flin Flon mine in N. Manitoba. He discusses extensive experimental results on roasting, leaching and electrolysis of solutions from an ore analyzing Cu 1.80, Zn 4.65, Fe 34.2, S 38.2, SiO_2 7.7, CaO 2.73, Al_2O_3 1.82, Pb 0.29, MgO 2.38, Mn 0.10, As 0.44, Sb 0.15%, Au 0.12 and Ag 1.7 oz./ton. AHE(30)

Milling, Amalgamation, Cyaniding. Allen J. Clark. *Engineering & Mining Journal*, Vol. 132, Oct. 12, 1931, pages 298–304.

One of the papers of a symposium on "The Homestake Enterprise." Milling in water enhances Au recovery by amalgamation and reduces ultimate residue loss. Cyanicide action is prevented by aeration before the application of cyanide treatment to the 2 parts of a classified pulp, previously ground to a degree permitting maximum metallurgical return. Adequate dewatering of slime before cyanidation by pressure filtration, is an economical and efficient step, the advantages of which deserve wider recognition. A flowsheet of mills and cyanide plants at Lead, S. Dak. and vicinity is shown. WHB(30)

Some Problems in the Treatment of Gold Ores. Staff, Division of Ore Dressing & Metallurgy, Mines Branch, Department of Mines, Canada. *Canadian Mining & Metallurgical Bulletin* No. 235, Nov. 1931, pages 1250–1261.

Problems in the treatment of Au ores of 5 classes are considered. These classes are (1) free milling, (2) free Au plus pyrite, (3) containing Cu, (4) arsenical and (5) containing interfering gangues such as graphitic material, soluble salts, etc. AHE(30)

Flotation Practice at the Calumet and Hecla. Robert M. Haskell (Calumet and Hecla Consolidated Copper Company). *Mining Congress Journal*, Vol. 17, Oct. 1931, pages 528–530.

The ores treated in Calumet & Hecla stamp mills are of 2 kinds, entirely different, (1) conglomerate and (2) amygdaloid. The former is hard and grinding through 200 mesh does not liberate it very thoroughly from gangue, while with the latter, crushing through 48 mesh gives satisfactory extraction. Conglomerate tailings are separated into plus 200 and minus 200 mesh products and only the latter is floated, the coarser sand being ammonia leached. Roughly 1000 tons primary slime, 1400 tons of reground sand and highly variable amount of reclaimed lake slime are treated every 24 hrs. Plant layouts for both types of flotation are described. Name, composition and amount of collectors, frothers and stiffeners used are given in detail. DTR(30)

REDUCTION METALLURGY (31)

Blast Furnace Progress in 1930. R. H. Sweetser. *Blast Furnace & Steel Plant*, Vol. 19, Jan. 1931, pages 101–104.

Brief review of developments and comments on the operation of a few new 1000-ton blast furnaces. The dimensions, equipment of auxiliaries and operating conditions are described. Ha(31)

Blast Furnace Theory and Practice. R. H. Sweetser. *Blast Furnace & Steel Plant*, Vol. 18, Dec. 1930, pages 1824–1826, 1828.

See *Metals & Alloys*, Vol. 2, Nov. 1931, page 287. Ha(31)

Iron Ore Beneficiation. Clyde E. Williams. *Mining & Metallurgy*, Vol. 12, Apr. 1931, pages 186–188.

The author takes the view that the Lake Superior district will continue to lead in the supply of iron ore for decades to come. The ores are beneficiated about 13$^1/_2$% by washing, drying and sintering and 25% by crushing and screening. A review is given of improved furnace practice by reducing the coke consumption of basic iron and of the various grades of lake iron ores. Ha(31)

Direct Methods for Production of Iron. (Die direkte Eisenerzeugung.) F. Wüst. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, *Mining & Metallurgy*, Part 1, pages 481–495.

Includes discussion. Rather general discussion of methods for making wrought iron or sponge iron direct from ores. In discussion Kjerrman briefly refers to Swedish methods. HWG(31)

Heating of Blast Furnace Blast. (Ueber die Bedeutung der Erhitzung des Hochofengebläsewindes und über ihre Auswirkung auf die Ofenleistung.) F. Wüst. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 33. published 1931, *Mining & Metallurgy*, Part 1, pages 449–461.

Discussion of present practice. HWG(31)

The Thin-Walled Blast-Furnaces of the Prague Ironworks Company. J. Sarek. *Engineering*, Vol. 130, Dec. 26, 1930, pages 817–820.

Condensed from paper read before the Iron and Steel Institute, Sept. 15, 1930. See *Metals & Alloys*, Vol. 2, Jan. 1931, page 20. LFM(31)

The Tanier Zinc Furnace. (Le four Tanier.) V. Tanier. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 457–464.

The arrangement of the retorts and the general construction of the furnace are shown in sketches. Temperatures of the different rows of retorts, retort life, etc., are tabulated. The furnace produces 30% more Zn, with $^1/_3$ less fuel, and makes only half as much blue powder as the older type furnace which it replaced. HWG(31)

Reduction Experiments with Minette Ores and Sintered Products. (Reduktionsversuche an Minette- Erzen und Sintergut.) H. Siegel. *Archiv für Eisenhüttenwesen*, Vol. 4, June 1931, pages 557–564; *Stahl und Eisen*, Vol. 51, Aug. 6, 1931, pages 1005–1006.

The author studied the changes which minette ore and sintered products undergo during reduction in a manner so that the experimental conditions were similar to the actual conditions in the blast furnace. Therefore, the ores were gradually heated in 10 hrs. from 200° to 1000° C. and reduced with gas. Ore specimens were analyzed for Fe'', Fe''', Fe_3C and metallic Fe. It was found that carbide is formed directly from the ore at low temperatures (the amount increases up to 600° C.) and decreases at higher temperatures; most pronouncedly between 800° and 900° C. Remarkable amounts of metallic Fe are formed below 700° C. The formation of metallic Fe starts only when the reduction of Fe''' to Fe'' is completed. The state of reduction of ores and sintered products is alike at temperatures around 1000° C. Ores, the reduction of which is completed even at temperatures around 700° C., oxidize again at higher temperatures, so that, in all cases, the O content amounted to from 4 to 6% at 1000° C. GN(31)

Production of Lead-Tin Alloys from Tin Slag. (Die Herstellung von Bleizinnlegierungen aus Zinnschlacken.) Edmund R. Thews. *Metallbörse*, Vol. 21, Jan. 1931, pages 3–4.

Sn slags are smelted with Pb or Sn-poor alloys. A purer product is obtained by using type metal. Pb residues can be used with Sn slags to produce an alloy of 8% Sn. For alloys richer in Sn, this product is oxidized and used as raw material for the next smelt. Sulphurous ores require a preliminary roasting. The presence of much As is harmful because of the formation of viscous iron arsenides. A coking mixture containing 10–25% wood charcoal is best. WHB(31)

Metallurgy of Copper and Cobalt at Katanga. (La métallurgie du cuivre et du cobalt au Katanga.) E. Roger. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 441–456.

Unsuccessful experience with water jacketed furnaces is recounted. The oxidized copper ores are subjected to gravity concentration and flotation and the finely divided product is smelted in reverberatories. Lean ores are leached and the metal recovered by electrolysis. Flow sheets are given and many details described. Cobalt-bearing ores are smelted in water-jacketed furnaces, reducing the Cu and leaving Co and Fe in the scoria, which passes to electric smelting furnaces. Ores high in Co are subjected directly to electric smelting. The smelting process produces an alloy of Cu-Co-Fe which liquates into two separable products, a red alloy of 90–93% Cu, 3–5% Co, 3–5% Fe and a white alloy of 14–17% Cu, 35–45% Co, 35–45% Fe. The process is regulated to produce as much of the white alloy as possible, since the recovery of cobalt from it is easier than from the red alloy. HWG(31)

The Technical Position of the Zinc Industry. O. W. Roskill. *Mining Journal*, London, Vol. 174, Aug. 8, 1931, page 618; Aug. 15, 1931, pages 632–633.

The author describes the Maier process for ZnO reduction by CH_4 and the Coley process for reduction with nascent C from decomposed hydrocarbon oil. Other recent advances are briefly described. AHE(31)

Investigations of Japanese Magnetic Iron Sands. S. Umezu. *Proceedings World Engineering Congress*, Tokyo, 1929, Vol. 33, published 1931, pages 605–638.

In English. The titanium oxide in these sands is in solid solution or present as an intergrowth so that it was found impossible to eliminate more than 50% of the TiO_2 by magnetic separation. Difficulties in reduction due to TiO_2 are commented on. Good micrographs of the ores are shown. HWG(31)

NON-METALLIC COATINGS FOR METALS & ALLOYS (32)

Japanning and Enameling Plant Meets Varied Schedules with Automatic Gas-Fired Ovens. J. B. Nealey (American Gas Association). *Automotive Industries*, Vol. 64, Apr. 1931, pages 582–583.

Ovens are heated indirectly with separate gas-fired heaters, and the hot products of combustion are forced into ovens with motor fans. Work is first put through a burnoff oven to free material of grease, etc. The burnoff oven, a box-like structure of sheet steel and asbestos, is heated directly; temperature of 600–700° F. is used; the burnoff period varies from 15 to 20 mins. This is followed by sanding and wiping. First coat work is baked on in 3 semi-automatic ovens after the material has been dipped in dull finish japan of 29° Be. The second coat is applied and baked on in the fully automatic oven, after being dipped in 30.5° Be japan. All air admitted to the dipping enclosure is filtered and washed while its temperature is automatically controlled by unit heaters. DTR(32)

Enameling of Cast Iron. (L'émaillage de la fonte.) Try-Chalons. *Revue Fonderie Moderne*, Vol. 25, Aug. 25, 1931, pages 305–309.

A detailed description of the production and preparation of pieces suitable for enameling, the preparation of the enamel and the application of the enamel to the cast iron. Wet and dry processes and heating and drying are discussed. Ha(32)

The Modern Painting Method with the Spraying Gun. (Das neuzeitliche Anstrichverfahren mittels der Spritzpistolen.) A. Karsten. *Oberflächentechnik*, Vol. 8, July 21, 1931, pages 153–155.

The development and modern equipment of different manufacturers is described. The pressures applied vary between 1.5 and 3.5 atmospheres. Ha(32)

The Causes of Blisters and Pinholes in Wet-Process Cast Iron Enamel. (Ueber die Ursachen von Blasen und Nadelstichen in Gussnassemaille.) Walter Kerstan. *Giesserei*, Vol. 17, Oct. 3, 1930, pages 965–972.

Plant and laboratory experiments to determine the causes of blisters and pinholes in cast Fe enamels produced by the wet-process. These defects are shown to be due to the simultaneous action of various causes, principal among which are: (1) incorrect composition of the frit, (2) physical defects in the cast Fe, (3) insufficient cleaning of the casting surface and (4) various changes in the Fe structure during the baking of the enamel. Cast Fe in which the graphite is finely divided is the most stable during baking and shows the least change in structure during the enameling process. (32)

Lime Process for Coating Aluminum. Leon McCulloch. *Metal Cleaning & Finishing*, Vol. 2, Oct. 1930, pages 863–864.

From paper read before the American Electrochemical Society. See *Metals & Alloys*, Vol. 1, Feb. 1930, page 390. MS(32)

The Advantage of Thin Organic Protective Coatings. (Der Vorteil dünner organischer Schutzschichten.) P. Nettmann. *Korrosion und Metallschutz*, Vol. 7, June 1931, pages 164–165.

Scientific problems involved in extremely thin surface layers are considered. EF(32)

The Standardization of the Painting Methods in the Manufacture of Automobiles of the Adler Works. (Die Rationalisierung der Lackierverfahren des Automobilbaues der Adlerwerke.) E. Jurthe. *Automobiltechnische Zeitschrift*, Vol. 34, Sept. 30, 1931, pages 601–604.

A description of the mechanical dipping in lacquer is given and a comparison between manual and mechanical methods. Even at 33$^1/_3$% of the full capacity of the plant, a saving of 47.5% can be obtained by the mechanical method. Ha(32)

Rubber Pipe Lining Minimizes Pulp Abrasion. D. D. Homer. *Engineering & Mining Journal*, Vol. 132, Oct. 26, 1931, pages 367–368.

For the transport of tailing, a metal pipe lasted for the passage of 1000 tons, and extra heavy metal pipe for 2000 tons. A rubber-lined pipe showed negligible wear after the passage of about 250,000 tons. WHB(32)

Paint Coatings in Aviation and Their Testing. (Anstrichmaterialien für den Flugzeugbau und deren Prüfung.) O. Merz. *Korrosion und Metallschutz*, Vol. 7, Sept. 1931, pages 217–218.

The various lacquers on the market, their properties, advantages and disadvantages, utilization, etc., are critically discussed with reference to aviation purposes. The paper was presented before the Reichsausschuss für Metallschutz, May 1931. EF(32)

Spraying Finish Coat Sheet-Steel Enamels. *Better Enameling*, Vol. 2, 1931, pages 14–17.

The equipment necessary and the importance of the proper consistency of the enamel are discussed and rules for spraying are given. WAT(32)

MANUFACTURERS' LITERATURE REVIEWS

In this department we each month list the catalogs and other printed matter issued by manufacturers. Unless otherwise noted, any of the items listed may be secured free upon application to the issuing firm. Manufacturers who have not yet sent in their printed matter are invited to do so.

201 **Jig Borers.**—A 32-page booklet of performance data on Swiss High Speed Precision Borers has been sent out by the R. Y. Ferner Co., Washington, D. C. The book is fully illustrated.

202 **Lead.**—The November issue of this publication of the Lead Industries Association, Graybar Building, New York, contains accounts of a number of novel and interesting uses of lead.

203 **Heat Treating.**—An article "Flexibility in Heat-Treating" has been reprinted from *American Machinist* by the Hevi Duty Electric Company, Milwaukee, Wis. Copies may be obtained from the company.

204 **Heat Treating Furnaces.**—Bulletin No. 322 of the W. S. Rockwell Co., 50 Church St., New York, is devoted to their rotary hearth furnaces for heat-treating and forging ferrous and non-ferrous metals. They may be either electric or fuel-fired.

205 **Return Bends.**—Several different types of Ohiolock Frictionless return bends are illustrated in a folder sent out recently by the Ohio Steel Foundry Co., Springfield, Ohio.

206 **Thermometer Controllers.**—Bristol's thermometer controllers for ranges up to 1000° F. are listed in their catalog No. 2025. Their new recorder controllers are also illustrated in this catalog. A price list accompanies it. The Bristol Company, Waterbury, Conn.

207 **Alloy Cast Iron.**—A leaflet issued by the Driver-Harris Co., Harrison, N. J., advertises their "Nichrome" B for addition to cast iron in the making of cylinder blocks, pistons, brake drums, engine sleeves, etc.

208 **Manganese Steel.**—A recent issue of *The Amsco Bulletin*, sent out by the American Manganese Steel Co., Chicago Heights, Ill., is devoted to a variety of applications of manganese steel. Performance data are given.

209 **Electric Telemeters.**—Bulletin No. 27 of the Baldwin-Southwark Corp., Philadelphia, Pa., is descriptive of a group of testing and measuring devices all based on the use of carbon-pile resistors for the measurement of small motions. A technical discussion of the adaptations as well as the limitations of the carbon-pile resistor is included.

210 **Pyrometers.**—The Pyrometer Instrument Co., 103 Lafayette St., N. Y., has issued several leaflets and pamphlets on their new simplified optical pyrometer. Their Bulletin No. 20 explains the principle on which these instruments work and gives directions for using them.

211 **Furnaces.**—The Surface Combustion Corp., Toledo, Ohio, has prepared an attractive pamphlet by collecting a number of their ads which appeared in 1931 and printing them under one cover. Many applications of their special furnaces are shown.

212 **Fire-Brick.**—Mono-line, a plastic fire-brick manufactured by Quigley Company, 56 West 45th St., New York, is described in a booklet issued by the company. Its various uses are illustrated. Another booklet put out by them is devoted to their acid-proof cement.

213 **Steels.**—Wheelock, Lovejoy & Co., Inc., Cambridge, Mass., have prepared a number of leaflets, one devoted to each of their steels. These leaflets give the composition, physical properties, heat treatment, instructions and uses of the steel in question. They are punched for filing in a pocket size note book.

214 **Electric Furnaces.**—Bulletin No. 7 of the Ajax Electrothermic Corporation, Trenton, N. J., is devoted to the Ajax-Northrup oscillator or spark-gap type converters and furnaces. It discusses the general principles of this equipment and is profusely illustrated.

215 **Industrial Regulators.**—The Minneapolis-Honeywell Regulator Co., Minneapolis, Minn., has published a condensed catalog on their electric motor operated valves to regulate the flow of steam, air, water, gas, oil, etc. Separate bulletins fully describing the operation of each device can be obtained from the company.

216 **Recuperators.**—Bulletin No. 3114 of the Duraloy Co., 26th St., Pittsburgh, Pa., contains information valuable to users of furnace recuperators wherein extremely high temperatures are involved. Cross-section diagrams of this type of recuperators are given.

217 **Electro-tinning.**—A compact booklet compiled by the Roessler & Hasslacher Chemical Co., Niagara Falls, N. Y., contains information on the composition and preparation of the sodium stannate-acetate solution, operating conditions, methods of control and other data of interest on the electrotinning process.

218 **Machine Tool Castings.**—The December issue of *Nickel Cast Iron News*, published by the International Nickel Co., 67 Wall St., N. Y., features an article entitled "Better Machine Tool Castings." It also contains No. 10 of their Intimate Chats on Metallography.

219 **Gas Furnaces.**—Bulletin No. 16 of the American Electric Furnace Co., 27 Von Hillern St., Boston, Mass., is devoted to the Juthe gas furnaces with atmospheric control. A section plan of the furnace is shown.

220 **Rhodium Plating.**—The H. A. Wilson Co., 97 Chestnut St., Newark, N. J., has recently printed a pamphlet on their rhodium plating solution. They are prepared to furnish a small plating outfit for a moderate price.

221 **Inhibitor Acid.**—A folder describing their Inhibitor Acid has been issued by the Merrimac Chemical Co. Inc., Boston, Mass.

222 **Thallium.**—The January issue of the *Industrial Bulletin*, published by Arthur D. Little, Inc., Cambridge, Mass., contains a short item on this rare element.

223 **Facts on Soldering.**—A most attractive booklet compiled by the Kester Solder Co., Chicago, Ill., contains much information on soldering. Some of the chapter headings are Fluxes, Solders, Soldering Equipment and Applications of Solders and Flux.

224 **Roll Lathes.**—Bulletin L-1201 of the United Engineering and Foundry Co., Pittsburgh, Pa., is devoted to their heavy duty roll lathes. Excellent illustrations and cross-section diagrams of the equipment make this an unusually interesting pamphlet.

225 **Gage Blocks.**—C. E. Johansson, Inc., Division of Ford Motor Co., Detroit, Mich., has recently issued a catalog on their gage blocks and accessories. These gage blocks are said to be accurate within a few millionth parts of an inch. A price list is included.

226 **Optical Instruments for Examining and Analyzing Metals.**—A 125-page book prepared by the Bausch & Lomb Optical Co., Rochester, N. Y., is an optical handbook for the metallographer, including articles, tables and references compiled by their Scientific Bureau. It includes very complete optical information for the metallographer, as well as a discussion of ultra violet photomicrography and an article on spectrographic analysis.

227 **Lead.**—The January issue of this publication of the Lead Industries Association, Graybar Building, New York, features an article on lead pipe with compression fittings. It also describes the use of lead walls as a protection against X-rays.

228 **Springs.**—The December issue of *Mainspring*, published by the Wallace Barnes Co., Briston Conn., contains the second installment of an article on "Flat Springs." Charts and tables add to the usefulness of this discussion.

229 **Hack Saws.**—A leaflet sent out by Joseph T. Ryerson & Son, Inc., Cambridge, Mass., includes a list of their high speed hand and power blades.

230 **Furnaces.**—Bulletin No. 220 of H. O. Swoboda, Inc., Pittsburgh, Pa., illustrates their "Falcon" Straight Line Continuous Electric Furnaces arranged for hardening and tempering strip steel.

231 **Castings.**—The December issue of *Better Castings* issued by the Niagara Falls Smelting & Refining Corp., Buffalo, N. Y., contains a list of their alloys with suggested uses for each one.

232 **Temperature Controls.**—Bulletin No. 1212 of the Automatic Temperature Control Co., Inc., 34 East Logan St., Philadelphia, Pa., is devoted to their time cycle contractors of several types: The manually operated cycle stop type, the semi-automatic cycle stop type, the automatic cycle repeating type and the cycle program type.

233 **News about Anaconda Metals.**—The January issue of this periodical which is sent out by the American Brass Co., Waterbury, Conn., contains a number of articles discussing the uses of Everdur and different types of bronze.

234 **Grinding.**—The November issue of *Grits & Grinds*, house organ of the Norton Company, Worcester, Mass., has in it several interesting articles: Gauges Increase Grinding Production and Reduce Scrap Work, Effect of Grinding Pressures on Bakelite and Rubber Snagging Wheels, and Laps and Lap Care for Accurate Work.

235 **Piping.**—A recent issue of the *National Bulletin*, a publication of the National Tube Co., Pittsburgh, Pa., features a well-illustrated article "National Pipe for Power Piping." Several pages of the Bulletin are devoted to tables showing the properties of supersaturated and superheated steam.

236 **Metal Melting.**—The use of the Kemp Immersion melting equipment is recommended for melting such soft metals as lead, tin, pewter, type metal or solder. According to this system the heating units are placed inside of the metal to be melted instead of outside of the pot which is said to effect great economy and efficiency.

237 **Bonding Material.**—The General Electric Co., Schenectady, N. Y., has sent out reprints of an article which originally appeared in their *General Electric Review*. It is entitled "Glyptal in the Foundry" and discusses the advantages of this material as used in making cores in the foundry.

238 **Furnaces.**—The American Electric Furnace Co., Boston, Mass., has recently issued a folder describing their high speed electric furnace with controlled atmosphere. A diagram shows how the atmospheric control works.

239 **Promal Castings.**—The Link-Belt Co., Indianapolis, Ind., is distributing an attractive book devoted to Promal castings. Promal is a metal suitable for many industrial castings and is described and illustrated in this new book, No. 1250.

240 **Udylite.**—The December issue of *The Udylite News*, published by the Udylite Process Co., Detroit, Mich., tells about the use of this rust-proofing process in fire-alarms and in steel lockers.

241 **Furnaces.**—Leaflet GEA-1495 of the General Electric Co., Schenectady, N. Y., discusses their Bell-type furnaces for bright-annealing coiled steel strip. Leaflet GEA-1324A is devoted to their air-draw furnaces for the quantity drawing of steel parts at temperatures up to 1200° F.

242 **Lead.**—The February issue of the Copper & Brass Research Association Bulletin illustrates the application of lead-coated copper to roofings on various types of important buildings throughout the United States.

243 **Electric Heating Equipment.**—Catalog 247 of the Westinghouse Electric & Mfg. Co., is a most useful 100-page bulletin devoted to their electric furnaces, ovens, melting pots, heating elements and heating controls. Each item is illustrated and is accompanied by production curves and specifications. The first few pages give useful definitions of terms relating to heat treatment operations.

244 **Material Handling.**—Data Sheet No. 5 of the Link-Belt Company, Chicago, Ill., contains a chart giving sizes of shafts for combined torsion and bending.

ALPHABETICAL INDEX TO ADVERTISERS

*"MA" refers to Current Metallurgical Abstract Section. "A" refers to Advertising Section.

◆ ◆ ◆

Frederick Samuel Jordan, sales manager of the nickel department of the International Nickel Company, Inc., 67 Wall Street, died suddenly on Dec. 16, 1931, of a cerebral hemorrhage at his home, 30 Fifth Avenue, after an illness of less than a day. Mr. Jordan was 62 years old.

Born in Berea, Ohio, on Aug. 28, 1869, Mr. Jordan attended the Cleveland Business College and commenced his career when he was 18 in the Cleveland offices of the Big Four Railroad. A year later he became private secretary to H. P. McIntosh, an executive of the Canadian Copper Company. The company merged into the organization of the original International Nickel Company in 1902 and Mr. Jordan came to New York as a sales executive.

Mr. Jordan was a member of the Bankers' Club, the North Hills Golf Club and the Ohio Society.

On recommendation of the Board of Awards, the Board of Directors of the American Foundrymen's Association has approved the presentation of the W. M. MacFadden and John A. Penton Gold Medal Awards to Dr. H. W. Gillett, Director of Battelle Memorial Institute, Columbus, Ohio, and L. W. Spring, Chief Chemist and Metallurgist, Crane Company, Chicago, respectively, for their outstanding services to the foundry industry. These two medal awards, which will be presented at the 1932 convention of the A. F. A. at Philadelphia next May, are two of four medal awards which were established through grants of funds by four post officers of the A. F. A. in 1920. The Board of Awards, which selects the recipients of these medals, consists of a committee of seven past presidents of the Association. Mr. Spring is a member of the Editorial Advisory Board of METALS & ALLOYS.

GENERAL (0)

Metallurgical Fundamentals Present and Future. Chas. G. Maier. *Mining & Metallurgy*, Vol. 12, June 1931, pages 280-284.
The author emphasizes the necessity of accurate and complete knowledge of the properties of matter and of the energy involved in physical and chemical changes because this is the first requisite of metallurgical progress. The training of metallurgists should primarily follow these lines. These ideas are illustrated by examples of application of theory, later verified by experiment. Ha (0)

Chemical Composition as a Basis for Classifying Steel Castings. R. A. Bull. *Iron Age*, Vol. 128, July 16, 1931, pages 174-175, 207.
The adoption of definite chemical limitations for the definition of products of the steel foundry is suggested instead of the present indefinite designations such as "low carbon," "high-alloy," "regular alloy steel," etc. See *Metals & Alloys*, Vol. 2, Dec. 1931, page 321. Ha (0)

The Distribution of the Platinum Metals in the Earth-Crust (Die Häufigkeit der Platinmetalle in der Erdrinde). I. & W. Noddack, *Zeitschrift für physikalische Chemie*, Bodenstein Festband, 1931, pages 890-894.
The investigators extended their research work on the geo-chemistry of Rhenium (see *Metals & Alloys*, Vol. 2, Nov. 1931, page 241) to the analyses of the Pt-metals in their carefully collected samples and computed therefrom the distribution of the Pt-metals in the cosmos. The share of the metals listed in Column 1, in the sun's system is given in Column 2 in the table below, whereas Column 3 collects the occurrence on this earth. Column 4 shows the "impoverishment factor," i.e. the ratio between the contents of the Pt-metals in the center parts of the earth and the earth crust. The data evaluated are confronted with former statements of other scientists and are critically discussed.

Metal	Occurrence in the cosmos	Occurrence on the earth	"Impoverishment Factor"
Ru	9×10^{-6}	1.8×10^{-8}	500
Os	3.9×10^{-6}	3.2×10^{-8}	122
Rh	1.9×10^{-6}	2.2×10^{-8}	86
Ir	0.9×10^{-6}	2.1×10^{-8}	43
Pd	7.0×10^{-6}	1.2×10^{-8}	583
Pt	7.0×10^{-6}	5.0×10^{-8}	140

EF (0)

Chemical Engineering Catalog. Chemical Catalog Company, New York, 1931. Cloth 9x12 inches, 1017 pages. Price $3.00. Free of charge to operating officials subject to return upon publication of new edition.
The Sixteenth Annual Edition of the Chemical Engineering Catalog sustains the high standards established by preceding issues. The sections of this volume are the same as those last year, namely: 1. Alphabetical list of firms cataloged. 2. Trade Name Index. 3. Classified Index of Equipment and Supplies. 4. Equipment and Supplies Section. 5. Classified Index of Chemicals and Raw Materials. 6. Chemicals and Raw Materials Section. 7. Technical and Scientific Books Section.
The material contained in these sections has been carefully cross-referenced and is a convenient source of information for those interested in machinery, laboratory supplies, heavy and fine chemicals and equipment.
M. L. Moorman. -B-(0)

Transactions of the American Institute of Mining & Metallurgical Engineers, Petroleum Division, 1931. Institute of Mining & Metallurgical Engineers, New York, 1931. Cloth, 6x9½ inches, 657 pages. Price $5.00.
This volume contains 65 papers covering much of the newer technical information on unit operation, petroleum engineering, research engineering, economics and world production. These papers were presented at the 2 fall meetings of the Petroleum Division, A.I.M.E., held in Tulsa, Oct. 2 and 3 and Los Angeles, Oct. 17, 1930, and the annual meeting in New York City in Feb. 1931. -B-(0)

The Open Hearth versus the Steel Plant. *Blast Furnace & Steel Plant*, Vol. 18, Oct. 1930, pages 1619-1623.
The quality of the steel supplied by the open hearth to the steel plant for further manufacture is the basis of the entire steel trade. The consumer frequently abuses his steel beyond the proper limits, causing serious defects. The quality of steel made in the open hearth depends on the kind of scrap charged, percent of scrap, delivery of hot metal to the open-hearth furnace when needed, amount and kind of limestone used, fuel, evenness of flow of fuel, attention and ability of operators and pit practice. In the steel plant, the determining factors include the proper timing of delivery to soaking pits, rolls, reduction in rolling with regard to temperature of the ingot, temperature control, etc. All of these factors are briefly discussed. Ha (0)

Metals and Alloys. Louis Cassier Co., Ltd., London, 1931. Cloth, 6x9 inches, 136 pages. Price $2.65.
The previous edition contained the percentage compositions of some 500 metals and alloys, while the present book lists about 3500 alloys. The listing is alphabetical beginning with accumulator metal (which on this side would be storage battery lead), and ending with ziskon, a metal containing 40% Zn and 60% Al. In many instances the alloys are listed under a collective head, and under a trade name. For example under acid resisting alloys the name ferron appears and it is found also in its proper place alphabetically.
While the book is entitled *Metals & Alloys*, the headings of the tables giving the compositions are "Percentage Compositions of Nonferrous Alloys" which would lead one to believe that only nonferrous alloys are listed. However, quite a number of alloys containing 50% and over of Fe are mentioned such as calite, Krupp V2A steel, etc. R. Rimbach (0)-B-

Developments in Ferrous and Non-Ferrous Metallurgy during 1930. H. M. Boylston. *Fuels & Furnaces*, Vol. 9, Jan. 1931, pages 19-31.
A review of progress made in materials and equipment in this field. Ha (0)

PROPERTIES OF METALS (1)

The Electric Conductivity of Copper (Ueber die elektrische Leitfähigkeit von Kupfer). G. Elsner & P. Siebe. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Feb. 28, 1931, page 267.
See *Metals & Alloys*, Vol. 2, May 1931, page 94. Ha (1)

Valence Forces in Lithium and Beryllium. J. H. Bartlett, Jr. & W. H. Furry, *Physical Review*, Vol. 38, Nov. 1931, pages 1615-1622.
With the nodeless wave functions of Guillemin and Zener, the method of Heitler and London is applied to determine how 2 normal Li atoms, and also 2 normal Be atoms, influence each other (as a function of the distance). For the diatomic Li molecule in the ground state, the equilibrium distance is calculated to be 2.4A.U., and the heat of dissociation to be 1.09 volts. The experimental values are 2.67A.U. (Harvey and Jenkins) and 1.14 volts (Loomis and Nusbaum), respectively. 2 normal Be atoms repel each other. WAT (1)

Ultraviolet and Light Reflecting Properties of Aluminum. A. H. Taylor & Junius D. Edwards. *Journal Optical Society of America*, Vol. 21, Oct. 1931, pages 677-684.
3 methods of etching Al are described: with hydrofluoric acid, with sodium-hydroxide-sodium fluoride and with sodium hydroxide-sodium chloride-hydrofluoric acid. All 3 produce partially diffusing surfaces with high reflection factors for both light and ultraviolet radiation. For the former, the factors range between 82 and 87% and for ultraviolet radiation at λ 2967 from 81 to 82%. A table of diffuse reflection factors for differently treated samples of Al is given. 8 references. Ha (1)

Elastic Modulus, Temperature and Melting Point of Metals (Elastizitätsmodul, Temperatur und Schmelzpunkt). W. Widder. *Physikalische Zeitschrift*, Vol. 32, Apr. 1931, pages 349-351.
The change of the elastic modulus as a linear function of the temperature, which at the melting point is zero, was established in earlier work by the author. The original relation $E_t = A \cdot e^{-\frac{B}{T - t}}$ was compared with results of recent measurements by a number of investigators over a wide temperature range. Values of the constants were calculated by the method of least squares for Fe, Ni, Al, Au, Pb, Sn, Ag, and Pt. (1)

Lead. G. W. Thompson. *Mining & Metallurgy*, Vol. 12, Apr. 1931, pages 195-198.
The growth of consumption due to electrical and automotive industries, the Harris process of softening lead, improvements in cable sheathing, hardness are discussed and explained. Ha (1)

The Change of Electric Resistance of Purest Electrolytic Iron in Transverse Magnetic Fields (Die elektrische Widerstandsänderung von reinstem Elektrolyteisen in transversalen Magnetfeldern). O. Stierstadt. *Zeitschrift für Physik*, Vol. 67, Feb. 25, 1931, pages 725-742.
It can be assumed that the total changes of resistivity of a ferro-magnetic material are due to 2 causes. One occurs in any metallic conductor and increases the resistance in longitudinal and transverse fields. The other is specifically for ferro-magnetic materials and produces a reduction of the resistance. The change depends on the temperature and, therefore, the temperature will determine whether one effect or the other will be the stronger. At the Curie point, the second effect is more powerful; at lower temperatures, the former effect, so that even the sign may be changed. Ha (1)

Hall Effect in Liquid Metals (Halleffekt in flüssigen Metallen). J. Kikoin & Ibrahim Fakidow. *Zeitschrift, für Physik*, Vol. 71, Aug. 29, 1931, pages 393-402.
Statements are frequently met in literature that the Hall effect does not exist in metals. Experiments with Hg and K-Na alloys showed, however, that the Hall effect could be observed in metals and is of the expected order of magnitude and sign (—) in K-Na alloys; in Hg, it is immeasurably small. JGT (1)

Beryllium, a New Industrial Metal. J. Becker. *Engineering Progress*, Vol. 12, Oct. 1931, pages 229-230.
Beryllium, atomic number 4, density 1.84, melting point 1280° C., is harder than glass. It is usually used now in alloys with Cu, Co and Ni; the Be content does not exceed 3%, so the present high price of Be is not prohibitive. Heat treatment improves the toughness. Beryllium bronzes, especially heat-treated, are much stronger than aluminum bronzes and approach the strength of good spring steel. Beryllium bronze has a high elasticity and shows very little sign of fatigue. The electrical conductivity of a 2.5% bronze is about 17 to 19 as compared with 7 to 10 of phosphor bronze; its thermal conductivity is 0.4 (electrolytic copper is 1). A bronze with from 0.9 to 1.5% Be has been found to be excellently adapted as a bearing metal because it showed only about 1/6 of the wear of tin bronze. Ha (1)

A Revision of the Atomic Weight of Thallium. Henry Aird Briscoe, Suetaro Kikuchi & John Buttery Peel. *Proceedings Royal Society*, Vol. 133A, Oct. 1931, pages 440-457.
The results are closely comparable with the data of Hönigschmid, Birckenbach and Kothe, both in the value of the atomic weight deduced and in the deviation of individual analyses from the mean. Their final value deduced from 24 analyses, is Tl = 204.39 with an average deviation from the mean $\pm$ 0.012, while the value reported in the present paper is Tl = 204.34 with an average deviation $\pm$ 0.015. The method employed amounted simply to fusing thallium chloride.
WAT (1)

Hafnium and Rhenium, or the Metals of the Future. *Technology Review*, Vol. 33, July 1931, page 459.
The practicability of the 2 new elements concerns the high melting point and electronic emissivity of Hf which is used in radio tubes, incandescent electric lamp filaments and cathode surfaces of X-ray tubes and rectifiers. Its cost is $25/g. The melting point of Re, 3440° C., makes it very useful in radio and television apparatus, but it also is very expensive. MAB (1)

Aluminum Bronze Die-Castings. *Metallurgia,* Vol. 4, Oct. 1931, pages 171, 172, 200.

Permanent mold aluminum bronze castings weighing from 1 oz. to 10 lbs. are now being produced. The alloys containing from 10 to 12% Al are resistant to many corrosive agents. They are also susceptible to heat treatment. A 10% Al alloy has a tensile strength of 30-35 tons/in.^{2} and an elongation of 15 or 20% in 2 ins. After quenching from 900° C., it will have a strength of 48 tons/in.^{2} with an elongation of 2% and, after tempering at 800° C., the strength will fall to 38 tons/in.^{2} while the elongation increases to 34%. No dressing is used on the molds and, with careful handling, the molds should last for at least 10,000 or 15,000 castings. Cast iron is usually used for the molds but alloy steel dies have a longer life. JLG (2)

Torsional Strength and Torsional Rigidity of Aeroplane Parts (Die Verdrehfestigkeit und Verdrehsteifigkeit von Flugzeugbauteilen). Heinrich Hertel. *Luftfahrtforschung,* Vol. 9, Aug. 1, 1931, pages 1-56.

The purpose of this investigation was to determine the torsional rigidity and the elastic axis of the constructional parts of aeroplanes. The test pieces are preferably made of materials used in the construction, i. e., woods and light metals, and have the usual sections, i. e., boxes with thick and thin walls, pipes with and without intermediate walls and with perforated walls. On the basis of these tests and of calculations, directions are given which make an exact and simple determination of the torsional rigidity and torsional tensions of these bodies possible. The rotation axis of the bodies is also determined. Part of the tests have been carried through until fracture occurred; the various shapes of fractures and their causes are described. The torsional rigidity is the product of the twisting resistance which depends only on the section; the modulus of shearing is purely a property of the material. By systematically changing the sections in the tests with wood, the modulus of shearing for wood, so far unknown, was determined for parallel and diagonal arrangement of the fibres. Only very great deviations from normal temperatures and humidity had an appreciable influence on the modulus of shearing of the wood. The torsional rigidity of the constructional parts is of determining influence on the total rigidity and the vibration properties of the plane. The test methods, their theoretical principles and the results are described in detail. A list of literature is appended. Ha (2)

Monel Metal: Production, Properties and Applications. Norman C. Marples. *Chemical Age,* London, Vol. 22, Mar. 22, 1930, pages 263-264.

Physical and mechanical properties, corrosion resistance, applications in the chemical industries and miscellaneous uses are discussed. VVK (2)

Engineering Silver Solders. *Metallurgist,* Feb. 1931, pages 23-24.

The Ag-Cu-Zn alloys are thoroughly discussed, particularly the work of Shuzo Ueno (*Memoirs College of Science Kyoto Imperial University,* Vol. 12, 1929, pages 347-374) who gives a complete equilibrium diagram; and of R. H. Leach (*Proceedings American Society Testing Materials,* 1930) who gives the physical properties of these alloys. VVK (2)

The Dimensional Stability of Heat-Treated Aluminum Alloys. J. D. Grogan & D. Clayton. *Journal Institute of Metals,* Vol. 45, No. 1, 1931, pages 157-186; condensed in *Engineering,* Vol. 131, Mar. 13, 1931, pages 371-373; abstract in *Engineer,* Vol. 151, Mar. 27, 1931, page 340.

This paper, which was read before the Institute of Metals, Mar. 12, 1931, as it appears in the *Journal of the Institute of Metals* is accompanied by discussion. Discussion is also included in *Engineering,* Vol. 131, Mar. 20, 1931, page 383. See *Metals & Alloys,* Vol. 2, July 1931, page 126. LFM (2)

The Production and Applications of High-Nickel, Nickel-Copper Alloys and Pure Nickel in Industry. N. C. Marples. *Metal Industry.* London, Vol. 37, Nov. 21, 1930, pages 485-487, 490; *Foundry Trade Journal,* Vol. 43, Nov. 20, 1930, pages 353-354.

From paper read before the Scottish section of the Institute of Metals in Glasgow. Ni-Cu alloys were used as early as the 3rd century, B. C., while metallic Ni was not discovered until 1751. Highest mechanical properties in Ni-Cu alloys were obtained from alloys whose Ni content was between 60 and 80%. This group of alloys have an outstanding representative in Monel metal. Pure Ni is used as an additional element in ferrous and non-ferrous alloys; as anodes for plating; and as malleable Ni in form of rod, sheet, strip, wire, tubing, etc. Monel metal properties are: ultimate tensile strength, 40-45 tons/in.^{2}; yield point, 35-38 tons/in.^{2}; proportionality limit, 28-30 tons/in^2; elongation, 20% on $4\sqrt{\text{area}}$. Additional properties discussed were: corrosion resistance, strength at high temperatures and various applications. VSP (2)

A Study of Tin-Base Bearing Metals. II. G. B. Karelitz & O. W. Ellis. *Metal Industry,* London, Vol. 36, Feb. 14, 1930, pages 197-201.

Condensed from paper read at the annual meeting of the American Society of Mechanical Engineers at New York, Dec. 2 to 6, 1929. Discusses the mechanism of wiping of babbitt linings and certain phenomena observed during the casting of tin-base alloys. See also *Metals & Alloys,* Vol. 2, Oct. 1931, page 205. VSP (2)

A New Aluminium Alloy. *Automobile Engineer,* Vol. 21, Sept. 1931, page 356.

The Birmingham Aluminium Casting, Ltd., has developed an alloy unaffected by ordinary atmospheric conditions of a specific gravity of 2.68. It forms a corrosion-resisting film and the claim is made that it is particularly useful for marine purposes. Castings have a yield point of 5-7 tons/in.^{2} and an ultimate strength of 14-15 for chill cast bars; 9-10 tons/in.^{2} for sand cast bars. Brinell hardness is 54-58. It is exceedingly suitable for extruding and rolling with higher values as for casting. Ha (2)

Gray Iron Possesses Valuable Engineering Properties. *Foundry,* Vol. 59, May 1, 1931, pages 58-61, July 1, 1931, pages 61-63.

Sixteenth article of a series. Gray iron resists many corrosive fluids used in manufacturing plants. Nature of fluid, concentration, temperature pressure and pressure of impurities all have an influence on the corrosive action. Oils with high S content are corrosive. Strong acid lowers corrosive attack. Wear resistance depends on various factors. Abrasives promote heavy wear. Under certain conditions, gray iron castings may contain chilled edges due to fins, improper analysis and other causes. Combined and total C and P affect machinability of gray iron. Alloys which promote graphitization, such as Ni, Al, etc., increase machinability while those that inhibit disintegration of carbides, such as Cr, diminish it. Good cupola operation is beneficial in obtaining uniformity in machinability. Poor tool material, improper heat treatment, incorrect grinding, poor setup, etc., are also sources of trouble. VSP (3)

German Special Steels. Ernest Pohl. *Engineering Progress.* Vol. 12, Jan. 1931, pages 1-6.

Physical properties, analyses and treatment of the following steels are given: open-air corrosion-resisting and stainless steels, structural steels, steel for boilers and chemical apparatus, steel for machine parts, for anchor chains, magnetic steels and tool steels. Ha (3)

One Per Cent Copper Steel has Desirable Physical Properties. H. B. Kinnear. *Iron Age,* Vol. 128, Sept. 24, 1931, pages 820-824.

Conclusion of an article appearing in *Iron Age,* Sept. 10, 1931. "Jump" in Cu steels first appears with Cu content of 0.50% and increases up to 0.90%, after which it decreases until it disappears at 5% Cu. Cu seems to produce the same hardening effect when in combination with such alloys as Mo, Cr, V and Zr. Cu steels may be forged. In conclusion: (1) Cu lowers the A_3 point; (2) Cu in steel or gray iron produces fine grained structures; (3) no evidence of red shortness in shafting forged from sand cast ingots of 1% Cu steel low in S is seen. Includes bibliography. VSP (3)

Manufacture, Properties and Uses of 18-8 Chromium-Nickel Wire. W. H. Wills & J. K. Findley (Ludlum Steel Co.). *American Society for Steel Treating, Preprint* No. 27, 1931, 16 pages.

Paper read and discussed before the Boston Convention of the Society in Sept. 1931. The authors illustrate their description of the process of drawing this material into wire with 6 micrographs and cite 3 references. The properties and uses of the wire are reported and discussed. WLC (3)

Forming and Fabrication of Stainless Steels. Edward Houdremont. *Metal Stampings,* Vol. 4, Feb. 1931, pages 117-118.

Abstract of an article translated from *Stahl und Eisen.* See *Metals & Alloys,* Vol. 2, Mar. 1931, page 63. JN (3)

High Grade Chromium-Nickel Steel Castings (Ueber hochwertigen Chrom-Nickel Stahlguss). Viktor Zsak. *Giesserei,* Vol. 16, Mar. 1, 1929, pages 193-205.

Paper reporting an extensive series of experiments on Ni-Cr steel castings containing Ni 3.00-3.75, Cr 0.55-0.95%; data are presented on the mechanical properties and microstructure of castings in various conditions. The results of the experiments recorded lead to the conclusion that in steels of the composition under consideration very good mechanical properties may be obtained by accurate control of the conditions of casting, combined with a simple annealing treatment. It is preferable, however, to use the material in the more thoroughly heat-treated state, i.e., in the hardened and tempered condition, since such treatment further enhances the mechanical properties of the original material and eliminated variations in composition and structure which may exist in the untreated steel. (3)

Iron-Nickel-Chromium System. Walter A. Dean. *Heat Treating & Forging,* Vol 16, Oct. 1930, pages 1285-1288, 1291.

From thesis submitted to Rensselaer Polytechnic Institute. See *Metals & Alloys,* Vol. 1, Dec. 1930, page 900. MS (3)

Classifies Gray Iron Mixtures. *Foundry,* Vol. 59, May 1, 1931, pages 61-63.

Abstracted from *Bulletin No. 3 of Gray Iron Institute.* Gives additional results obtained from a series of test bars. VSP (3)

Copper Steels, their Corrosion Resistance (Les aciers au cuivre, leur resistance a la corrosion). *Cuivre et Laiton,* Vol. 4, June 30, 1931, pages 275-285.

A comprehensive review of sheets, tubes and other products of steels containing from 0.03 to 0.3% Cu. The test results of American and German laboratories are cited showing that the average corrosion loss in air of ordinary steel was about 2 to 3 times more per ft. exposed than with Cu steel. The losses by attack from various acids (organic and inorganic) amounted to 23-70% of ordinary steel. A special steel of 0.3-0.5% Cu and 0.4-0.6% Cr had the following properties: tensile strength, 54-60 kg./mm.^{2}, elastic limit 36-41 kg./mm.^{2}, elongation 22-28%. A list of the very extensive fields of application is added. Ha (3)

High Strength Cast Iron Keeps Pace with the Times. *Machine Design,* Vol. 3, Feb. 1931, pages 49-50.

The Gunite Corporation, Rockford, Ill., manufactures an air furnace pearlitic iron of greater fineness and more uniform distribution of graphite carbon particles. The result is higher strength so that much can be gained in lighter sections. A few characteristic curves are given. Ha (3)

Alloy Structural Steel. *Vancoram Review,* Vol. 2, Oct. 1931, pages 123-126.

The analysis of a few alloyed V steels are given which are to take the place of the normal soft C steel for structural purposes. These steels contain Mn, Si, Cr and V and show a remarkably high yield ratio, which varies, for the different kinds, between 0.66% and 0.78%; while in soft C steel it is about 0.6%. A few remarks on cold working for fabrication and the attending changes are added. Ha (3)

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Corrosion Testing. *Metallurgist*, Jan. 1931, pages 2-3.
The present large number of accelerated corrosion tests, based on various fundamental phases of the corrosion reaction and also based on exposure to various media indicate that the time is not yet ripe for a standardized corrosion test. Until our knowledge of the fundamental "corrosion resistance," if such exists, of a material is sufficiently accurate so that different observers will not get conflicting results, the introduction of "standard" corrosion tests is to be deprecated. VVK (4)

The Action of Bacteria in the Tuberculation of Water Mains. H. G. Reddick & S. E. Linderman (U. S. Pipe and Foundry Co.). *Water Works Engineering*, Vol. 84, Nov. 18, 1931, pages 1611-1612, 1622-1624.
A tubercule is a growth of a limpet-like structure on the surface of iron. These incrustations consist of a cone-like structure which grows by the addition of concentric layers. The central portion is black and soft when fresh and contains iron sulphide. The middle layers are composed of ferric oxide, while the outside layers are composed of ferric oxide interspersed with hard black layers of magnetic oxide of iron. Several analyses of tuberculation specimens are given and all show a close analogy to typical bog ore analyses. They also are magnetic, contain water of hydration and are nodular, as are bog ores and limonites. Since bog ores and limonites are results of bacterial deposition, tuberculation is thought to be a result of bacteria. Suitable cultures were made up, bacteria were cultivated and their ability to collect iron was demonstrated. CBJ (4)

Pitting in Worm Gears. H. Walker. *Automobile Engineer*, Vol. 21, June 1931, pages 223-224.
An investigation into the cause of pitting which occurs almost invariably on the leaving side of the tooth. This investigation led to the probable explanation that certain spots on the worm-thread surfaces come into contact twice during each passage of the thread across a wheel tooth and that during the first contacts, the worm-thread surface may be amply lubricated while during the second contact it is quite possible that sufficient lubricant may not be present to give an oil film because the lubricant may have been squeezed from the surface during the first contact. The facts bear out this explanation, because the pitting takes place at the part of the wheel of the second contact. Ha (4)

Corrosion Tests on Pure Aluminum and its Alloys (Essais sur la corrosion de l'aluminium pur et de ses alliages). A. von Zeerleder & E. Zurbruegg. *Congres International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 599-610. 21 figures.
Tests by the Mylius rise-of-temperature method, by the gas evolution method, by loss of weight in various acids and solutions, by tensile tests after exposure to salt spray, and by measurement of electric potential are tabulated and plotted, for Al of varying purity, for the alloy with 1½% Mn, and for several strong, heat-treated alloys as well as some casting alloys. No conclusions are drawn as to the ability of the different alloys to withstand different corrosive conditions in actual service, or as to the correlation between the laboratory tests and service results. The data are given to illustrate the various type of corrosion testing methods. See also *Metals & Alloys*, Vol. 2, Oct. 1931, page 208. HWG (4)

Influence of Variations in Heat-Treatment and Ageing of Duralumin. A. von Zeerleder (Eidgenössische Technische Hochschule, Zürich). *Institute of Metals, Advance Copy* No. 585, Sept. 1931, 13 pages.
Laboratory corrosion tests indicated that Duralumin could be quenched in either water or oil at 50° C. and aged at this temperature without decreasing its corrosion resistance. After aging at 145° C., however, the corrosion resistance is very low. Sheets quenched in warm water or oil do not warp as much as those quenched in cold water. The difference in corrosion resistance of Duralumin treated in various manners can be explained by differences in potential produced. Bibliography of 6 references. JLG (4)

Common Method for Testing Corrosion. Harry F. Perkins (St. Louis Surfacer & Paint Co.) *Oil & Gas Journal*, Vol. 29, Sept. 18, 1930, pages 39, 74.
The author gives the following directions for testing corrosion each item of which he discusses in detail: Select materials that can be conveniently manufactured and that can be used conveniently in the service under consideration. The specific gravity of the metal under test must be known. A check sample of steel or other metal commonly used should always be employed. (1) Clean surface of all scale and foreign material. (2) Measure all exposed surface accurately in square centimeters. (3) Weigh to fourth decimal point in grams. (4) Suspend or support in corrosive medium at a point where the corrosive action will be as near as possible to that of actual service. (5) Insulate samples electrically and maintain a clear spacing of 1 in. (6) Remove samples periodically (once a mo.) wash off mud, oil and loosely adhering corrosion products using as little force as possible. Dry quickly. (7) When dry weigh carefully and examine for pits and scale. (8) Replace in test. (9) Final weighing should be made after every trace of corrosion products has been removed. Data in the form of a chart is given on several metals exposed to oil vapors and moisture. VVK (4)

The Use of Phosphate in Boiler Water Conditioning. F. J. Matthews. *World Power*, Vol. 16, Oct. 1931, pages 307-312.
Discusses the treatment of boiler water to prevent corrosion and scale formation. The general conclusion is that in order to prevent adherent scale formation on boiler heating surfaces, it is only necessary to adjust the ratio of the requisite acidic ions so that throughout the whole period of evaporation the solubility products of substances of positive temperature coefficients will always be reached before the solubility products of substances with negative temperature coefficients. Data shows that phosphate conditioning is quite satisfactory for a boiler operating as high as 1300 lbs. pressure. WAT (4)

Chrome Iron Indispensable in Nitric-Acid Plant. E. St. P. Bellinger (Hercules Powder Co.). *Chemical & Metallurgical Engineering,* Vol. 37, Nov. 1930, pages 691-692.

Addition of Cr to a low-C steel increases the resistance to corrosion by HNO_3, the resistance increases very rapidly between 13-18% Cr, beyond 18%, the effect of Cr is slight. More than 0.12% C or 1% Si lessens the resistance to corrosion. Small amount of Si is essential, however. Heat treatment is an important factor in determining rate of corrosion. Prolonged annealing at 1450° F. is generally considered the best heat treatment. Metal becomes hard and brittle, accompanied by reduced corrosion resistance when heated for long periods at 600°-800° F. or to temperatures above 1700° F. followed by air cooling. Re-annealing restores the original qualities. In general, cast material has higher rate of corrosion than worked. Subjection of properly annealed and worked material to heat, shock and strain does not appreciably increase rate of corrosion. Metal can be worked safely at 1000°-1400° F. Presents results of tests in a table and by means of curves. MS (4)

The Constitution of Scale. L. B. Pfeil. *Engineer,* Vol. 151, May 15, 1931, page 536.

Abstract of paper read before the Iron & Steel Institute, May 7-8, 1931. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 248. LFM (4)

Cadmium and Zinc Plating as Rust Preventives. *Brass World,* Vol. 27, Aug., 1931, pages 171-175.

An article based on a paper given before the Electroplaters' & Depositors Technical Society in London. Comparison is made of deposits of the 2 metals as to corrosion resistance, acid resistance, and color. Strong acids attack Zn more readily than Cd while after removing the coating corrosion of the underlying ferrous metal appears to be slower with Cd than with Zn. Alkalies attack Zn more readily, but also discolor Cd. WHB (4)

Pipe Line Corrosion and Soil Conductivity. *Engineering News Record,* Vol. 107, July 23, 1931, page 135.

Observations made by the Bureau of Standards, of corrosion, electric current and soil conditions on 9 pipe lines, led to the conclusion of a definite correlation between pipe corrosion and soil resistivity. Where soil conductivity is high, corrosion occurs. A method of measuring soil resistivity with 2 oak rods tipped with iron, one carrying a small flash light battery and the other, a milliammeter with 100 milliampere scale. The rods are pushed down into the ground about 8 ins. apart. The soil resistivity was measured along pipe lines and all stretches in which the soil was abnormally conductive were found to be regions of corrosion trouble and, generally, of current departure. The soil resistivity at such places was usually below 500 or 600 ohms/cm.^{3} With higher resistivities, no marked corrosion was found. Ha (4)

Rust Preventive Agents. *Chemical Age,* London, Vol. 23, Metallurgical Section, Nov. 1, 1930, page 28.

2 new rust preventive agents have been reported by the German Mannesmann Tube Works. Herolith is a synthetic resin and is applied by brushing, prior to which scale is removed by pickling. Tubes coated with it have successfully withstood thorough mechanical and chemical tests; the former comprises tests for resistance to shock, scratching and conveyance by train or motor. 35 corrosive agents were used in the chemical tests, only 3 of which (hydrofluoric acid, caustic potash solution and caustic soda solution) had any effect on the tubes. Dry heat up to 220° C. and intermittent temperatures up to 300° C. do not injure the coating. Tornesit is a rubber product similar in appearance to cellulose. It can be brushed on the part to be protected without preheating being necessary and dries in 3 minutes. It hardens to such an extent after a few hours that even heavy hammer blows do not damage the coating. In contrast to herolith, tornesit is resistant to alkalies and is only attacked by hydrogen sulphide, water, benzol, acetone and aniline. It can be employed as a protective coating for iron and steel, wood, brickwork and concrete. No original data is given. VVK (4)

Copper Steel and the Mechanism of its Resistance to Corrosion (L 'acier au cuivre et le mécanisme de sa résistance à la corrosion). *Cuivre et Laiton,* Vol. 4, Nov. 15, 1931, pages 495-498.

As the theory developed by Carius (*Zeitschrift für Metallkunde,* Oct., 1930, Nov., 1930, see *Metals & Alloys,* Vol. 2, July, 1931, page 127) on the corrosion of copper steels does not furnish entirely satisfactory explanations, the phenomenon is discussed here with some modifications and the discrepancies with facts are noted. The action of atmosphere first forms a layer of rust under which, after some time, a layer of copper oxide appears; this layer is impermeable and stops the further progress of oxidation of the steel. The copper oxide is the result of a thin film of copper which has formed on the steel. A section through the steel thus reveals a thin layer of copper on the steel on which a layer of copper oxide is formed. Similar conditions occur in the attack by distilled water. Salt solutions have a more complex effect. A section through the steel shows first a thin layer of powdery copper on the steel, then a film of green ferrous hydroxide, on which a layer of ferro-ferric hydroxide is found and, finally, the outer layer formed of a red-brown ferric hydroxide. The formation of these different layers is explained by the high oxidation potential in saline solutions. In acid solutions, copper steel is particularly resistant because the copper layer on the steel is especially compact and dense here and offers a very good protection against further corrosion. Ha (4)

Protection of Iron Containers Against Acids by Lead Lining by the Oxy-Acetylene Flame (Säureschutz für Eisenbehälter durch Verbleiung mittels Azetylen-Sauerstoff-Flamme). *Schmelzschweissung,* Vol. 10, Aug. 1931, pages 202-203.

In order to obtain a firm adhesion of the Pb lining to the walls of the tank, these walls are first coated with a solder of an alloy of Sn and Pb in equal parts and which combines well with the tank material and the Pb. The method is described and illustrated. Ha (4)

STRUCTURE OF METALS AND ALLOYS (5)

Laws Governing the Segregation of Minute Quantities of Matter in the Case of Solid Solution Formation (Ueber die Gesetzmässigkeiten bei der Abscheidung kleinster Substanzmengen unter Mischkristallbildung). R. Mumbrauer (Kaiser Wilhelm Institut für Chemie, Berlin-Dahlem). *Zeitschrift für physikalische Chemie,* Sect. A, Vol. 156, Sept. 1931, pages 113-134.

The experiments aim at a clear conception of the mechanism dominating the distribution of minute quantities of matter between a solid and liquid phase, in the case that solid solutions are formed. The way of distribution of the microscopic component within the system of solid solutions in relation to the working conditions is furthermore systematically studied. A hypothesis concerning the mechanism of segregation is evolved from the observations made. EF (5)

Metallography and Macrography (5a)

Alloys of Iron, Manganese and Carbon. Part I. Preparation of Alloys. Francis M. Walters, Jr., *Mining & Metallurgical Investigations Bulletin* 101, 1931, pages 1-13.

Because of the importance of Mn as an alloying element, a systematic study of this tenary system was undertaken. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 283. Ha (5a)

Alloys of Iron, Manganese and Carbon. Part II. Thermal Analysis of the Binary Alloys. Francis M. Walters, Jr. & Cyrill Wells. *Mining & Metallurgical Investigations Bulletin 101,* 1931, pages 14-22.

The thermal analysis was made on alloys of high purity of Fe-Mn with from 0 to 60% Mn in a modified gradient furnace of Rosenhain. The results agree in general with those of previous investigators. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 283. Ha (5a)

Alloys of Iron-Manganese and Carbon. Part IV. A Dilatometric Study of Iron-Manganese Binary Alloys. F. M. Walters, Jr. & M. Gensamer. *Mining & Metallurgical Investigations Bulletin* 101, 1931, pages 32-45.

In these studies, a dilatometer was used in which the specimen can be tested at temperatures from — 200° to 1000° C. in a vacuum or an inert gas. The indications of phase changes observed by thermal analysis have been confirmed and extended. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 283. Ha (5a)

Magnetic Properties Versus Allotropic Transformations of Iron Alloys. T. D. Yensen & N. A. Ziegler (Westinghouse Electric & Mfg. Co.) *American Institute of Mining & Metallurgical Engineers, Technical Publications* No. 427, Sept. 1931, 7 pages.

Elements that increase γ field adversely affect the magnetic properties of Fe, while, in general, those that tend to close the γ loop have a beneficial effect. The latter group of elements tends to distort the Fe lattice less than elements of the former group. The elements that increase the permeability of Fe do so because they precipitate harmful elements from solution. 15 references. JLG (5a)

The Surface Energy of Iron Carbide. Yap, Chu-Phay. *American Society for Steel Treating, Pre-print* No. 10, 1931, 24 pages.

Paper read and discussed before the Boston Convention of the Society in Sept. 1931. 13 references to the literature are cited. The author presents a theory that the hardness of steel is accounted for by the surface energy of iron carbide. The particle size of Fe_3C dispersed in martensite is of the order of 3 to 4 times 10^{-7} cm. in radius. A physico-chemical picture of the role of surface energy in the hardening of alloys is presented. WLC (5a)

Lead-Thallium Alloys. R. R. Rogers. *Mining & Metallurgy,* Vol. 12, Feb. 1931, pages 96-97.

The existence of a compound, $PbTl_2$ has been confirmed. Solid solutions of $PbTl_2$ in lead exist between O and 67% Tl. Pb-Tl alloys possess good corrosion resistance and compressive strength, particularly with additions of Sn, Bi and Ba. Tl in lead has practically no effect on the passivity of the anode from 0.5 to 2.0%, but beyond this concentration, a decided effect in the lowering of the Pb in the cathode Zn takes place. Ha (5a)

Deep Etch is Valuable Tool to Brass Foundrymen. R. W. Parsons. *Foundry,* Vol. 59, June 1, 1931, pages 51-53.

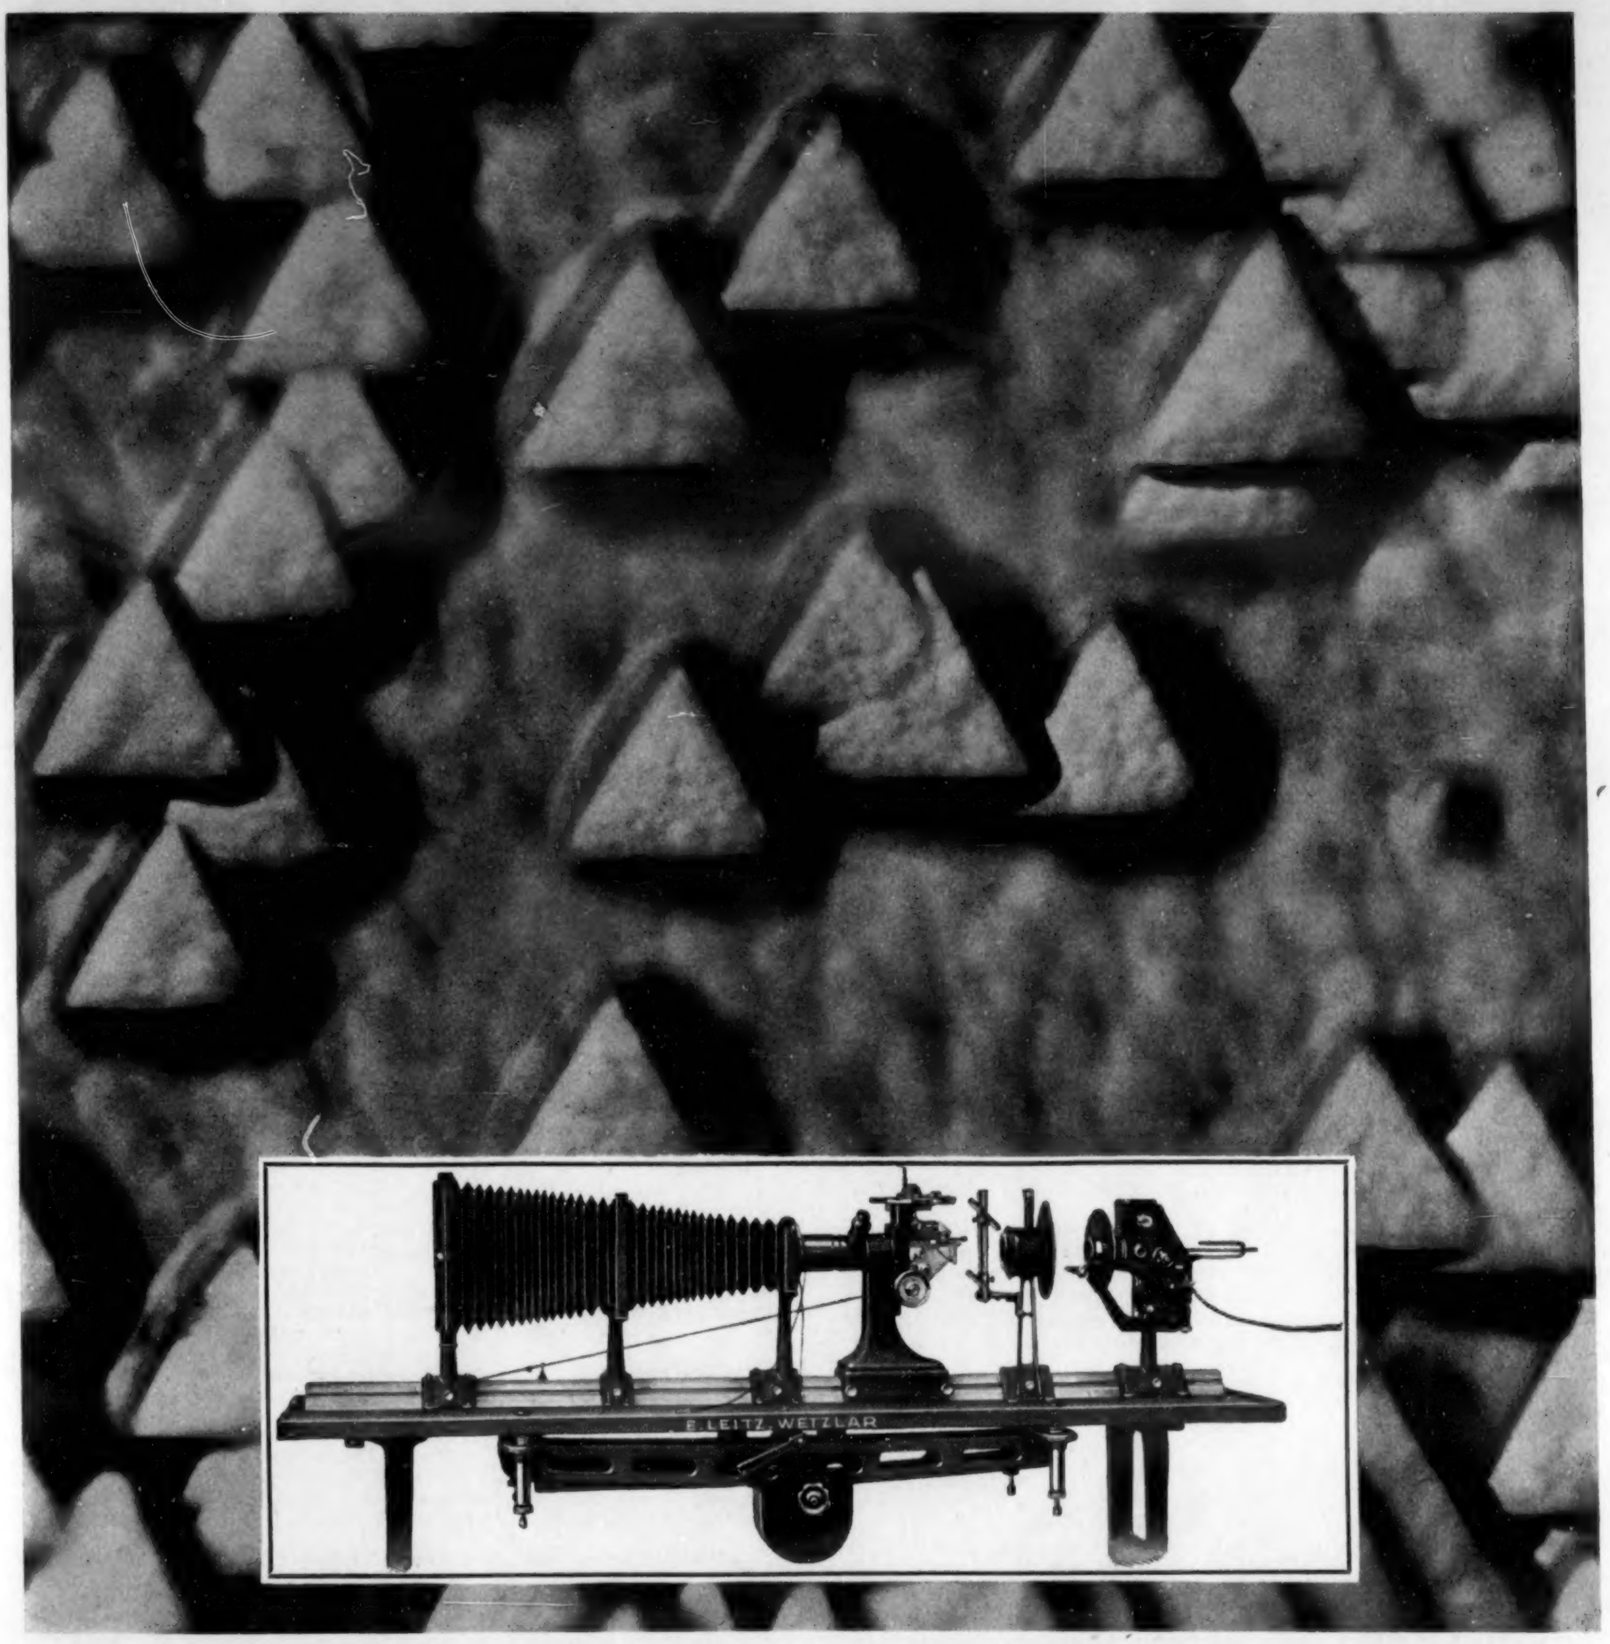
Deep etching of brass is accomplished by subjecting the specimen to the action of concentrated commercial nitric acid for a period of 7-8 min. Although this method is very valuable in detecting defects, limitations must be placed on the application of the test to red brass in general. It is explained that it is practically impossible to draw any conclusions with regard to metal conditions from etched sections of dissimilar castings because gating plays a very important part in determining the quality of the casting. The results of the etch test and the method of gating should be studied for similar castings to find improvements for the quality of the castings. Several examples illustrate the method. Ha (5a)

The Microscope for Production Control in the Small Plant. G. E. Shoemaker. *Iron Age,* Vol. 128, Oct. 29, 1931, pages 1100-1104.

The author explains and describes the advantages and possibilities of laboratory control of production by showing micrographs and macrographs of good and of defective metal specimens. He gives a layout of a little laboratory for simple metallurgical and chemical tests. Ha (5a)

Illumination of Metallurgical Specimens. Conrad Beck. *Journal Royal Microscopical Society,* Vol. 50, Sept. 1930, pages 319-322.

For vertical illumination, the prism reflector is satisfactory with low powers, but with high powers the loss of aperture, and hence of resolution, is considerable. The correct use of the transparent reflector is described, the essentials being centration of the light, complete illumination of the objective, and focussing of the light on the specimen. The question of glare is discussed and Wrighton's method for its elimination is described. It is suggested that ultraviolet illumination may not be of much value in metallurgy, as the reflective power of metals is less for ultra-violet than for visible light, and trouble due to glare is therefore accentuated. Ha (5a)



The Basic Structure of "X-ITE" - 7200X-Nickel-Chromium Alloy - Conical oblique illumination-Magnetic arc lamp - Apo. Oil Im. 2 mm, N. A. 1.32, - Per. Ocular 8X Wr. "B" filter - Wr. "M" plate - 1. min. exposure - CHG method sample preparation. Taken with LEITZ "MM."

The Final Authority In Metal Analysis . . .

No single detail of construction in your sample escapes the sharp eye of the LEITZ MICRO-METALLOGRAPH. This precision instrument supplies you with an absolutely accurate photographic analysis of your product, taking the place of guess work and inconclusive testing . . . The LEITZ MICRO-METALLOGRAPH is operated quickly and easily. Its scientific construction guarantees immunity against external vibrations in the laboratory. It provides absolute flatness of field over the entire photographic plate (including size 8" x 10"). And its equipment includes the greatest assortment of objectives and eyepieces to meet whatever requirements may arise.

The LEITZ METALLOGRAPH is the accepted standard because it bears the name of the world's foremost maker of precision optical instruments. That fact alone means that the most skillful workmanship has gone into the manufacture of the instrument and that its optical equipment is the last word in perfection and dependability.

LEITZ MICRO-METALLOGRAPH

The Brass Foundry in America; the Deep Etching Test for Brass (La fonderie de Laiton, en Amerique. L'essai d'attaque profonde du laiton). *Cuivre et Laiton*, Vol. 4, Sept. 15, 1931, pages 406-411.

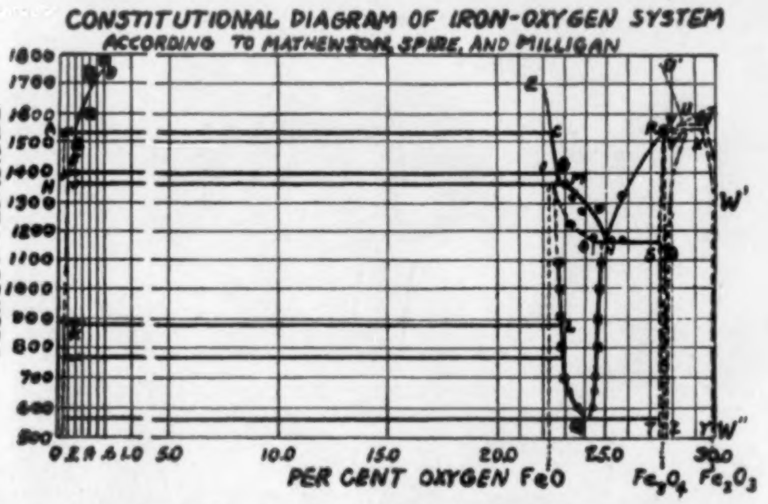
The deep etching test has been very well developed for ferrous materials, but not for non-ferrous metals. The author reviews American methods for utilizing this method of deep etching on the surface for macrographic examination and advises their use for the supervision of the furnaces. Several examples are illustrated. Ha (5a)

A Study of the Constitution of the Iron-Tin Alloys. C. A. Edwards & A. Preece. *Engineer*, Vol. 152, Oct. 2, 1931, page 347; *Iron & Coal Trades Review*, Vol. 123, Oct. 2, 1931, page 495.

Abstract of a paper read before the Iron & Steel Institute, Swansea, Sept. 1931. See *Metals & Alloys*, Vol. 2, Dec. 1931, page 302. LFM+Ha (5a)

Evolution of the Iron-Oxygen Constitutional Diagram. C. H. Mathewson, E. Spire & W. E. Milligan (Yale University). *Transactions American Society for Steel Treating*, Vol. 19, Nov. 1931, pages 66-88; *Metal Progress*, Vol. 19, Apr. 1931, page 83.

Doctor's thesis of E. Spire. 29 references to the literature. 12 micrographs show structures described. The authors discuss previous reports on the iron-oxygen diagram. Considerable consideration is given to the equilibrium between oxide phase and iron containing oxide in the liquid state



and cooled. Oxygen appears to widen the range of stability of the γ phase in iron, in which it is more soluble. The region of the diagram representing equilibrium between ferrous and ferric oxides has been studied by thermal and microscopic methods. A diagram is constructed in the light of the work of previous investigators and the findings of the authors. The oxide particles found in iron may be either ferrous or combined ferrous-ferric according to the thermal treatment. WLC (5a)

Microstructure of Pearlite. H. E. Publow & C. Heath (Michigan State College). *Metals & Alloys*, Vol. 2, Sept, 1931, pages 155-157.

The authors discuss, with 12 micrographs illustrating their study, the mechanism of the recrystallization of austenite as it cools through the critical ranges. The micros are of low C steel, to which the discussion applies. WLC. (5a)

Diffusion in Metals (Diffusion in Metallen). G. von Hevesy & W. Seith. *Zeitschrift für Elektrochemie*, Vol. 37, Aug.-Sept. 1931, pages 528-531.

The diffusion of a metal in another solid metal is, in most cases, a practically one-sided phenomenon. The diffusion velocity of Au in Pb is a very fast one, while that of Pb into Au is very slow. With increasing similarity of the 2 constituents of an alloy, for instance for the transition Au-Pb, Ag-Pb, Bi-Pb, Tl-Pb, Pb-Pb, the one-sidedness of the phenomenon disappears gradually. At the same time, the activation heat of the faster diffusing constituent is increased. Measurements of diffusion permit the determination of even very small solubilities of one metal in another, e. g., the solubility or Ag in Pb was found at 285° C. to be 0.13 atomic %. 7 references. Transformations in Light Aluminum Alloys in Accordance with their Structure. G. A. Kaschtchenko. *Transactions of the Second Conference of Non-Ferrous Metals of U. S. S. R.*, 1927, pages 326-358.

Heat-treated alloys containing 1.5, 3.0, 5.0, 7.0 and 12% Cu and also 1.2, 2.5, 5.0, 10 and 20% Mg have been examined. In order to attain uniformity, all the specimens were etched simultaneously. It was shown that the aging of light Al alloys must be ascribed to the separation of $CuAl_2$ from the solid solutions. The addition of Mg causes an increase in hardness due to a solid solution with Al, but has no influence on the aging process as a whole. Although it assists the disintegration of the solid solution, permitting the separation of $CuAl_2$ at a lower temperature, magnesium silicide has no influence on the aging process, being present in negligible quantities, and the effect ascribed to it is due to the separation of $CuAl_2$ at a lower temperature owing to the presence of Mg. (5a)

Decomposition Structures of Copper-Zinc Alloys and Copper-Aluminum Alloys. Robert F. Mehl & C. T. Marzke. *Rolling Mill Journal*, Vol. 5, Mar. 1931, page 219.

Abstract of a paper presented at the New York Meeting of the American Institute of Mining and Metallurgical Engineers, week of Feb. 16, 1931. See *Metals & Alloys*, Vol. 2, June, 1931, page 111. JN (5a)

Arrangement of Micro-Crystals in Rolled Foils of Tungsten and Molybdenum. *Proceedings World Engineering Congress, Tokyo*, 1929, published 1931, Vol. 36, *Mining & Metallurgy*, Part 4, pages 179-182.

Metallographers' Handbook of Etching. Torkel Berglund. Translated from the Swedish by W. H. Dearden. Isaac Pitman & Sons, London & New York, 1931. Cloth, 5½ x 8½ inches, 183 pages including bibliography and index. Price $3.75.

This book, sponsored by the Swedish Society of Metallographers, will be a boon to all practitioners of the art, most of whom it is safe to say have been privately collecting lists of etching reagents. The compilation of ferrous and non-ferrous etchants is much more extensive than those heretofore published by such agencies as the American Society for Testing Materials, the American Society for Steel Treating, and the Verein Deutscher Eisenhüttenleute. Moreover, the book is more than a mere handbook. The originality of the treatment of the technique and rationale of metallographic etching together with numerous notes on experience with various etchants justify classing the work as a real contribution to metallographic knowledge. The book is clear and easy to read. The scarcity of illustrations may perhaps detract from its usefulness for the beginner, but the well versed metallographer will hardly regret this lack. There is a good index.

Under the heading Chemistry of Etching a very lucid explanation, greatly aided by the ionic notation in vogue in electrochemical texts, is given of the chemical action of the various groups of etchants. The technique of etching electrolytically, by heat tinting, and in vacuum is described as well as the less well known method of etching with gelatine films in which etching media have been impregnated. This is covered in considerable detail although the gelatine method of detecting pin holes in tin plate is omitted. The subject of revealing fine cracks is also embraced, although it is not dealt with very extensively. Etching by cathodic sputtering is briefly mentioned.

After a general discussion of macro-etching, a detailed account is given of the composition and action of the various copper bearing agents, including Fry's reagent for revealing strain lines. Among these numerous reagents only d'Huart's reagent, similar to Fry's, has apparently escaped the author's attention. Koster's results and those of his German colleagues on the relation between the N content of a steel and its response to strain line etching probably appeared too late for inclusion in the book.

For micro-etching of steel the author recommends a 4% solution of nitric acid in amyl alcohol. The alkaline reagents for carbides in plain C and alloy steel, especially high speed steel, are handled at length and adequately. The treatment of etchants for nitrides is on the other hand very brief, the newer copper bearing reagents receiving no mention. The etching of stainless steel is well covered, the indispensable precaution of repeated etching and polishing of the soft austenitic type being emphasized. There is an extremely interesting account of the etchants for sulphides in steel in which the gelatine technique has a prominent place. In dealing with the etching and identification of inclusions in steel in general, the author has relied mainly on the work of Campbell and Comstock and of Wohrman.

Non-ferrous etchants are dealt with more briefly, this section comprising only one-fifth of the book. However, the etching of Al, particularly, and Cu, and Ni and their alloys is very adequately treated, although no attempt is made to recommend solutions for special alloys. For example, one desiring to etch speculum metal (70% Cu, 30% Sn) would have to use his own judgment in selecting an etchant from among several given for Cu and its alloys. No mention is made of etching reagents for the noble metals or alloys in use as jewelry and as dental alloys.

Some Physico-Chemical Modifications of So-Called Pearlitic Iron (Sur quelques modifications physico-chemiques des fontes dites perlitiques). A. Le Thomas. *Congrés International des Mines, de la Métallurgie et de la Géologie appliquée Section de Métallurgie*, 6th session, Liege, June 1930, pages 831-852. 32 figures.

Includes discussion on this and other papers on high-strength cast iron presented at the same session. See *Metals & Alloys*, Vol. 2, Nov., 1931, page 250. HWG (5a)

Nickel-Chromium and Iron-Nickel-Chromium Alloys. *Metallurgist*, Sept. 1931, pages 134-136.

A brief résumé of the subject presenting the most recently developed constitutional diagrams. WAT (5a)

The Formation of Ferrite from Austenite. H. C. H. Carpenter & J. M. Robertson. *Iron & Steel Industry & British Foundryman*, Vol. 4, May 1931, pages 273-275.

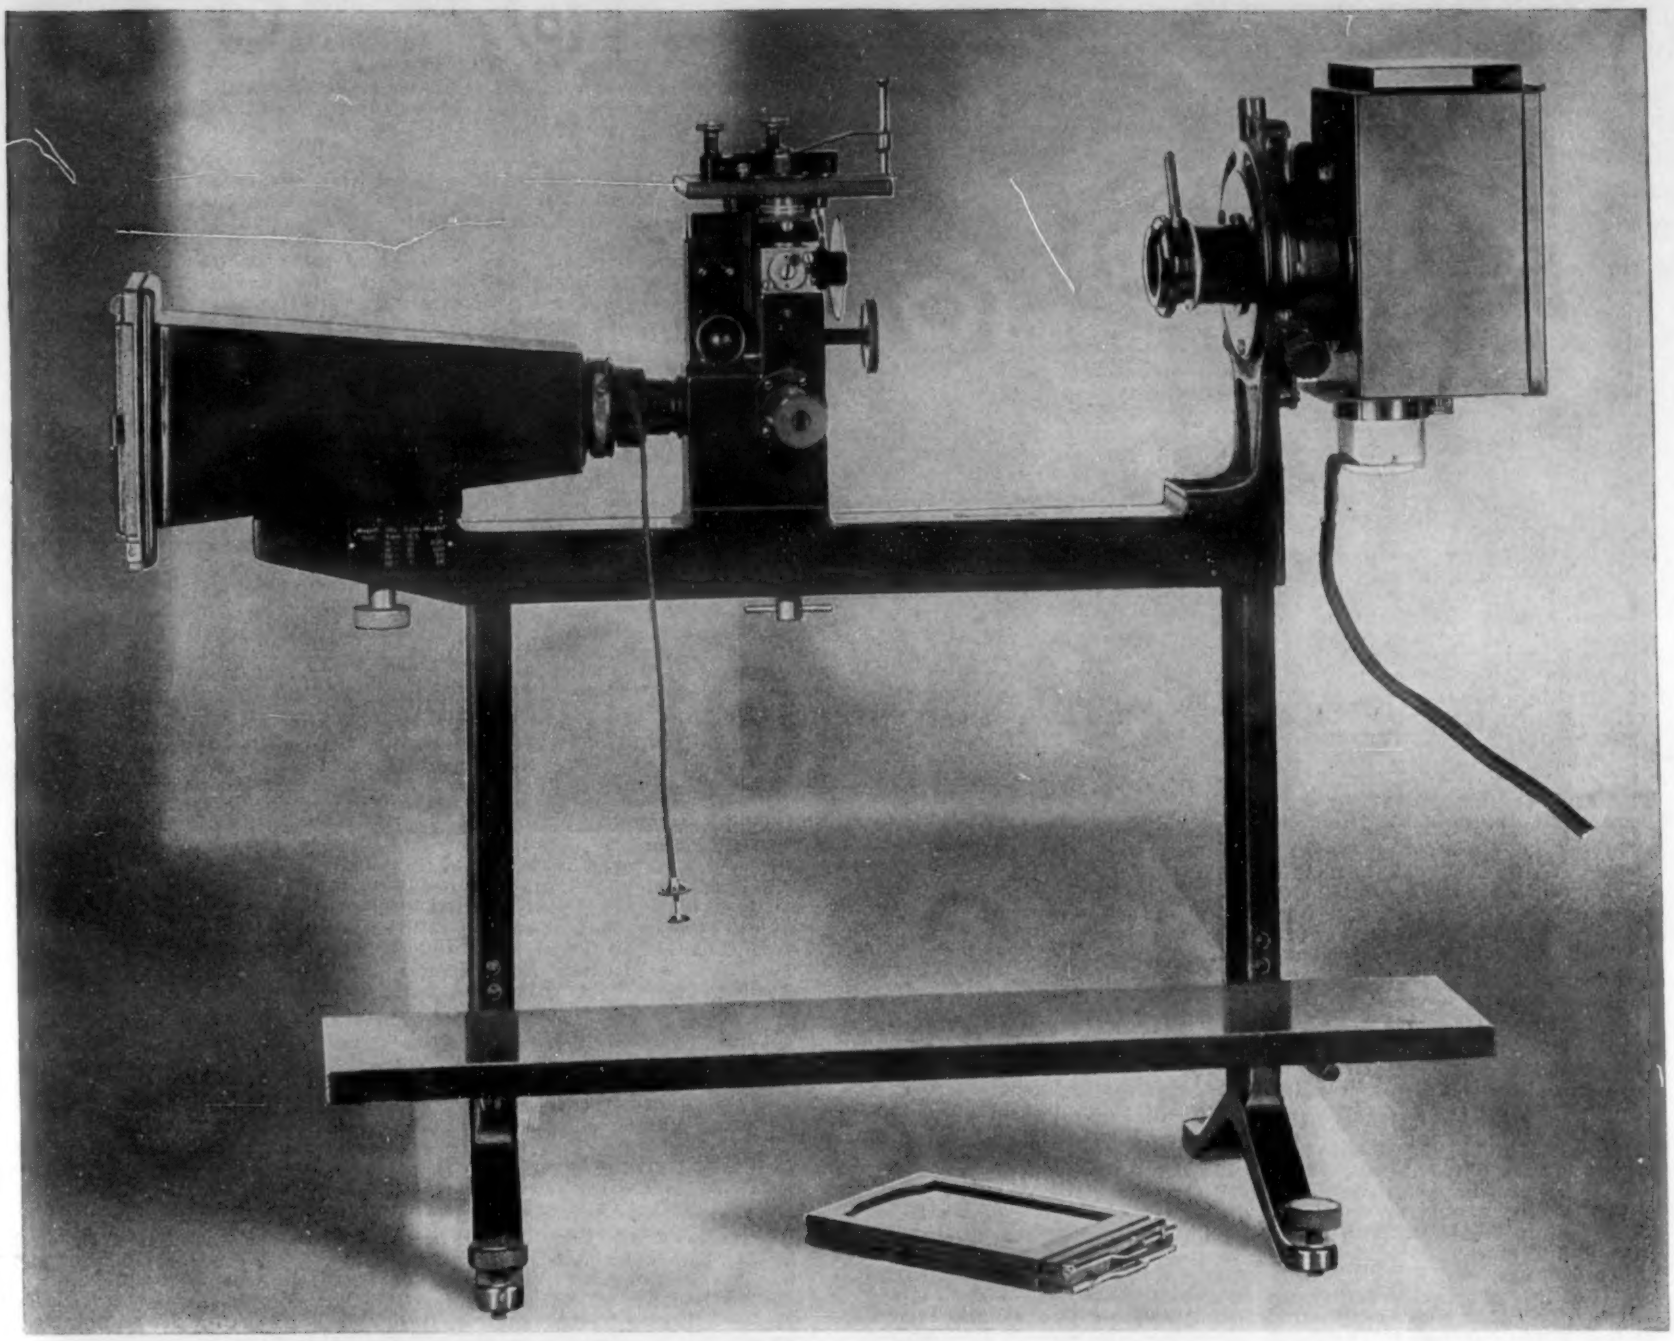
The different ferrite-pearlite structures produced from grains of austenite as affected by the C content and rate of cooling of steel were studied. A theory to explain the structural changes is advanced. See *Metals & Alloys*. Vol. 2, Nov. 1931, page 252. CHL (5a)

The Sub-Crystalline Structure of Ferrite. C. O. Bannister & W. D. Jones. *Iron & Steel Industry & British Foundryman*, Vol. 4, June 1931, pages 297-298.

Abstract from Iron & Steel Institute paper. See *Metals & Alloys*, Vol. 2, Nov. 1931, page 250. CHL (5a)

Practical Methods for Study and Control of Cast Iron, New Metallographic Procedure for Graphite (Méthodes simples et pratiques pour l'etude de la fonte de fer et le controle de la fabrication des moulages, nouveau procédé de métallographie du graphite). L. F. C. Girardet. *Congrés International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 854-861. 16 references, 18 figures.

Treats with effect of graphite, with various methods of testing, including shear, which the author characterizes as the best mechanical test for cast iron, and with metallographic examination. He suggests study of graphite after etching with 25 cc. HCl, 100 cc. H_2O, 10 g. CrO_3, 5 grams anhydrous $NiCl_2$. This etchant is claimed to show up the size and shape of the graphite particles more clearly than the examination of an unetched surface. HWG (5a)



Recent Progress in Japan in the Field of the Science of Metals. *Proceedings World Engineering Congress,* Tokyo, 1929, published 1931, Vol. 36, *Mining & Metallurgy,* Part 4, pages 7-60. In English.

Lists and briefly comments on 182 papers by Japanese metallurgists and reproduces many equilibrium diagrams determined or re-determined by them. Honda's ideas on the hardening of steel are given special mention. HWG (5a)

Strain Etching Figures. *Metallurgist,* Feb. 1931, pages 19-21. An extended critical review of the second part of Köster's paper ("The Problem of Nitrogen in Mild Steel," *Archiv für Eisenhüttenwesen,* Apr., 1930, page 637). Flow figures or Lüder lines appear at the beginning of the plastic deformation of a slowly cooled low carbon steel. They are patterns which are formed by the roughening of the smooth surface of the steel and, in the case of a rolled material, become visible by the breaking away of the oxide layer. They are said to be due to local deformation; the deformed portions are pushed up against the undeformed regions. They are found particularly in material in the aged condition. Fry's reagent is used for bringing out these strain etching figures. Nitride layers are strongly darkened by this reagent and steels which do not age magnetically, i. e., in which nitride does not separate out, show no strain etching figures.

In plastically deformed steel containing N, from Köster's experiments, the degree in which the deformed region is made visible by Fry's reagent is proportional to the quantity of N in supersaturated solution. By further experiments, he showed that the separation of nitride is accelerated by cold deformation and the strain figures are produced by the contrast between this separation in the deformed and undeformed regions. This was confirmed by a microscopic investigation of the structure. The precipitation of nitride proceeds more quickly in the undeformed region. After heating to higher temperatures, however, strain figures are still produced and it was shown that the deformed material retains its properties, even after heating to the higher temperature, unless recrystallization takes place. The appearance of strain figures after heating to such temperatures depends on the rate of cooling. VVK (5a)

Intimate Chats on Metallography. VIII. *Nickel Cast Iron News,* Vol. 2, Aug. 1931, pages 5, 11.

The control of C contents in blast furnace and cupola is explained. The Fe-C equilibrium diagram for cast iron is discussed and a glossary of technical terms, used in connection with the metallography of Fe, are given. Ha (5a)

The Phosphide Eutectic in Cast Iron. *Metallurgist,* Jan. 1931, pages 5-6.

Phosphorus in cast iron usually makes its appearance as a ternary phosphide eutectic, known to some as "Steadite," the melting point of which is in the region of 950° C. Künkele and Bardenheuer & Künkele (*Mitteilungen aus dem Kaiser Wilhelm Institut für Eisenforschung,* Vol. 12, 1930, pages 145-146) have investigated the Fe-P system with the following conclusions. The Fe-P-C alloys may solidify as a metastable system iron-iron carbide- iron phosphide or as a stable system iron-graphite- iron phosphide. In the first case, by exceeding the solubility of the C and P in the iron, the alloys form the ternary phosphide eutectic, of which the constituents are ternary solid solution, iron carbide and iron phosphide. In the second case, a ternary eutectic is formed, involving ternary solid solution, graphite and iron phosphide. Here, however, the graphite crystallizes on the already existing graphite flakes, and for this reason seems to disappear from the eutectic. In reference to this fact, such a ternary eutectic has been termed "pseudo-binary." Gray cast irons may, nevertheless, exhibit a normal ternary phosphide eutectic containing cementite when cooling conditions have favored solidification, at first according to the stable system and later according to the metastable system. The results of thermal analysis and quenching experiments which are given confirm this view. In the second paper, it is shown that raising the Mn content from about 0.15% to about 0.7% has practically no influence on the type of phosphide eutectic formed. The usual method of etching Fe-C-P alloys, including that of heat tinting, resulted in the colors becoming frequently blurred and the presence of other elements such as Mn and Si, seemed to increase this tendency. It was found that a boiling aqueous solution containing 5 to 8% chromic acid slightly roughened the surface of iron phosphide, and that a higher contrast between this constituent and iron carbide could then be developed by heat tinting. VVK (5a)

The Chromium-Iron Equilibrium Diagram. *Metallurgist,* Sept. 1931, pages 139-140.

A brief résumé of the subject presenting a constitutional diagram. WAT (5a)

The Electrical Conductivity and the Thermal Expansion of Magnesium-Cadmium Alloys (Die elektrische Leitfähigkeit und die thermische Ausdehnung der Magnesium-Kadmium-Legierungen). G. Grube & E. Schiedt. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 194, Dec. 9, 1930, pages 190-222.

The conversions in the solid state occurring in the Mg-Cd system at temperatures below 300° C. were explained by measurements of the change of the resistivity and the length as functions of the temperature. This was done with alloys containing 20-80% (atomic) of Mg which had been carefully annealed and subsequently cooled very slowly. From the curves so obtained, the following conditions of constitution can be stated: at temperatures above 250° C., 2 series of solid solutions exist, α and β, which are separated by a gap between 28-30 atomic % of Mg; at 89° C., the α-solid solution is transformed with 25% Mg into the compound $MgCd_3$; at 250° C. and 150° C., respectively, the β-solid solutions are transformed with 50% and 75% Mg into the compounds MgCd and Mg_3Cd, respectively. These 3 compounds again form solid solutions among themselves and with the components. The gap at 28% to 33% disappears below 120° C. The form of the resistance-temperature curves and the curves of thermal expansion for the ranges 40-60 atomic % and 70-80 atomic % Mg indicate that here the conversion from compound into solid solution takes place in 2 stages. The Magic of Modern Industry; Locating Defects and Causes of Defects by Means of the Radiograph—Determining the Hardness of Metals through Crystal Orientation. Ph. Winter. *Modern Machine Shop,* Vol. 4, Oct. 1931, pages 11-14, 16, 85.

Description of X-ray outfits, illustrations of defects in materials photographed by them, and the possibility of following the processes of manufacturing by diffraction patterns. Ha (5b)

Alloys of Iron, Manganese and Carbon. Part III. An X-Ray Study of the Binary Iron-Manganese Alloys. M. Gensamer, John F. Eckel & F. M. Walters, Jr. *Mining & Metallurgical Investigations Bulletin* 101, 1931, pages 23-31.

A systematic X-ray investigation of low C Fe-Mn alloys by the Debye-Hull method confirms, in general, the work of Schmidt and of Oehman. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 283. Ha (5b)

Alloys of Iron, Manganese and Carbon. Part III. An X-Ray Study of the Binary Iron-Manganese Alloys. M. Gensamer, John F. Eckel & F. M. Walters, Jr. *American Society for Steel Treating,* Preprint No. 35, 1931, pages 23-45.

A systematic X-ray study of low carbon Fe-Mn alloys confirms the general work of Schmidt and Ohman. It was found that cold work favors the formation of the hexagonal closepacked phase which is also present in some alloys on quenching but is absent from slowly cooled alloys. 11 references. WLC (5b)

Radiographic Inspection with Gamma Rays. R. F. Mehl. *American Machinist,* Vol. 75, Aug. 13, 1931, pages 278-280.

The inspection of large finished pieces by X-ray is often impossible because of the cumbersome apparatus required. The Naval Research Laboratory, therefore, made some tests with radium. The γ-rays emitted from it have a much shorter wave length (about 1×10^{-10} cm.) and the time of exposure can, therefore, be reduced. The radium is either held in a small capsule or radium emanation, a gas which radium generates spontaneously, is enclosed in a glass and metal capsule. Either can be used with equal effectiveness. The method is shown on a large irregular casting where the radium could be brought to any desired place. This had not been possible with X-rays. Ha (5b)

Iron, Carbon, Nitrogen Structural Analogies Revealed by X-Rays. A. Westgren. *Metal Progress,* Vol. 20, July 1931, pages 50-54.

The author reports X-ray studies of iron-carbon-nitrogen system giving the cell characteristics and dimensions, of various phases. The effect of nitrogen is discussed. Nitrogen equilibrium diagram shown and the relation of these results to nitriding research discussed. Absorption of nitrogen in austenite is shown. WLC (5b)

Progress in the X-Raying of Iron (Fortschritt in der Röntgendurchstrahlung von Eisen). M. Widemann. *Giesserei mit Giesserei-Zeitung,* Vol. 18, July 17, 1931, pages 576-580.

The factors affecting the further progress in testing with X-rays large metal pieces, especially of iron, are discussed in detail. X-ray tubes should be developed to stand a continuous operation with considerably more than 200 KV, as are now available. The equipment of the iron-metallurgical Institute of the Technical University, Berlin, is described and the methods usually applied are described. Exposing times for cast iron in milli-ampere seconds as a function of the thickness of the iron are determined and also as a function of the voltage. A few formulas are developed for calculating the time required for a given thickness of material and blackening effect of the film. Ha (5b)

X-Ray Investigation of Lattice Disturbances in Light Metals (Röntgenographische Untersuchungen von Gitterstörungen in Leichtmetallen). J. Hengstenberg & H. Mark. *Zeitschrift für Elektrochemie,* Vol. 37, Aug.-Sept. 1931, pages 524-528.

The object was to find whether the great increase in strength of duralumin and electron metal after refining could be proved by measuring the changes of the position of the atoms. It is assumed that a certain number of atoms are shifted somewhat from their normal position by deformation of the material. They are therefore not in phase with the other atoms of the lattice and reduce the intensity of the reflection of an X-ray; the greater the shift from the normal position, the greater is the reduction in intensity of reflection. This reduction in intensity could be verified in the tests. 6 references. Ha (5b)

Radiographic Inspection of Materials. H. R. Isenburger. *Mechanical Engineering,* Vol. 53, Oct. 1931, pages 729-735.

The relative value and application of X-rays and γ-rays for the inspection of metals are discussed. The X-rays are used for industrial purposes. The equipment is described and the various defects of castings and welds are demonstrated and explained by means of photographs. For very heavy material of more than 3 ins. thickness, γ-rays should be used because they are more penetrating. They also give finer details in thinner materials. The operating cost with X-rays amounts to from $3.00 to $5.00/hr. depending on the way in which the material is written off. Radiographic inspection costs about the same when the radio-active material is rented. Ha (5b)

Crystal Structure of the β-phase of Aluminum-Bronze. Kchija Oninata. *Nature,* Vol. 126, Nov. 22, 1930, page 809.

A fine rod of 12.5% alloy measured at 650° C. showed that the β-phase has a body centered cubic super-lattice with the parameter equal to 5.887 A.U. A sample heated to 850° C. and quenched in H_2O showed a hexagonal lattice for the β'-phase with parameters a=11.13, c=6.342 and c/a=0.5698 with the parameter for the β-phase equal to 5.835 A. U. (5b)

X-Ray Analysis of the System Gold-Antimony and Silver-Tin (Röntgenanalyse der Systeme Gold-Antimon und Silber-Zinn). O. Nial, A. Almin & A. Westgren (University of Stockholm. *Zeitschrift für physikalische Chemie,* Sect. B, Vol. 14, Sept. 1931, pages 81-90.

In regard to the Au-Sb system, the former thermo-analytical establishments of Vogel (*Zeitschrift für anorganische Chemie,* Vol. 50, July 1906, pages 145-157) and the X-ray determinations of Ofteda! (*Zeitschrift für physikalische Chemie,* Vol. 135, Aug. 1928, pages 291-299) could be fully confirmed and yielded only one intermediate phase $AuSb_2$ which shows the same atomic arrangement as pyrite. The length of the unit cell amounts to 6.647 ± 0.005 A.U. The X-ray analysis of the Ag-Sn system is in accordance with A. J. Murphy's layout (*Journal Institute of Metals,* Vol. 35, 1926, page 107) and revealed a far reaching structural identity with the Ag-Sb alloys. The Ag-Sb system exhibits a phenomenon already met with in the Ag-Sb and Fe-N alloys: 2 phases ϵ and ϵ', the latter representing only a "little deformed type' of the first crystallographic structure. The authors found that the solubility of Sn in Ag amounts to 11.4 atomic per cent at 400° C. The parameter of the face-centered cubic lattice is increased by rising additions of Sn from 4.077 A.U. to 4.125 A.U. At 400° C., the homogeneity range of the ϵ-phase covers 13.3-19.7 atomic per cent Sn and 24-25.5 atomic per cent Sn for the ϵ' phase. EF (5b)

X-Ray Investigation of Certain Nickel-Steels of Low Thermal Expansion. G. Phragmen. *Iron & Coal Trades Review,* Vol. 123, July 10, 1931, pages 40-41.

The apparatus and test method are described. See *Metals & Alloys,* Vol. 2, Nov., 1931, page 254. Ha (5b)

On a Gallium-Zinc-Spinel (Über einen Gallium-Zinkspinell). F. Buschendorf (University of Göttingen). *Zeitschrift für physikalische Chemie,* Sect. B, Vol. 14, Oct. 1931, pages 297-303.

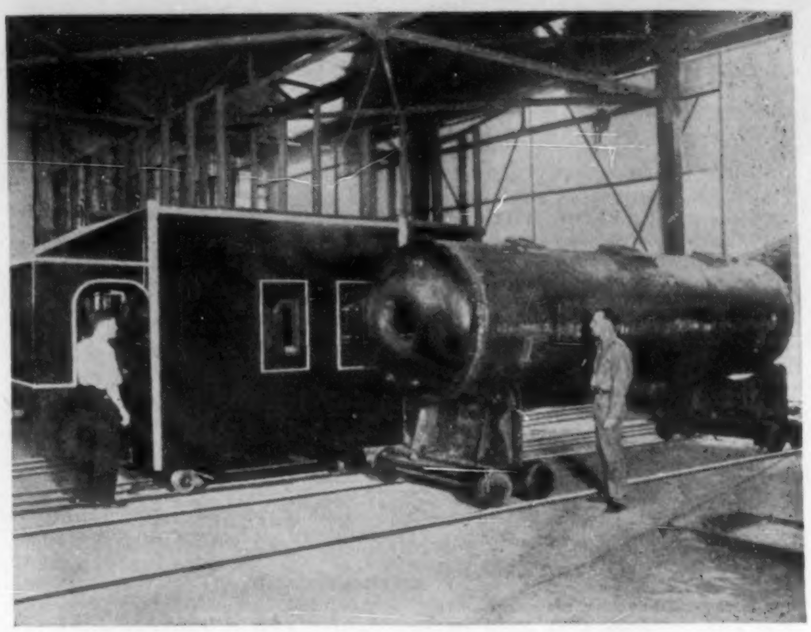
X-ray investigation pertaining to a zinc-gallate Ga_2ZnO_4 made up from ZnO and Ga_2O_3. The author proves that Al can be replaced by Ga in the zinc spinel without materially influencing the space lattice of the latter. EF (5b)

Investigation on the $\delta \rightarrow \gamma$ Transformation in the System Iron-Nickel (Untersuchungen über das Gebiet der $\delta \rightarrow \gamma$-Unwandlung in System Eisen-Nickel). H. Bennek & P. Schafmeister. *Archiv für Eisenhüttenwesen,* Vol. 5, Aug. 1931, pages 123-125.

After dealing with the results of previous investigations on the system Fe-Ni, the contradictory results of which are evidently due to the fact that the temperatures of equilibrium and the corresponding concentrations of the phases are effected by the cooling velocities, the authors re-established the diagram up to 50% Ni. The diagram is in satisfactory agreement with those established by D. Hansen & J. R. Freeman, *Journal Iron & Steel Institute,* Vol. 167, 1923, pages 301-321, and T. Kasé, *Science Reports Tohoku Imperial University,* Vol. 16, 1927, pages 491-513. GN (5b)

Separation and Changes of Properties in Supersaturated Silver-Copper Alloys (Entmischung und Eigenschaftsänderungen über sättiger Silber-Kupferlegierungen). N. Ageew, M. Hansen & G. Sachs. *Mitteilungprüfungsanstalten,* Sonderheft 18, 1931, pages 1-15; *Zeitschrift für Physik,* Vol. 66, Dec. 3, 1930, pages 350-376, 10 references.

The silver-rich and the copper-rich ends of the system were examined by X-ray methods with precision measurement of the lattice constants, by hardness measurements and by electrical conductivity measurements on quenched and annealed specimens. The equilibrium diagram is of the same type, showing maximum solid solubility at the eutectic temperature 779° C., diminishing with decreasing temperature. About 8½% Cu is soluble in Ag, and about 7% Cu in Ag at 779° C. At 200° C., however, only about 0.5% Cu is soluble in Ag, and less than 0.1% Ag in Cu. The work is largely concerned with a study of supersaturated alloys, one of 10.5% Ag in Cu quenched from 770° C. and annealed 24 hours at 300° C. has a lattice constant of 3.609 against 3.608 for pure Cu. The separation of the Ag is shown to be complete in 24 hours at 300° C. Precipitation of 50% of the Ag occurs in 9 hours at 300° and 190 hours at 250° C. Annealing the quenched alloy at 300° C. decreases the electrical resistance some 17% and raises the Brinell hardness from 65-70 to 90-95. Long annealing reduces the Brinell slightly below its maximum value in the 10.5% Ag alloy, but annealing even at 400° C. does not appreciably affect the Brinell of a 3.5% Ag alloy. Similarly, on the Ag-rich end, a 7.5% Cu quenched alloy annealed ½ hour at 250° or 10 hours at 200° C. rises from 60 to 150 Brinell, then falls to 110 or below on longer anneals, while an alloy of 2.3% Cu is practically unchanged at about 38 Brinell in hardness by long anneals at 200° and 250° C. and for the first 10 hours at 300°, but in 100 hours rises to 50 Brinell. Alloys of intermediate compositions show intermediate behavior. Quenching speed (cold water versus hot water or oil) has a large effect on the maximum hardness obtained on annealing. The alloys of 6.3% Cu with Ag and of 10.5 Ag with Cu both show a smaller decrease in resistance on annealing than is calculated by the rule of mixtures, by about 10%. Some abnormal effect is present which has not yet been clarified. From the similarity of the two ends of the system, it is probable that the same cause is working in both cases. When either Cu or Ag is precipitated from the supersaturated solid solutions, the appearance of some X-ray lines indicate that the precipitation does not occur uniformly throughout the mass, but that the solute is completely precipitated from portions of the alloy while other portions remained unchanged. The smearing of the diffraction lines of the newly formed lattice may be indicative of the formation of very small crystals or of strained crystals. Comparison of the intensity of the diffraction lines due to the new lattice with those due to the original lattice allow estimation of the fraction of the solute precipitated by any "aging" treatment. Upon "aging" a supersaturated Ag-rich single crystal was transformed into a multicrystal mass. HWG (5b)



Limits of Error for Piston Pins (Kolbenbolzen-Toleranzen). E. Koch. *Maschinenbau,* Vol. 10, July 2, 1931, pages 450-452.

The difficulties in accurately determining the limits of error in bored pistons and piston pins are discussed. It is shown that these parts cannot be interchanged, and that it is not yet possible to produce those which may be interchanged. MAB (6)

Plasticity Tests with Steel Pipes (Fliessversuche an Stahlrohren). *Zeitschrift Verein deutscher Ingenieure,* Vol. 75, Mar. 28, 1931, page 387.

Tests with combined stress of maximum 15 ton tensile strength and 150 mkg. torques on 400 mm. long pipes confirmed the usefulness of the formulas of Hencky. Ha (6)

Accelerated Cracking of Mild Steel (Boiler Plate) Under Repeated Bending. Rosenhain & Murphy. *Engineer,* Vol. 151, May 22, 1931, page 566.

Abstract of paper read before the Iron & Steel Institute May, 1931. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 247. LFM (6)

Magnetic Method of Testing Welds. *Machinery,* Vol. 37, Apr. 1931, pages 624-625.

Only rather superficial defects can be detected by magnetic tests with iron filings strewn over the weld. The application of this method is illustrated. Ha (6)

One Million Pound Testing Machine for Testing Wire Rope Specimens. Trevor N. Treen & T. Avery. *Scale Journal,* Vol. 18, Oct. 1931, pages 3-4.

A detailed description of a machine for testing wire rope samples of 11 in. maximum circumference and 6 ft. unstretched length to a capacity of 1,000,000 lbs. The machine is equipped with automatic recording apparatus and electrically propelled and controlled poise. Ha (6)

Testing Methods for Cast Iron (Beproevingsmethoden voor Gietijzer). E. B. Wolff. *De Gieterij,* Vol. 4, Oct. 1930, pages 164-168.

The author discusses the various mechanical testing methods applied to cast iron and concludes: (1) the practice of large test pieces should be continued but with a better standardization of casting practice; (2) test pieces should not form part of the casting; (3) bending tests are more important than tensile tests; (4) division into 4 classes with tensile strengths of 14, 18, 22 and 26 kg./mm.^{2} is desirable; (5) the diameter of the test pieces should agree somewhat with that of the casting by dividing castings into 3 groups, viz., those thinner than 20 mm., those having dimensions between 20 and 50 mm. and those exceeding 50 mm. in diameter. HSvK (6)

The Deformation Process in Test Bars (Beiträge zum Verformungsvorgang im Zerreisstäben). *Stahl und Eisen,* Vol. 51, Sept. 3, 1931, pages 1116-1117.

Discussion between N. Dawidenko, G. Sajzew & W. Tafel on the paper by W. Tafel & H. Scholz in *Archiv für Eisenhüttenwesen,* Vol. 3, Feb. 1931, pages 545-552. See *Metals & Alloys,* Vol. 5, July 1930, page 629. GN (6)

Detecting Deformation of Shafts. O. P. van Steewen. *American Machinist.* Vol. 75, Oct. 1, 1931, pages 530-532.

The testing machine consists of 5 parts: (1) a large lathe resting on a firm base, (2) a framework which runs along the ways of the lathe and a caliper gage for measuring the diameter of the object, (3) an instrument for marking the outside wall of the object, (4) a horizontal comparator for measuring the distances and variations between the markings before and after every treatment of the object under observation, (5) an arrangement whereby the temperature can be kept within certain limits. The machine is in use in the shops of the A. E. G., Berlin. Ha (6)

Hardness Testing Superhard Materials. A. F. Shore. *American Machinist,* Vol. 75, Aug. 6, 1931, page 238.

Nitrided steels, tungsten and tantalum carbides can no longer be tested for hardness by the usual routine methods because of their immense hardness. Tests must be applied that disregard surface conditions and take a reading slightly below the surface. A chart is given showing, for different metals, the penetration depths and the force required for it. The penetrator is a hemispherical diamond. The method is described briefly. Ha (6)

A Magnetic Testing Method for Boiler Tubes (Ueber ein magnetisches Verfahren zur Prüfung von Kesselrohren). F. Wever & A. Otto. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung,* Vol. 12, No. 24, Report No. 169, 1930, pages 373-387; *Stahl und Eisen,* Vol. 51, Apr. 1931, pages 466-468.

The authors developed a magnetic testing method for tubes. After preliminary tests with various types of d.c. and a.c. magnetizing, a dispersion current method with d.c. magnetizing was used. The magnetizing coil together with the testing coil is running over the tested tube with constant speed. In magnetizing the tube with constant magnetizing force, electromotoric forces are brought about in the testing spool by the dispersion fields which originate at the locations of magnetic disturbances. The testing spool is connected with a galvanometer. In testing low carbon steel tubes, 2 distinct types of magnetic disturbances were observed whether a high or a low magnetizing field strength is used. Cold work as it locally occurs while the tubes are straightened after annealing and non-uniformity of the structure are detected with the low field strength. Periodical changes of the diameter of the tubes, as caused by cold drawing, are detected with a high field strength. In further tests it is shown that cracks, inclusions and other failures can be detected which would not have been observed otherwise. GN (6)

A New Type of Testing Machine. *Foundry Trade Journal,* Vol. 45, July 30, 1931, page 75.

A description of the recently developed Tensometer, a small portable combination tensile-and Brinell-testing machine, weighing only 20 lb. The article is accompanied by 2 figs., one showing the plan and elevations of the machine, and the other a photograph. The test pieces used in the machine measure 0.6275 in. between the shoulders and have a diameter of 0.1593 in. OWE (6)

Fatigue of Metals and Alloys (6f)

The abstracts appearing under this heading are prepared in coöperation with A.S.T.M. Research Committee on Fatigue of Metals.

Accelerated Cracking of Mild Steel (Boiler Plate) under Repeated Bending. W. Rosenhain & A. J. Murphy. *Iron & Coal Trades Review,* Vol. 122, May 8, 1931, pages 739-743; June 12, 1931, page 951.

With discussion. In the course of investigations on a considerable number of failures in boiler plates and tubes, evidence has been found that the damage has been done at points where local flexure may occur as a result of changes of pressure and temperature. In order to imitate these stresses, test pieces from boiler plates were subjected to bending backward and forward through an angle of 15° each way and the number of bends after which the first visible crack appeared determined. The pieces were bent in air and immersed in water, brine and caustic soda solution. The surrounding medium did not have any great influence for short durations, but after 24 hrs., the endurance is markedly reduced in the tests with brine and water; water is more severe than brine. Micrographs are reproduced. Ha (6f)

An Investigation of Steels for Aircraft Engine Valve Springs. A. Swan, H. Sutton & W. D. Douglas. *Proceeding Institution Mechanical Engineers,* Vol. 120, Feb. 1931, pages 261-299.

The cause of failures in valve springs which have to perform the most arduous duty in service were investigated by making static tensile tests, static torsion tests and fluctuating torsion tests on a high quality steel wire from which springs were made. The apparatus and methods of these tests are described in detail. From the detailed reproduction of test data, the following results are stated. Most of the wires examined show pronounced decarburization at the surface. Removal of the surface layer has the effect of increasing the apparent safe range of stress and of reducing the variability. Oil-quenching from temperatures relatively low, but sufficiently high to secure effective hardening, followed by tempering at a normal temperature gave the best endurance properties. A possible explanation of the relatively low ratio of fatigue range to tensile strength of the harder wires lies in the residual stress following the hardening and tempering operations. Tests have revealed that considerable compressive residual stresses were present in the outer layers of heat-treated test pieces. For further details, the paper must be referred to. Ha (6f)

Crackless Plasticity, a New Property of Metals. H. F. Moore (University of Illinois). *Iron Age,* Vol. 128, Sept. 10, 1931, pages 674-677, 721.

An important property of steel is its ability to stand occasional overstress without the development of a crack which, in subsequent service, spreads to failure. Crackless plasticity of steel is not dependent on ductility as measured in tension or cold-bend-test. Suggested methods of experimental study includes fatigue tests following a period of overstress, notched bar impact tests and tests of damping of vibrations in the metal. Heat treated spring steel, as well as heat treated alloy steel, does not show a high degree of crackless plasticity under repeated stress. Another indication of the importance of crackless plasticity of metals is found in the behavior of notched specimens under repeated stress. VSP (6f)

The Increase of Fatigue Strength of Notched Constructions (Zur Steigerung der Dauerfestigkeit gekerbter Konstruktionen). A. Thum. *Zeitschrift Verein deutscher Ingenieure,* Vol. 75, Oct. 24, 1931, pages 1328-1330.

Frequently notch effects cannot be avoided in structures because of the requirements of shape, arrangement of oil holes, etc. The author describes a method of producing stresses in the piece as an effective means of counteracting the notch effect. These inner stresses must be arranged in such a manner that they create, by a plastic deformation in the surface, a compressive tension which acts like a clamp around the notch and tries to protect it against formation of cracks which usually lead to fracture later. Ha (6f)

High Frequency Endurance Tests of Light Alloy Sheet Materials. *National Advisory Committee for Aeronautics,* 17th annual report 1931, pages 34-35.

Endurance limits at 12,000 cycles/min. were determined on high-frequency air-driven flexural endurance machines at the Bureau of Standards. (See *Metals & Alloys,* Vol. 1, Oct. 1929, page 145; Jan. 1930, page 332). Results were:

Alloy	Composition Cu	Mn	Mg	Si	Treatment	Direction of Specimen	Endurance Limit lbs./in.^{2}
17 ST	4	0.5	0.5	—	Quenched & Aged	L & T	15,000
25 ST	4.5	0.8	—	0.8	Quenched & Aged	(L	14,000
						(T	15,000
25 SW	4.5	0.8	—	0.8	Quenched Not Aged	(L	11,000
						(T	13,000
51 ST	—	—	0.6	1.0	Quenched & Aged	L & T	13,000
51 SW	—	—	0.6	1.0	Quenched Not Aged	(L	10,500
						(T	13,000
2 SH (Com'l Al)	—	—	—	—	Hard Rolled	L & T	10,000
3 SH	—	1.25	—	—	Hard Rolled	L & T	12,000
M H (Com'l Mg)					Hard Rolled	L & T	6,000
M AH	4% Al, 0. 4% Mn, bal. Mg					L & T	5,000 to 6,000

The method was not applicable to these materials in the annealed state, to heat-treated Alclad or to steel. Endurance testing to 100 million cycles in motor-driven flexural machines at 900 cycles/min. gave 16,000 lbs./in.^{2} for longitudinal and 14,000 for transverse specimens on quenched and aged 17 ST. Alclad 17 ST, i.e., the same alloy with Al layers on the surfaces of the sheet, similarly quenched and aged, showed 10,500 lbs./in.^{2} in both directions. A "special" 17 ST (composition not given) quenched and aged showed 19,000 lbs./in.^{2} longitudinal and 21,000 transverse. The same as Alclad, i.e., with Al layers, gave 13,000 longitudinal, 11,200 transverse. HWG (6f)

Surfaces. *Metallurgist*, Jan. 1931, pages 3-4.

Recent work on the effect of alternating stress on metals has called attention to the effect of the condition of the surface. Heat treated spring plates, for example, in the condition as ordinarily manufactured develop only a fraction of the true fatigue strength of the material but this can be closely approached by the same plates if they are first ground and polished in order to remove the rough surface layer. Surface decarburization, pitting or roughening from oxidation, and minute surface cracks resulting from quenching operations have been suggested as causes. Surface corrosion also causes loss of endurance strength. The requirement of resistance to corrosion is best met by materials which protect themselves by the spontaneous formation of a resistant surface film. The plating or covering of one metal with another such as chromium plating and the coating of aluminum alloy with pure aluminum are examples. Such coatings, however, must be deposited free of stress since, if the piece is subjected to alternating stress, the initial stress of the coating becomes superposed on the working stress and cracking of the surface layer may result. If this occurs, the crack will generally be propagated through the underlying steel, causing failure below the endurance range of the uncoated steel. The difficulties connected with the use of surface coatings would suggest that the soundest direction for future progress is likely to lie in the development of spontaneously corrosion-resisting materials of the type of the rust-resisting steels. VVK (6f)

Influence of Corrosion on Fatigue of Notched Specimens. T. S. Fuller. *Mining & Metallurgy*, Vol. 12, Oct. 1931, page 446.

Results of tests with a Ni steel of 3.5% Ni and 0.35% C, which was notched in a definite manner: The basis for consideration is the endurance limit of 58,000 lbs./in.^{2} of the unnotched specimen. In air at room temperature in the absence of corrosion, the value was reduced by notching to 32,000 lbs. by exposure to an atmosphere of wet steam and air to 31,000 lbs., then tested with a jet of steam playing directly on the notched section, to 27,000 lbs. The tests are described in detail. Ha (6f)

"Damping" of Materials under Alternating Stresses. *Metallurgist*, Jan. 1931, pages 13-15.

An extended abstract of a paper on this subject by Dr. O. Föppl in *Zeitschrift Verein deutscher Ingenieure*, Oct. 4th, 1930. The view held some years ago that the onset of plastic distortion was the feature that controlled the fatigue strength of a material has now been definitely discarded. On this view, the limiting fatigue strength coincides with the elastic limit, but it is now well known that the fatigue range may be high enough to allow a small amount of plastic distortion to occur during each stress cycle. It is stated that in some steels the fatigue strength is more than 4 times the highest stress at which the distortion can be said to be purely elastic. When a material is subjected to alternating stress under which the distortion is partly elastic and partly plastic, it is well known that some of the energy supplied is converted into heat in the interior of the material during each cycle, and another property of the material now comes into action, which, for want of a better term has been given the name "Dämpfung" in German, which may be rendered as "damping." The stress strain curve for a cycle takes the form of the familiar hysteresis loop, and the "damping" of the material, which is defined as the energy dissipated/cycle/unit volume, is given by the area of the loop. A non-dimensional damping number, known as the relative damping, φ, which is the ratio of the damping to the total energy of deformation stored in the specimen when strained to the limit of the stress cycle, is used. A steel of large damping capacity will not fail under vibratory stresses as quickly as one of small damping capacity. Methods of measuring damping are given. The relation between damping under direct stresses and under shear is also discussed. VVK (6f)

What We Know of Fatigue. *Engineering News Record*, Vol. 106, Apr. 16, 1931, pages 651-653.

A summary of present knowledge of endurance of metal under repeated stress and its correlation to treatment by heat and working. Ha (6f)

The Effect of Surface on the Fatigue Resistance of Spring Steels. Conditions Produced by Heat Treatment. *Iron & Coal Trades Review*, Vol. 123, Oct. 2, 1931, pages 489-490.

The following conclusions concerning the properties of spring steels have been derived from extensive experiments. Minute surface markings, probably cracks on the surface of quenched-and-tempered steels, do not seem to have any appreciable effect on the fatigue-resistance. Decarburization and other heat treatments show a reduction of the endurance fatigue limit of sometimes less than half if the value of the completely polished surface is taken as unity. The summary of results of rotating cantilever fatigue tests and plane-bending fatigue tests must be seen in the tables accompanying the paper. The tests show that the microscopic examination of a surface after normalizing is likely to be misleading where the original decarburized layer is possibly less than 0.001 in. deep. The mechanical explanation (that fatigue cracks commence in a soft surface layer which has an intrinsically low fatigue resistance and are then propagated by stress concentration into the more highly resistant material below) gives a general explanation of the fatigue failures at low stresses. In general, the tests suggest that the greater the decarburization of the surface layer, the lower is the fatigue resistance. It is probable that the intrinsic fatigue resistance of the surface layer is approximately proportional to its hardness and diminishes with a decrease in the C content. Where a high fatigue resistance is required in a hardened-and-tempered steel, the surface decarburization of the surface in the heat treatment should be eliminated or reduced to a minimum. Ha (6f)

ELECTRO-CHEMISTRY (7)

Electroplating (7a)

Electroplating on Aluminum. Harold K. Work (Aluminum Company of America). *Metal Cleaning & Finishing*, Vol. 2, Sept. 1930, pages 777-780.

In plating commercially pure Al, the metal is cleaned, dipped for 10-15 secs. in 1 part 48-52% HF and 9 parts H_2O and rinsed in cold H_2O. It is then dipped in a solution of 37 oz. $NiCl_2$, 0.2 gal. HCl (sp. gr. 1.18), and 1 gal. H_2O at 75°-80° F. The time of immersion must be carefully determined by plating specimens with different periods in the dip, and then bending or breaking them. A good plate will not flake off in this test. A dip of 35 secs. usually gives good results. After rinsing the parts, they are plated at 15 amp./ft.^{2} in a bath of 19 oz. $NiSO_4$, 10 oz. $NaSO_4$, 2 oz. NH_4Cl, and 2 oz. H_3BO_3/gal. solution. Time of plating should be determined to give the desired corrosion resistance. Other Ni solutions such as are used on Zn may be substituted. After plating, the parts are rinsed in cold H_2O, dipped in hot H_2O, buffed, cleaned, and plated with any desired metal. In plating strong alloys and sheet containing Mn, the articles after being cleaned and dipped in HF are immersed at 75°-80° F. in ½ gal. HCl (sp. gr. 1.18), ½ gal. H_2O, and ½ oz. $MnSO_4.2H_2O$. The time of immersion must be carefully determined by experiment. The rest of the plating procedure is unchanged. The heat treated metal gives a plated product that is more resistant to corrosion than the untreated metal. Castings require still a different etching process. The etching solution consists of 3 parts HNO_3 (sp. gr. 1.42) and 1 part HF (48-52%) at 75°-80° F. Proper time must be carefully determined by test as in the other cases. Usually the proper time of dip is 15-30 secs. for die castings, and 60-120 secs. for sand castings. Containers for the dip should be Pb lined and painted with a mixtures of 1 part beeswax to 4 parts paraffin. MS (7a)

Chromium Deposits Directly on Aluminum. Harold K. Work & Charles J. Slunder (Aluminum Company of America). The *Metal Industry*, N. Y., Vol. 29, June 1931, pages 243-245.

Paper presented at the Electrochemical Society, Birmingham, Ala., April 1931. Using ordinary chromium plating baths, light and heavy chromium deposits on aluminum were obtained. Corrosion resistance was good both to outdoor exposure and to mild alkalies. 7 references. See *Metals & Alloys*, Vol. 2, Sept. 1931, page 174. PRK (7a)

Comparative Measurement of Throwing Power in Electroplating Practice. L. K. Wright. *Metal Industry*, N. Y., Vol. 28, Nov. 1930, pages 522-523; *Oberflächentechnik*, Vol. 8, July 7, 1931, pages 142-143.

Several methods have from time to time been advocated but usually results represent nothing of great value in commercial applications. Method advocated by the author is one which utilizes an instrument in which tubes are quickly inserted and tested. The instrument consists of a rubber plate, wherein is the current distribution plate, the center of which is pierced and threaded to receive a test tube, the same being inserted from the rear. The instrument requires very little calculation, is simple and capable of presenting accurate data. Ha+VSP (7a)

Electroplating on Aluminum from Cyanide Solutions. H. K. Work. *Preprint, American Electrochemical Society*, Vol. 60, Sept. 1931, pages 53-57; *Metal Industry*, N. Y., Vol. 29, Oct. 1931, pages 436-437.

Of the various cyanide plating baths, the cyanide zinc bath containing no strong alkali proved most practical. Details follow:

Bath composition:	g./l.	oz./gal
$Zn(CN)_2$	30	4
NaCN	30	4
Ammonia water, 28%	30	4
Peptone, or	1	0.12
Gelatin	5	0.67

Temperature: 20°-23° C.
Current density: 0.5 amp./dm.^{2}, 5 amp./ft.^{2}.
Preliminary treatment: Cleaning in mild alkali, followed by pickling in 5% HF. PRK+LCP (7a)

Chromium Plating for Wear Resistance. Robert D. Zimmerman (Ingersoll Rand Co.) *Iron Age*, Vol. 127, June 18, 1931, pages 1982-1984.

Supplement to an article appearing *Iron Age*, Vol. 127, June 4, 1931. Anodes vary in size from 1/16 in. to 24 ins. Production fixtures consist of: (1) those for plating a number of similar parts at the same time; (2) those for plating a number of identical parts. Usual amount of plate removed in grinding is about 0.003 in. on the diameter of a round piece. Discusses plate finishing. VSP (7a)

Pure Zinc Galvanizing Process. L. D. Whitehead. *Wire & Wire Products*, Vol. 6, June 1931, pages 223-225.

In hot-galvanizing iron, the zinc is always, and unavoidably, contaminated with iron, to the extent of at least 2½%. The value of pure zinc as a protective agent is in this manner considerably reduced. In the new electric galvanizing method which is described, the wire, after being drawn, is taken straight to the galvanizing shop without any other preparation. Then the wire is first drawn through a lead annealing furnace which keeps the temperature within very narrow limits; passed through a very dilute acid bath as a cleanser; and wound over drums, one of which is immersed in the galvanizing bath. Only a very small galvanizing tank is necessary, as compared with the long ones required for the hot process. As the zinc is deposited in its purest form, a thinner coating suffices; moreover, it is not brittle and has a greater ductility. If 1/3 of the weight which must necessarily be deposited by the hot galvanizing method is deposited electrically, it is shown to give the same resistance to corrosion. A coating of equal thickness, deposited electrically, has a resisting power 10 times as great as that deposited by the hot-galvanizing process. Another consideration in favor of the electrolytic process is that there are no noxious fumes present as in hot-galvanizing. Ha (7a)

Working Methods in Chromium Plating (Die Arbeitsmethoden der Galvanischen Verchromung). *Oberflächentechnik,* Vol. 8, Apr. 7, 1931, pages 77-79.

Valuable information covering the working methods used in chromium plating. Description of the detailed chemical processes occurring in the course of plating and the conditions favoring the formation of bright, dull, burnt, highly corrosion-resistant and tenaciously adhering coatings. Thus, for corrosion-resistant and tightly adhering chromium coating and nickel as intermediate layer, the strict adherence to the following rule must be observed: Nickel bath: pH value, 5.2-5.8; temperature of bath, 40-50° C.; metal salt concentration, as high as possible; thickness of coating, 0.025 mm. Chromium bath: 15-20 min. at 3.4-3.5 volts; current density, 5-15 amp./dm.^{2} for cathodic surface; temperature of bath, 30-45° C.; bath concentration, 32-35° Bé; lead as anode and ratio of anodic surface to cathodic 1.5:1. Bad nickel-chromium double coatings can be removed conveniently electrolytically—material involved as anode, lead as cathode, 5-8 volts, anodic current density 1.5 amp./dm.^{2}, sulphuric acid of 56° Bé, as electrolyte, to which is added either arsenic acid or lead acetate. ER (7a)

Electrometallurgy (7b)

Electrolytic Refining of Aluminum and Aluminum Alloys in a $AlCl_3$-NaCl Melt. (Elektrolytisches Raffinieren des Aluminiums und Aluminieren in einer $AlCl_3$-NaCl-Schmelze.) W. A. Plotnikow, N. S. Fortunatow & W. P. Maschowetz. *Zeitschrift für Elektrochemie,* Vol. 37, Feb. 1931, pages 83-88.

The electrolytic refining of aluminum is a useful process for obtaining very pure aluminum and for separating the metal from its alloys in scrap, borings and the like. The principal value of electrolytic refining, however, lies in the possibility of obtaining the metal from relatively low-grade ores and purifying it, at a lower operating cost than that incurred in prevailing metallurgical methods. The difficulty is in finding an electrolytic process which fully meets the requirements both of efficacy and economy. An essential factor in success is to find a suitable non-aqueous electrolyte, in which the electrolysis can be effected at a moderate temperature. In an investigation made at the Ukrainian Academy of Sciences, at Kiev, various double salts containing aluminum were studied with this in mind. The best results were obtained with aluminum and sodium chlorides, which were used as long ago as 1854 for electrolytic preparation of aluminum metal. By suitable proportioning of the chlorides and proper choice of conditions, it was found possible to refine aluminum even when its iron content is very high. Iron and copper are the only cathode metals on which satisfactory deposits were obtained. (7b)

The Refining of Silver. C. Campbell. *Electrical Review,* Vol. 109, Aug. 21, 1931, page 275.

The electrolytic method is now the most satisfactory; the Balbach-Thum process is the most generally applied in England. To secure uninterrupted operation and prevent losses by defective deposits, 2 sets of tanks are always run in parallel. The current density is maintained at 50 amp./ft.^{2}. The cells consist of shallow glazed porcelain troughs with horizontal bottoms lined with Acheson graphite. The graphite forms the cathode; the deposit is permitted to form on top of the cathode for the period of one shift (8 hrs.), after which it is removed. The area of the cathode is about 8 ft. square. The anodes are plates of crude Ag otbained from various melting operations. The electrolyte consists of a 0.5% solution of nitric acid; the Ag content is maintained at 3%. The Ag obtained has a purity of 99.9% of Ag. The remainder is made up of 0.02% moisture, 0.03% C, 0.001-0.005% Au. The treatment of the anode slimes containing 90-94% Au, 4% Pt and 0.4% palladium, and the separation of these metals is briefly described. The importance of maintaining a constant flow of fresh air to remove the noxious nitric oxide fumes is noted. Ha (7b)

Production of Magnesium by the Electrolysis of Fused Fluorides containing Magnesium Oxide (Die elektrolytische Gewinnung des Magnesiums aus Magnesiumsoxydhaltigen Fluoridschmelzen). G. Grube & H. Henne. *Zeitschrift für Elektrochemie,* Vol. 36, Mar. 1930, pages 129-138; *Chimie et Industrie,* Vol. 24, Sept. 1930, page 607.

In this investigation, the authors used calcium fluoride instead of barium fluoride. As a part of their work they determined the equilibrium diagram for a mixture of fluorides. It was found that the most interesting of 2 ternary eutectics was a combination of $MgF_2 \cdot CaF_2$ and $MgF \cdot NaF$ (melting point 894° C.). The electrolysis was carried out in a copper crucible with an iron cathode and a graphite anode. The cathode was surrounded by a copper bell in which there was a H atmosphere. Several mixtures were used at temperatures 40° C. above their melting point. It was found that the mixture of the eutectic composition gave only Mg. If barium fluoride was added to the bath as a fourth constituent, the current efficiency, which is a function of the cathode current density, increased. As a result the temperature of the electrolysis was lowered but Na appeared at the cathode. These results confirm on the whole those of previous investigations. (7b)

Electro-Metallurgical Deposition. *Electrical Review,* Vol. 108, June 12, 1931, pages 983-984.

The fundamentals of metal deposition from electrolytes are explained briefly. The importance of ascertaining the polarization of electrodes for the determination of the voltages to be applied in the process are discussed and the connections between tanks and dynamos and dimensions of electrodes are described. Ha (7b)

An Electrolytic Method of Preparing Alkaline Metals in Discharge-Tubes (Eine elektrolytische Darstellungsmethode von Alkalimetallen in Entladungsröhren). M. Forro & E. Tatai (University of Budapest). *Zeitschrift für technische Physik,* Vol. 12, Apr. 1931, pages 256-262.

An electrolytic method was developed for the deposition of alkaline metals in vacuo. The experiments refer to K, Rb and Cs. EF (7b)

METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

The Surface Treatment of Aluminum (Die Oberflächenbehandlung von Aluminium). *Oberflächentechnik,* Vol. 8, Sept. 1, 1931, pages 187-189; *British Industrial Finishing,* Vol. 2, May 1931, pages 76-80; June 1931, pages 102-104.

Surface treatments comprise 2 groups, one mechanical and one chemical and electro-chemical. In all cases, an entirely clean surface is required. Solutions for degreasing and deoxidizing are mentioned. One mechanical treatment consists of heating the Al to 300-500° C., depositing a layer of Sn and then pressing on under hydraulic pressure a thin, cleaned sheet of heavy metal. Lautal, Duralplat and Alclad are similar products. Covering with paints, lacquers or enamels also belongs in this class. It is briefly treated and recipes are given. Of the chemical, the electro-chemical coating methods are most important. Electrolytic bath recipes are given and methods for plating with Ni, Cu and Zn are explained. The 2 latter metals can be deposited also in a physico-chemical process by boiling the Al in suitable solutions. Colored coatings can be obtained by the Fescol and Alumilite processes. A solution is given for obtaining a fine black color on Ni plated Al with steel anodes. Ha (8)

Metal Spraying as Protection Against Corrosion (Das Metallspritzverfahren als Schutz gegen Korrosion). H. Pauschardt. *Korrosion & Metallschutz,* Vol. 7, June 1931, pages 139-145.

Includes discussion. After briefly summarizing the theory and process of metallic spraying in the introduction, the author reports his own experiments carried out with sprayed metallic plates exposed to atmospheric and liquid attack of various degrees of severity. The primary interest was the prevention of corrosion in sea-water and of the growth of marine animals and vegetation. The materials employed for the spray and coating, respectively, were as follows: (1) cadmium; (2) zinc + bakelite coating; (3) zinc + mercury layer (particularly against maritime animals); (4) zinc + tin + bakelite; (5) aluminum-bronze (Al-Cu); (6) aluminum + zinc + bakelite; (7) aluminum + zinc. An additional set of experiments refer to Al-plates coated by a metallic spray of Cd. The original paper, presented before the Reichsausschuss für Metallschutz, Kiel, 1930, must be consulted for the wealth of results which are set forth in a large table. EF (8)

An Electric Galvanizing Furnace Permits Close Temperature Control. S. Z. Owen (Westinghouse Elec. & Mfg. Co.). *Electric Journal,* Vol. 28, Nov. 1931, pages 631-632.

An electrically-heated galvanizing furnace has been installed for work on small castings, conduits and pipes, and similar material in street-lighting equipment. Its rating is 75 kw. 200-v., 3-phase. The vessel weighs over 2 tons and holds 8 tons of spelter. The 6 heating elements—2 on each side and one at each end—are made of Ni-Cr resistance wire supported in porcelains and are easily removable without disturbing the vessel. The enclosing shell serves as a mounting for insulators, jumpers, terminal boards and covers, and as a support for an insulated hinged cover. The cover, in 2 halves for convenience in operation, is made by an inner alloy sheet and a top steel sheet, filled between with 3 inches of mineral wool insulating material. Thermocouple control of the chamber temperature and bath temperature insure close temperature control. WHB (8)

Homogeneous Lead Deposition with the Aid of the Oxy-Acetylene Blow Pipe. *Welding News,* Vol. 2, July 1931, pages 20-21.

At the present time, industry makes use of a Pb covering of metals which is carried out in 2 ways: (1) on all metals, by means of sheets of Pb suitably shaped and fixed in position by oxy-acetylene welding; (2) chiefly on steel, by depositing molten Pb by means of the blow pipe on all the surfaces to be protected. The procedures are described in general. Steel is often tinned first to assure an absolutely dense and homogeneous Pb covering. Ha (8)

New Methods and Equipment Aid Coating Industry. *Steel,* Vol. 88, Jan. 1, 1931, pages 288, 361.

The past year has seen many improvements in the enameling, pickling, galvanizing and polishing of metals. These include 2 new continuous furnaces for porcelain enameling, an acid-proof reinforced concrete tank for pickling, the use of small percentages of Al in zinc for galvanizing, better methods of galvanizing sheet and wire, of handling dross, and of regulating the speed of galvanizing machinery, and the development of machines for polishing sheet, tin plate, and stainless steels. JN (8)

Advantages of Oxide Films as Bases for Aluminum Pigmented Surface Coatings for Aluminum Alloys. R. W. Buzzard & W. H. Mutchler (Bureau of Standards). *Technical Note* No. 400, *National Advisory Committee for Aeronautics,* Nov. 1931, mimeographed. 16 pages, 13 figures, 10 references.

Anodic coatings on aluminum alloys, produced by electrolysis in sodium-hydrogen phosphate, ammonium hydroxide, ammonium sulphide, oxalic acid, sulphuric acid, or chromic acid, especially chromic acid, have some corrosion resistance, but it is not very great. Pure Al coatings, as in Alclad, offer the best resistance, but there is still a need for other protective methods. Varnish type coatings applied over untreated duralumin have only about the same degree of protection as a grease coating over an anodic film. Use of the anodic coating as a priming coat over which aluminum-pigmented varnish is applied, gives good results. Tests by the salt spray method, intermittent immersion in NaCl-H_2O_2 solution, on unstressed, on statically stressed specimens, and on specimens subjected to repeated flexural stresses as well as atmospheric exposure tests are recorded. They show that under all conditions of test the combination of anodic treated plus the aluminum pigmented spar varnish was far superior to either alone. The combination stood up for nearly 3 years in exposure tests at Hampton Roads; intercrystalline attack of the duralumin had just started in 3 years. Alclad duralumin similarly exposed showed no intercrystalline corrosion at all in 3½ years. HWG (8)

INDUSTRIAL USES & APPLICATIONS (9)

Nickel Alloys in Automotive Manufacture. THOMAS H. WICKENDEN. *S. A. E. Journal*, Oct. 1931, pages 328-331.

Many uses of Ni in the automotive industry are listed. It is used in cast iron to promote uniform hardness and good wearing qualities, in castings of varying section, without excessively hard spots. Cylinders, cylinder-heads, pistons, exhaust manifolds and brake-drums are among the chief engine and automobile parts in which nickel cast iron is used. It is also coming into extensive use in heavy dies for pressing fenders and large parts for automobile bodies. The discussion deals chiefly with the use and heat-treatment of nickel iron. The effect of annealing and heat-treatment on permanency of form and strength is touched upon, and vagaries of the expansion ratio of high-nickel-alloy steels are recounted. WAT (9)

The Surface Treatment of the Zinc for Use as Printing Plate (Die Oberflächenbearbeitung des Zinks zur Verwendung als Druckplatte). EUGEN WERNER. *Oberflächentechnik*, Vol. 8, Oct. 20, 1931, pages 215-217.

A detailed description of the development, the process and the preparation of zinc plates for zincotypography; that is, printing from prepared zinc plates instead of from stone or wood. Ha (9)

Refrigeration Units Require Quality Metals. H. M. WILLIAMS (Frigidaire Corp.). *Metal Progress*, Vol. 20, Aug. 1931, pages 39-45.

The author discusses the refrigerating cycle and necessity for corrosion resistance in materials of construction. Corrosion tests of various kinds are discussed. Development of ice tray materials, improved copper and brass parts in the evaporator, tubing and joining materials, control equipment and cabinet finishes are discussed. WLC (9)

Welded Cranes. H. SCHMITT. *Engineering Progress*, Vol. 12, Oct. 1931, pages 222-223.

General remarks on the advantages, with illustrations of examples. See also *Metals & Alloys*, Vol. 2, Oct. 1931, page 218. Ha (9)

The Effect of Short Circuit Currents on the Strength of Transmission Wires of Aluminum and Copper (Die Einwirkung von Kurzschlussströmen auf die Festigkeit von Leitungsseilen aus Aluminium und Kupfer). F. WOEHR. *Aluminium, Hauszeitschrift V.A.W. Erftwerk*, Vol. 3, July-Aug. 1931, pages 271-276.

Tests to decide to what extent Al wires (in comparison with Cu wires) are reduced in strength by very large currents of short duration as they occur during short circuits are described. The beginning of a reduction in strength was found, for Al, at about 140°-150° C., for Cu at 170°-180° C. The duration of the short circuit up to one sec. had no influence. In stranded cables, all layers were influenced in the same way. From the economical point of view, the use of Al is often preferable. Ha (9)

Corona on Copper and Aluminum Wires (Korona an Kupfer- und Aluminiumseilen). F. WOEHR. *Aluminium, Hauszeitschrift V.A.W. Erftwerk*, Vol. 3, July-Aug. 1931, page 266.

General remarks on the nature and dependence on weather conditions of corona losses of transmission lines. Since the diameters of Al wires are usually larger, the corona losses are smaller. The following table gives the voltage in kw. for lines of different sections at which the corona just begins to appear:

Section mm.²	Material Aluminum Old	New	Copper Old	New
70	47	45	40	31
95	56	43	48	40
120	60	49	42	40

The condition of the surface is of importance as can be seen from the difference between the old and the new material. Ha (9)

Influence of Corona Phenomena on Transmission Wires (Einfluss von Korona-Erscheinungen auf Freileitungsdrähte). v. ZEERLEDER. *Aluminium, Hauszeitschrift V.A.W. Erftwerk*, Vol. 3, July-Aug. 1931, pages 267-269.

On the basis of theoretical considerations, experience and experiments, it is shown that overhead lines of Al and Al alloys (for instance, aldrey) behave just as well under the corona effect as Cu. The tests were of a chemical and physical nature; they are described in full. Ha (9)

Welded Steel Cases for Loading Coils. C. R. YOUNG. *Bell Laboratories Record*, Vol. 9, July 1931, pages 517-522.

Loading coils, that is induction coils, used to counteract the capacitance of electric cables must be carefully protected from atmospheric and other damaging influences. A method of placing them in welded steel cases is described. Ha (9)

Repair Delays Reduced by Oxy-Acetylene Welding. F. A. WESTBROOK. *Welding*, Vol. 2, Nov. 1931, pages 742-743.

The successful application of bronze and other welding rods has contributed greatly to the profitable operation of a western mine. Ha (9)

Steel Wire for Heading. JAMES VINCENT. *American Machinist*, Vol. 75, Sept. 3, 1931, pages 388-389.

For the manufacture of strong, reliable screws, a fully annealed medium C steel wire is recommended. After completion of heading, thread rolling and kerfing, the screws should be heat treated. The analyses of 2 suitable wire steels is given. Ha (9)

Manufacture of Lead Covered Telephone Cable. JOHN R. SHEA (Western Elec. Co.). *Iron Age*, Vol. 127, June 18, 1931, pages 1980-1981.

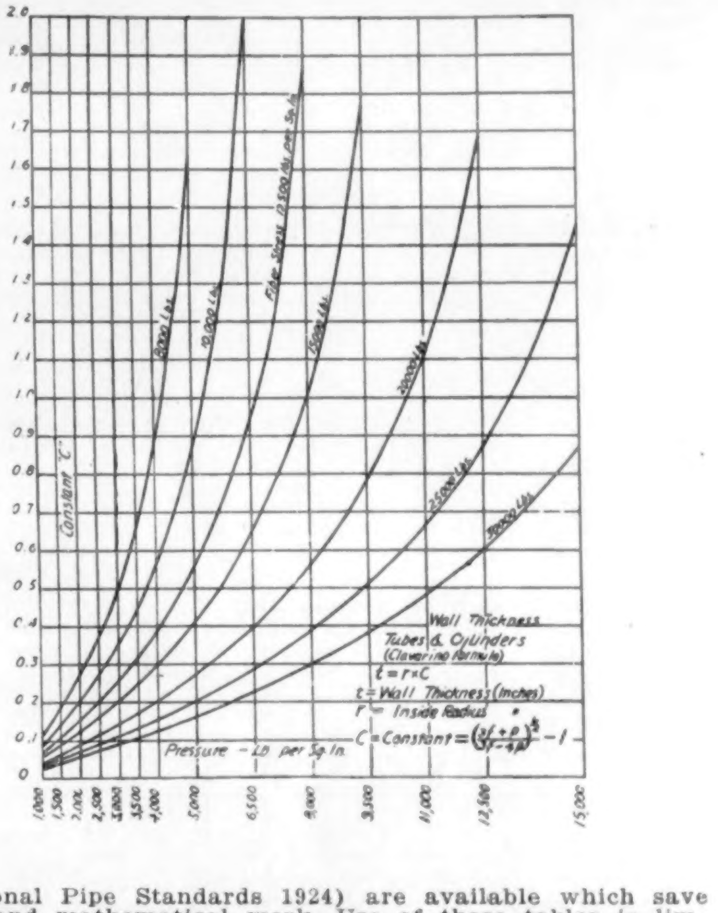
Abstract of paper read before the American Society of Mechanical Engineers, Cleveland. Discusses method of manufacture of Pb-covered, paper-insulated telephone cables at Point Breeze plant near Baltimore. See *Metals & Alloys*, Vol. 2, Nov. 1931, page 262. VSP (9)

High-Tensile Steel Used in Boilers of New Locomotives. *Boiler Maker*, Vol. 31, Feb. 1931, pages 39-40.

A silico-manganese steel with a minimum ultimate strength of 70,000 lbs./in.² is used for the boiler shell and outer fire-box wrapper sheets. Complete data of the locomotive are given. Ha (9)

Curves Aid in Design of Thick-Walled Tubes and Cylinders. F. E. WERTHEIM. *Heating, Piping & Air Conditioning*, Vol. 3, Oct. 1931, pages 850-851.

When hydraulic presses were first used, fractured cylinders were far from being unknown and, consequently, cylinder walls were made heavier when cracked cylinders were replaced. Later, when it was found that increase in wall thickness beyond certain limits did not result in a corresponding increase in strength, investigation of the strength of thick-walled tubes and cylinders began. This subject was of such importance in connection with the design of guns that many attempts were made to originate a formula. Among these formulas were those of Bix, given in the "Konstrukteur" by Prof. F. Realeaux; of Grashof, given in Unwin's "Machine Design"; of D. K. Clark, Lame, Barlow, Birnie, and Clavarina. Burr and Lanza developed formulas giving results identical with the Lamé, and Merriman developed one producing results identical with Barlow's. Inasmuch as the modified Barlow formula has found a place in the A. S. M. E. Boiler Code, this comparatively simple formula will continue to find ready acceptance. For thick-walled tubes and cylinders subjected to internal strain, use of the Clavaino formula is good practice. In order to simplify the calculations for application of this formula, tables



(National Pipe Standards 1924) are available which save time and mathematical work. Use of these tables is limited, however, because they do not apply for calculations in which the known quantities are inside diameter, working fiber stress, and working pressure. The accompanying chart has been devised for use in the solution of problems involving the Clavaino formula. In making the computations for these curves, the form of the Clavaino formula given by Merriman was used. Merriman here assumes a value of 1/3 for Poisson's ratio, while the value now generally accepted is 0.3. Because these curves are intended to cover a wide range of application, and the Merriman form has been much used for important work, the writer has given it preference in the present instance. An example to show the use of these curves follows. Given: inside diameter 16 in., working fiber stress 15,000 lbs./in.², pressure 4,000 lbs./in.² t = r x C = 8 x 0.3 = 2.4 in., say 2 7/16 in. Therefore outside diameter is 16 + 4⅞ = 20⅞ in. WAT (9)

How Shipbuilding is Tied to the Steel Industry. H. GERRISH SMITH. *Iron Age*, Vol. 128, July 16, 1931, pages 166-169.

Taken from a paper read before the American Iron & Steel Institute in New York. Deals with the history of the transformation from wooden construction, first to Fe, then to steel. At present, about 99% of a ship is steel and 1% wood. See *Metals & Alloys*, Vol. 2, Oct. 1931, page 218. VSP (9)

Some Uses of Tin in Modern Dentistry. F. C. THOMPSON. *Tin*, Sept. 1931, pages 6-8.

Tin is used to a great extent, especially in alloys of Sn and Ag for amalgam fillings. For general purposes, a composition of 67% Ag, 28% Sn, up to 4% Cu and up to 1% Zn is used. When mixing with Hg, a reaction takes place according to the formula $Ag_3Sn + 4Hg = Ag_3Hg_4 + Sn$. The filling becomes increasingly hard as this reaction proceeds because both the Ag-Hg compound and Sn are solid at ordinary temperatures. The compression strength is very great. Sn renders Au brittle, except in small amounts; a composition often used is 71.3% Au, 7.1% Ag, 9.9% Cu, 10.6% Pt and 0.83% Sn. Sn is also used in dies for swaging of crowns and bridges for which a table of compositions with their melting points is given. Ha (9)

Different Bronzes Used by the Railroad Companies (Les différents bronzes utilises par les Copagnies de Chemins de fer). R. LOISEAU. *Aciers Spéciaux, Métaux et Alliages*, Vol. 6, Apr. 1931, pages 203-208.

General consideration of 7 bronzes used by the railroad companies. GTM (9)

HEAT TREATMENT (10)

Deformations Accompanying the Heat-Treatment of Steel (Nouvelles recherches concernant les déformations accompagnant les traitements thermiques de l'acier). A. Portevin & A. Sourdillon. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 343-363; *Metallbörse,* Vol. 20, Aug. 23, 1930, page 1884.

Includes discussion and 34 figures. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 263. HWG (10)

Heating before Quenching and Drawing. *Houghton's Black & White,* Vol. 4, July 1931, pages 12-13.

The advantages of heating high speed steels in salt baths are pointed out, but the purity and homogeneity of the salt, the fluidity of the bath at working temperature and the ability to free itself from the steel are important points in obtaining uniform and efficient results. Ha (10)

Heat Treatment Fundamentals of Plain and Alloy Cast Iron. F. B. Coyle (International Nickel Co.). *Metals & Alloys,* Vol. 2, Sept. 1931, pages 120-131.

18 references are cited and 13 micrographs show structures discussed. The nature of cast iron and effects of heat on it are discussed in the light of the Fe-C equilibrium diagram. The effects of various elements on graphitization and critical ranges are shown graphically and are discussed. Constitution of Ni-cast iron is shown graphically. Use of aging and annealing operations to relieve casting strains and facilitate machining operation are discussed. Data is presented to show the relations between composition, temperatures used and the hardness obtained. The quenching and drawing of cast iron is discussed. WLC (10)

Heat Treating and Annealing Non-Ferrous Metals. A. H. Vaughan. *Fuels & Furnaces,* Vol. 9, Aug. 1931, pages 939-941.

A general discussion of the various types of electric furnaces in the heat treatment of non-ferrous metals and alloys. Ha (10)

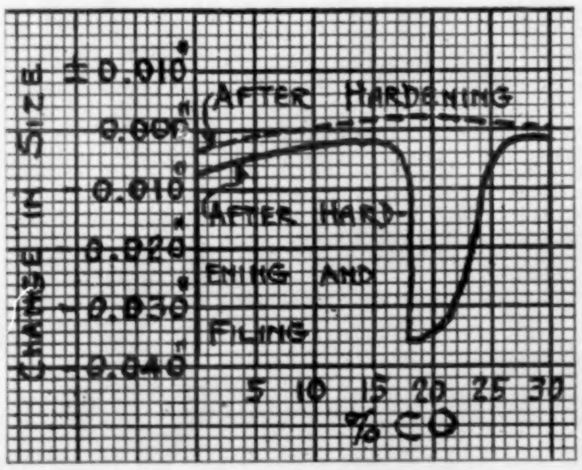
Hardening (10a)

Practical Limitations Often Prevent Perfect Hardening of Steel. Correspondence from A. Portevin, Paris, France. *Metal Progress,* Vol. 20, Oct. 1931, pages 88-89.

The writer presents graphically an analysis of the various factors effecting the proper hardening of steel, velocities available in quenching media, their effects on the properties, temperature of quench and its effects are discussed. WLC (10a)

What is a Neutral Atmosphere. Murray Winter (Winter Bros. Co.). *Metal Progress,* Vol. 20, Sept. 1931, pages 74-78.

The author reports a study of the effect of atmosphere upon the surface, surface hardness and size of small high speed steel tools. Atmospheres varying in CO content were produced from mixture of city gas and air. The CO content in the furnace was determined by analysis and controlled by a steady supply of a fixed mixture of gas and air. The graph summarizing these results shows concisely the effect of the atmosphere. At 17% CO, a good condition of tool surface is obtained but this gas analysis is very critical.



As shown, a small increase in the CO content results in decarburization until 25% CO content is reached where good tools free from decarburization and scale entirely, are obtained. With a gas mixture to maintain this atmosphere a troublesome deposit of soot is experienced. The author describes results obtained by the use of "diamond block," block of slow burning carbonaceous material which maintains an atmosphere of 28% CO in the furnace. Tools allowed to remain in such an atmosphere for as long as 20 mins. at the high temperature are not impaired in their surface quality or size. WLC (10a)

Annealing (10b)

Normalizing Steel. R. Whitfield. *Metallurgia,* Vol. 4, May 1931, pages 29-30.

Sorbitic steels have much better drawing properties than pearlitic steels. Sheets with this structure are produced by heating to the normalizing temperature and cooling at a rate sufficiently rapid to produce a sorbitic structure. A continuous furnace is best suited for this work. Mentions use of normalized sheets in stampings used in automobiles. JLG (10b)

Heat Treating Light Gray Iron Castings Decreases Difficulties in Machining. H. R. Simonds. *Foundry,* Vol. 59, Mar. 1, 1931, pages 58-62.

The annealing in continuous automatic heat treating furnaces of the Brown & Sharpe Mfg. Co., Providence, R. I., is described and illustrated. Ha (10b)

Case Hardening & Nitrogen Hardening (10c)

Nitriding for the Engineer. Oscar E. Harder (Battelle Memorial Institute). *Metals & Alloys,* Vol. 2, Sept. 1931, pages 132-142.

51 references are cited in the author's discussion of the present knowledge of the art of nitriding. Time of nitriding is discussed with modified cycles for shortening. The use of a high and a low temperature, the use of catalyzers, packing materials and continuous nitriding are discussed as they apply to the economy of the process. Cost of equipment, materials and savings through low rejects on account of warpage are referred to. Hardness obtainable with various treatments is given. Dimensional changes with time of nitriding are discussed. The protection of parts and containers against nitriding with the effect of a nitrided container on subsequent work done in it are discussed. The composition and properties obtainable from the various nitriding steels are given in tabular form. Heat treatment for core properties prior to nitriding and other preparation for nitriding are discussed. Hardness penetration curves are shown and discussed. The properties at elevated temperatures are discussed with the effect of temperature on the subsequent properties at room temperature. Creep tests, wear and abrasion resistance and corrosion resistance of nitrided steels are discussed. The stability of nitrided cases and their applications are touched upon. WLC (10c)

Surface Hardening by Nitrogen of Special Aluminum-Chromium-Molybdenum Steels on a Production Basis. W. H. Cunningham & J. S. Ashbury. *Iron & Coal Trades Review,* Vol. 123, Oct. 2, 1931, pages 492-494.

The paper explains the process of nitriding, the chemical changes taking place, testing method for hardness. It also describes the equipment necessary for nitriding on a commercial basis. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 309. Ha (10c)

Oil as a Carburizing Medium. A. J. Lindberg (Lindberg Steel Treating Co.). *Metals & Alloys,* Vol. 2, Sept. 1931, pages 106-109.

The author describes equipment for gas carburizing using oil introduced into the retort as a source of carburizing gas. The use of a diffusion period at the end of the cycle to improve the distribution of the C is discussed. WLC (10c)

Nitrided Steel and its Properties. J. H. Higgins. *Heat Treating & Forging,* Vol. 16, Dec. 1930, pages 1527-1529.

A brief outline of the process and the various steps in nitriding are given and the influence of temperature and composition of the steel are discussed. Ha (10c)

Nitrided Steel and Nitriding Furnaces (Om nitrerstål och nitrerugnar). Eimar Oehman & Erik S. Engberg. *Jernkontorets Annaler,* Vol. 115, June 1931, pages 208-230.

A description is given of the steels which are suitable for nitriding; of the pre-treatment before nitriding; the quality of the nitrided steel; and of the furnaces used. The furnace used by Luth and Rosen (Stockholm) has a volume of 1500 × 600 × 400 mm., the upper part of which is balanced by a counter-weight so that it may readily be raised or lowered. Heat is generated by electricity; the parts exposed to heat are made of fire-resistant brick; insulation is provided by 150 mm. of Mg and sil-o-cel; resistance wires are chrome nickel and 24 + 8 kw. are necessary to maintain 700° C. Ammonia is provided by rubber hose, which is not allowed to dissociate beyond 25%-30%. Control is effected by a Siemens CO_2 meter. Current is controlled by a Siemens relay which maintains the temperature within 30° C. HCD (10c)

Nitriding or Case-Hardening with Ammonia. V. O. Homerberg & J. P. Walstead. *Machinery,* Vol. 37, Oct. 1930, pages 106-108.

The general principles of this process and the physical properties of materials that can be nitrided are described. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 309. Ha (10c)

Theoretical and Practical Considerations in Case Hardening Steel by Nitriding (De teoritiska och praktiska förutsättningarna för ythärdning av stal genom nitrering). Gunnar Hägg. *Jernkontorets Annaler,* Vol. 115, May 1931, pages 183-207.

The equilibrium diagram of the systems Fe-N, its modifications in the presence of other metals and the mechanism of nitriding by NH_3 are discussed on the basis of the author's X-ray investigations (*Zeitschrift für physikalische Chemie,* 8, 1930, page 455; *Nature,* Vol. 121, 1928, page 826; Vol. 122, 1928, pages 314, 962). With the exception of Al, all metals present in nitriding steels are transition elements, the nitrides of which have a metallic character. No nitrides of Co and Ni are known, but all other transition elements used in alloy steels have a higher affinity for N than Fe, and accelerate the nitridation. This is even more true of Al. AlN, as such, is not present since Al is dissolved in the FeN. Al, Cr and Mo all suppress the γ-phase but probably do not influence the homogeneity range of the ϵ-phase to any appreciable extent. Suppression of the γ-phase is probably beneficial. A survey of the literature on the practical application of nitriding is given. HCD (10c)

Some Unusual Metallurgical Applications and Uses of Fused Salt Baths. Wm. J. Merten. *Fuels & Furnaces,* Vol. 9, Jan. 1931, pages 51-52.

The decomposition of the nitrides in cyanided parts and in arc-welded parts; blueing steel surfaces to prevent corrosion; obtaining maximum use of a metal—all by means of fused salt baths—are discussed. High temperature salt baths are also considered. Ha (10c)

Carburization of Steel with Gas. R. G. Guthrie (Peoples Gas Light & Coke Co.). *Metal Progress,* Vol. 20, Nov. 1931, pages 50-54.

The author presents reasons for the selection of gas as a carburizing medium. The presence of a sub-oxide of iron to prevent the deposition of soot is secured by proper control of the water content of the gas. The intermittent surge method of introduction of the gas is discussed as a means of controlling the case characteristics. WLC (10c)

Continuous Nitriding Process will Produce any Degree of Penetration of Hardness by Varying the Heat Cycle. R. J. Cowan (Surface Combustion Corp.). *Automotive Industries,* Vol. 65, Aug. 1931, pages 314-318.

Arrangements of successive temperature zones that may be easily controlled makes it possible to obtain different types of cases at will. Illustration of continuous nitriding furnace, together with 7 charts showing various dissociation effects, are given. A summary shows: (1) batch-type process cannot produce satisfactory work with an ammonia dissociation greater than 50%, which is due to high H concentration causing excessive decarburization: (2) continuous nitriding, where the ammonia moves along in the muffle in the same direction as the work, the danger of high H is eliminated; (3) by this process, it is possible to use fully all of ammonia admitted to system; (4) total time reduced by 1/3; (5) consumption of ammonia greatly reduced. DTR (10c)

Quenching (10d)

Dimensional Stability of Heat-Treated Aluminum Alloys. *Fuels & Furnaces,* Vol. 9, Apr. 1931, pages 433-434.

Serious dimensional changes which occur when machining operations are carried out on material quenched in cold water are reduced to relatively small proportions in "Y" alloy and duralumin by the use of boiling water as quenching medium. These alloys develop satisfactory mechanical properties when quenched in boiling water. On the other hand, they are more easily corroded than when quenched in a more vigorous medium. Ha (10d)

Drawing (10e)

Modern Rod Baking. R. S. Coulter. *Wire & Wire Products,* Vol. 6, Aug. 1931, pages 321-323.

An improved method of rod baking is described by the use of forced ventilation and a re-circulation air system. The overall thermal efficiency is 27%. In the case described, fuel costs and production were considerably improved. Ha (10e)

Aging (10f)

Duralumin. *Metallurgist,* Jan. 1931, pages 12-13.

The age hardening which is the characteristic feature of duralumin and of a number of other alloys of similar type requires a previous heat treatment which is frequently termed the "solution" treatment, since the object is to bring certain constituents of the alloy—more especially the Cu and Mg-Si compounds—as far as possible into solid solution. This treatment must be followed by quenching, usually in cold water. In the case of Y-alloy, which is used mostly for castings, quenching in hot water is used. Quenching in hot water, however, seems to render the alloy subject to intercrystalline corrosion. It is suggested that the explanation is the condition of the surface, whether under compression, free of stress, or under tension. If the latter, intercrystalline corrosion will result. The results reported by L. Pessel in *Heat Treating & Forging* of Nov. 1930 are of particular interest. He applied a salt spray corrosion test to the surface of the metal and after 30 days he could determine whether the material had been quenched in hot or cold water, the former showing a greater rate of corrosion. From the photographs given, the author draws conclusions contradictory to those of Pessel and concludes that the question must be investigated further before his results can be accepted. If Pessel's results are correct, then liability to intercrystalline attack is not in itself the determining factor in the indications of surface corrosion as revealed by the appearance of the specimens which have been exposed to the salt spray. VVK (10f)

Age-Hardening in Aluminium Alloys. *Metallurgist,* Feb. 1931, pages 30-32.

A critical review of the work of Kokubo and Honda (*Science Reports, Tohoku Imperial University,* Vol. 19, No. 4, 1930, page 366) on the mechanism of the age-hardening of Al alloys containing from 0 to 12% Cu. The criticism of the author is that the heat treatment used was unsuitable for the purpose and that the conclusions arrived at as original are practically identical with those of Gayler and Preston (*Journal Institute of Metals,* Vol. 41, 1929, page 191). VVK (10f)

Pressure-Ageing of Duralumin. *Metallurgist,* Sept. 1930, pages 136-137.

A review of the work of L. Pessel in *Industrial & Engineering Chemistry* for July 1930. See *Metals & Alloys,* Vol. 2, Sept. 1931, page 177. VVK (10f)

The Course of Aging of a Few Aluminum Sand-Cast Alloys. (Ueber den Verlauf der Alterung bei einigen Aluminum-Sand-guss-Legierungen.) W. Saran. *Zeitschrift für Metallkunde,* Vol. 23, Jan. 1931, pages 32-33.

The aging of 3 Al alloys is studied by means of the elastic limit (0.01 or 0.03%) and Brinell hardness. The first alloy contained 9.7% Zn, 2.1% Cu, 1.28% Fe, 0.25% Si, 0.23% Mg; the second an (American) alloy with higher (but unstated) Zn content and with 8% Cu, 0.2% "Y," Fe and Si normal; the third an alloy with 15% Zn, 2% Cu, 0.22% "Y," Fe and Si normal. The first alloy was sand (10-11% moisture) cast from 680° C., and annealed at 490° C. and quenched in water. A curve of the variation in Brinell hardness with time at room temperature is given. This shows a maximum at 12 days, a following minimum and then a slow increase with time. The points scatter showing a certain periodicity which may be related to the night-day temperature change. The second and third alloys were also sand (6% moisture) cast and the aging followed by Brinell hardness and elastic limit. The elastic limit increases about 1.7 kg./mm.^{2} after 21 days for both alloys; the Brinell hardness shows only a slight increase. Because of the special addition "Y," it is not necessary to heat-treat the alloy after casting in order to induce aging. The aging of these 2 alloys is approximately proportional to the time. RFM (10f)

JOINING OF METALS & ALLOYS (11)

Soldering, Brazing and Riveting Sheet Metals. Part III. Riveting. *Sheet Metal Industries,* Vol. 4, Oct. 1930, pages 447-449; Nov. 1930, pages 541-547.

The applications of riveting, the types of rivets used, the types of joints, the methods of finishing rivets and the proportioning of riveted joints is discussed. Tables for single-riveted and double-riveted lap joints give proper rivet diameters, lap, pitch, and percentage of strength for riveted joints in sheet metal work up to ⅛ in. thickness. Riveting of Al is discussed briefly. The capabilities of 2 riveting machines are set forth—they are the Hann riveting machine and a small, high speed hammer. AWM (11)

Brazing (11a)

Silver Brazing of Monel Metal and Nickel. *Inco,* Vol. 10, No. 4, 1931, pages 26-27.

Ag solders are alloys of Ag, Cu and Zn with or without other metals in small amounts. The main characteristics of Ag solders are: melting points from 1325°-1600° F.; free flowing (they penetrate almost instantly); joints have a tensile strength of 40,000 to 60,000 lbs./in.^{2}; almost unlimited corrosion resistance; neat joints. Instructions for the use of Ag solders and fluxes for it as well as the precautions necessary are given. Ha (11a)

Making Joints with Electric Brazing Tongs. *Machinery,* Vol. 38, Sept. 1931, pages 23-24.

A little brazing transformer to heat the ends can be used for joining Cu, Ni, Ag, steel and their alloys. 3 different Ag fluxes with melting points of 1337°, 1355° and 1526° F. are used. Ha (11a)

Silver Brazing of Monel Metal and Nickel. *American Metal Market,* Vol. 38, Apr. 2, 1931, pages 3, 5.

Includes discussion. Gives definite details and characteristics of silver solders. Composition, penetration, strength, ductility, corrosion resistance. Expert directions for brazing include cleaning, fitting, fluxing, preheating and soldering. Also typical applications. DTR (11a)

Brazing Alloy with Low M. P. *Brass World,* Vol. 27, Aug. 1931, page 186.

"Sil-Fos" is an alloy containing a small proportion of Ag and flowing freely at 1300° F. It has free flowing properties with deep and quick penetration. It is manufactured by Handy & Harman, N. Y. C. "Sil-Fos" may be used for joining brass, bronze, nickel, nickel-silver, extruded brass and bronze, monel metal and other metals and alloys fusing above 1300° F. WHB (11a)

Welding & Cutting (11c)

Investigations on the Gas Fusion Weldability of Chrome Molybdenum Alloy Steels for the Construction of Aeroplanes (Untersuchungen über die Gasschmelzschweissbarkeit von chrommolybdänlegierten Stählen für den Flugzeugbau). K. L. Zeyen. *Krupp'sche Monatshefte,* Vol. 12, Aug.-Sept. 1931, pages 214-223.

After a review of the literature on chrome-molybdenum alloy steels for aeroplanes, the results of experiments made on thin sheets of such steels with different welding wires are described. Instead of the American steel (SAE No. 4130 with 0.25-0.35% C and 0.8-1.1% Cr), it seems more advisable to use a steel with less C (0.2-0.25%) and a higher Cr content (1.3-1.5%) to obtain a better weldability with increased hardness. The unalloyed welding wires gave, in all cases, lower values of strength. Ha (11c)

The Gas Supply of Welding Shops (Aus der Praxis der Gasversorgung von Schweisswerkstätten). From the experimental laboratory of the Autogen Works. E. Zorn. *Autogene Metallbearbeitung,* Vol. 24, July 15, 1931, pages 207-215.

A survey of the means and arrangements for the storage of carbide the storage of acetylene, and pipe lines for acetylene. A special chapter treats of acetylene in flasks for which the manufacturers prescribe definite rules. The containers and reduction valves for the compressed O are also discussed and practical suggestions are given. Ha (11c)

Arc Welding. E. J. Tangerman. *American Machinist,* Vol. 75, July 2, 1931, pages 2-6.

The technique, equipment and effect of arc welding, both manual and automatic, of machine structures is discussed at length. Ha (11c)

Automatic Oxy-Acetylene Cutting in Machine Building. D. E. Roberts. *Machinery,* Vol. 37, Nov. 1930, pages 161-164.

Demonstration of the application of machines having automatically guided blowpipes which cut steel billets and plates to shape in any thickness up to 15 ins. Ha (11c)

The Influence of Small Additions to the Weld Rods on the Welding of Copper. (Ueber den Einfluss von geringen Zusetzmengen in den Schweissdrähten auf die Schweissung des Kupfers.) W. Geldbach. *Autogene Metallbearbeitung,* Vol. 24, Nov. 1, 1931, pages 319-331; Nov. 15, 1931, pages 335-345.

A systematic and comparative investigation on the influence of additions of P, Al, Be, Mg, Li, Ti, V, Si, Mn, Cr, Zn, Cd, Ni, Sb, As and Ag in the welding wires on the weldability and fluidity of Cu was made. The "fluidity" is defined by the physical properties of the melt, in particular by the surface tension and viscosity. 2 principal types are found: (1) very mobile fluidity (produced, for instance, by the addition of P) and, (2) viscous fluidity, for instance, wires containing Al. Fluidity of type (1) was obtained by wires containing high percentages of P and Li. Type (1a) was obtained by Ti, Sb, As, Zn, Ni, Ag. Type (2) was obtained by Be, Al, Mg, Si, Mn, Cr and Cd. Type (1a) was produced by a suitable flux —usually containing boric acid (B_2O_3)—to type (2). The tests are described at great length. For details, the paper must be consulted. 60 references. CO_2 Plant Manufactured by Welding in Melbourne. *Welder,* Vol. 2, Aug. 1931, pages 15-18; Vol. 3, Sept. 1931, pages 25-28.

The chimney 50 ft. long, 3 ft. in diameter was welded in 3 sections of 5/16 in. and 1/4 in. plate; weight 215 tons. Absorber towers and heaters, gas tank of 10 ft. diameter and 9 ft. deep were also welded. Ha (11c)

Arc-Welding of Locomotive Frames. J. M. Vossler. *Welding,* Vol. 2, July 1931, pages 446-447; Aug. 1931, pages 511-513.

Autogenous welding in boiler repairs, locomotive cylinders, reclamation of car parts, reclamation of superheater units and boiler flues, arc welders' tools and oxy-acetylene welders' service trucks are discussed and described. Some suggestions as to preparation and procedure are given. Ha (11c)

Welding in the Piping Industry. John Zink. *Industry & Welding,* Vol. 2, Oct. 1931, pages 10-13.

General remarks on joining pipes by welding, the factors of design and cost estimating, workmanship. All of these contribute, both technically and commercially, to success. Ha (11c)

Fusion Welding Specifications for Steel and Wrought Iron Pipes. John H. Zink. *Welding,* Vol. 1, Dec. 1930, pages 975-978.

The fusion welding specifications adopted by the Heating & Piping Contractors Association are complete as to workmanship, design and materials. Discussion and illustrations are included. Ha (11c)

Testing Welded Construction during Production. *Chemical & Metallurgical Engineering,* Vol. 37, Oct. 1930, pages 609-610.

Deals with procedure at the Barberton, Ohio Works of the Babcock & Wilcox Company. Contains same information as "Develops New Technique in Electric Arc Welding," by J. D. Knox in *Steel,* Vol. 87, Oct. 9, 1930, pages 64-65. See *Metals & Alloys,* Vol. 2, Sept. 1931, page 181. MS (11c)

Review of Welding Methods and the Testing of Welded Seams with Special Consideration of Welding in Boiler Making (Uebersicht über die Schweissverfahren und die Prüfung der Schweissnähte mit besonderer Berücksichtigung der Schweissung im Dampfkesselbau). K. L. Zeyen. *Krupp'sche Monatshefte,* Vol. 12, June 1931, pages 121-139.

A comprehensive survey of the various methods of pressure welding and fusion welding, of which only the latter is of im portance in steam welding; i. e. gas welding and electric arc-welding. The weldability of the steel and the influence on it of the composition, the polarity of the zones with explanatory photomicrographs, costs for gas and electric welding as function of the thickness of the boiler plate, testing methods of samples and of the finished pieces and testing apparatus are discussed at great length. 23 references. Ha (11c)

Welding in the Locomotive Boiler. James M. Vossler. *Welding,* Vol. 2, Oct. 1931, pages 679-681; Nov. 1931, pages 731-733, 743-744.

Success of metallic arc welding of firebox sheets depends on proper preparation of edges, cleaning preparatory to welding, and proper welding procedure to take care of expansion and contraction. Angle of opening for butt welds should be between 75° and 90°. Opening at the apex of the Vee should be 3/32-1/8". The step-back method should be followed in welding. A modified double Vee joint is recommended and illustrated. Ha+TEJ (11c)

Tests of Welds. Wilbur M. Wilson. *University of Illinois Engineering Experiment Station Circular* No. 21, Nov. 1930, 37 pages; *Canadian Engineer,* Vol. 59, Sept. 16, 1930, page 332.

The investigation pertains only to hand-welding of the relatively thin steel plates used in the fabrication of storage tanks for oil and water systems. The objects of the investigation were to determine the physical properties of a weld-rod after it had been deposited in a weld, the relative merits of various types of welds for thin plates, and the relative merits of various types of weld-rods. Of the welds tested, the V type seems to be the best for making butt-joints in ½-in. plates. In the study of various types of weld-rods, 36 specimens were tested that had been welded by the same workman, a journey-man welder employed by the Chicago Bridge and Iron Works; 6 specimens were made from each of 11 kinds of rods. The weakest specimen developed 46,000 lbs./in.^{2} The lowest average for any one set of 6 specimens made from the same kind of rod was 50,500 lbs./in.^{2} The specimens received no heat treatment after the welds were made. Specimens made from rods designed to produce a reducing atmosphere over the molten metal had a strength of an average of 60,000 lbs./in.^{2} The data indicate that a rod designed to produce a reducing atmosphere over the molten metal may be, but is not necessarily, superior to an uncoated rod. The strength of welded specimens made from uncoated rods was 57,500 lbs./in.^{2} when the beads were laid longitudinally with the specimens, and 43,300 lbs./in.^{2} when the beads were laid tranversely to the specimens. VVK+WAT (11c)

Welding with Atomic Hydrogen. J. F. SPRINGER. *Modern Machine Shop,* Vol. 4, Nov. 1931, pages 30-36, 73.

The principle and the action of atomic hydrogen welding is described, i. e., the breaking up of ordinary H by the electric arc into atomic hydrogen which combines again at a nearby point and creates a flame of about 4000° C. Because of its protection against outside contamination, very ductile welds are produced. Steel as well as aluminum can be welded. A number of applications are described and illustrated. Ha (11c)

Replacement of Castings with Welded Steel Plate. G. D. SPACKMAN. *Welding,* Vol. 2, Oct. 1931, pages 673-674.

Because it is homogeneous, uniform ,and its properties known, steel properly made, rolled, cut, formed and welded, is superior in the construction of machinery and equipment parts. TEJ (11c)

Welding Research. H. L. WHITTEMORE. *Industry & Welding,* Vol. 2, Oct. 1931, pages 7-9, 23.

General remarks on the way in which practical research should be carried out. The most important feature is to invariably keep complete records of whatever has been done. Ha (11c)

Arc-Welding the Stainless Alloys. V. W. WHITMER. *Welding,* Vol. 2, July 1931, pages 457-464.

The expansion, fixtures and electrodes and the characteristics of alloy chrome-nickel steels in welding are discussed and illustrated in micrograms. The physical properties of the steels Enduro AA and KA2S are given in a table. Methods of testing and test results are explained and illustrated. For welding these alloys, a coated rod is recommended. Ha (11c)

Factors Affecting the Weldability of Steel. W. E. STINE. *Journal American Welding Society,* Vol. 10, Sept. 1931, pages 22-26; *Electrical World,* Vol. 98, Oct. 26, 1931, pages 786-788.

Paper presented before the Fall Meeting of the American Welding Society in Boston, Sept. 1931. Investigation of causes of slag holes and gas holes in arc welds. Aluminum oxide, or any other non-metallic inclusion in steel which has its melting point between the melting point and boiling point of steel, will cause slag holes or pits in the weld metal of electric arc welded steel unless it is fluxed with some other material which lowers its freezing point below that of steel. Al, Si, Mn or any other deoxidizers having gas solvent properties, which are present in excess of the quantity necessary for chemical equilibrium with the O present in the steel at a temperature slightly above the temperature of solidification, may cause the formation of gas holes in the weld metal of electric arc welded steel. Curves are reproduced which indicate Al, Si and Mn content of steel of optimum arc welding characteristics. 7 references are given. TEJ+WHB (11c)

Automatic Carbon-Arc Welding (Selbsttätige Kohle-Lichtbogenschweissung). S. SANDELOWSKY. *A. E. G. Mitteilungen,* Nov. 1931, pages 656-663.

The carbon-arc welding differs from metal wire arc welding principally in that the sheets to be welded are joined with as little additional material as possible merely by welding the edges together (butt welding). The carbon arc is, therefore, usually used for edge welding; several methods are illustrated. An automatic welding machine for this purpose has been developed which is described fully and curves taken from tests made on sample rods of different thicknesses are reproduced. The advantages of this simpler procedure which does not require as elaborate preparations as metal arc welding are noted. Ha (11c)

Electrically Welded Steel Water Pipe. W. H. POWELL. *Canadian Engineer,* Vol. 59, Nov. 4, 1930, pages 599-604.

50,000 ft. of electrically-welded pipe were furnished the Greater Vancouver Water District in 1929 and 1930. The details of its manufacture, testing and suggestions for shop practice are given. VVK (11c)

Welding Structural Steel Buildings. FRANK P. MCKIBBEN. *Canadian Engineer,* Vol. 61, July 14, 1931, pages 15-18, 52.

The details of the erection of the 19-story, all-welded office building of the Dallas Power & Light Co., Dallas, Texas, are given, including the qualifications and requirements of welders. VVK (11c)

Jigs of Arc-Welded Steel. H. F. KNEEN (Lincoln Electric Co.). *American Machinist,* Vol. 74, Apr. 30, 1931, page 689.

Largely pictorial. Gives a few suggestions as to jigs which can be arc-welded. RHP (11c)

Flame-Cuts in Spring Steel (Brennschnitte an Federstahl). ALEX. MATTING. *Autogene Metallbearbeitung,* Vol. 24, Sept. 15, 1931, pages 277-280.

Numerous tables and microphotographs of etching illustrate the tests made on hardened and unhardened spring steels by manual and by machine cutting with a flame. An influence can be seen clearly; but a subsequent heating or hardening removes this influence. The zone in which an influence can be found does not need to be removed as long as the cutting edges are not subject to particular stresses. Machine cutting proved to be more advantageous than manual cutting. Ha (11c)

Welding Solves Another Problem. FRANK P. MCKIBBEN. *Journal American Welding Society,* Vol. 10, Sept. 1931, pages 47-49.

Paper presented before the Fall Meeting of the American Welding Society in Boston, Sept. 1931. Description of a unique remodeling problem which consisted of the transference of a large load from an existing main building column to a new girder, removal of the lower story's length of column, the abatement of noise and avoiding subsidence of existing construction. TEJ (11c)

Electric Welded Steel Floor Construction. LEE H. MILLER. *Canadian Engineer,* Vol. 58, June 24, 1930, pages 701-702.

A paper presented before the American Welding Society. See *Metals & Alloys,* Vol. 1, Oct. 1930, page 801. VVK (11c)

Welded Buildings and Bridges Erected in the United States. FRANK P. MCKIBBEN. *Welding,* Vol. 2, Sept. 1931, pages 612-618.

A list of 46 partially or wholly welded bridges and 183 partially or wholly welded buildings in the United States. TEJ (11c)

The Manufacture of Machine Parts for Aviation Viewed from Safety Standpoint. (Le faconnage des éléments de machines de la construction aéronautoque considére au point de vue de la sécurité.) J. Androuin. *Revue de Métallurgie*, Vol. 28, Oct. 1931, pages 575-580.

Attention is called to the proper care to be exercised in finishing parts and their jointing so as to prevent localized stresses. Hand work must be eliminated as far as possible. JDG (11c)

Welded Boiler. J. C. Hodge. *Boiler Maker*, Vol. 31, Jan. 1931, pages 2-8.

Fusion-welded seams have been accepted for 24 boilers for new scout cruisers of the U. S. Navy. Tests of sample welds are described and macrographs and micrographs show conditions of the weld which are acceptable and those which are not acceptable. The physical and chemical welding characteristics specified by the Navy and as obtained by Babcock & Wilcox are tabulated. Ha (11c)

Welding Allegheny Metal. G. Van Dyke. *Machinery*, Vol. 37, July 1931, pages 875-877; *Sheet Metal Worker*, Vol. 22, Aug. 21, 1931, pages 497-498.

Allegheny metal is a chrome-nickel iron alloy containing approximately 18% Cr, 8% Ni and small amounts of Mn and Si. The C in this alloy will vary from 0.15 to 0.06%, depending upon the class of work for which it is to be used, and the method employed in fabricating it. This particular type of alloy lends itself readily to welding by the electric, gas or spot processes. The 18-8 type of stainless steel finds wide application not only because of its weldability, but also because it presents great resistance to a large variety of corrosive attacks. The first consideration in gas-welding Allegheny metal is to get the proper mixture of acetylene and O. If an excess of O is used, it will burn up or oxidize a considerable portion of the Cr, and this not only changes the analysis of the metal, but also produces oxides of Cr which will cause the metal to boil and result in welds that are porous and of low corrosion resistance value. If an excess of acetylene is used, the molten metal will absorb a certain amount of gas, and the C content of the weld will thereby be raised. This increase in C content is very detrimental to the corrosion resistance and produces a brittle weld. Evidently an exactly neutral flame with an excess neither of acetylene nor oxygen would be desirable and, if it were possible to produce such a flame, it would probably be ideal. The flame should be adjusted so as to give a very slight excess of acetylene. In gas-welding this alloy, the torch should be held as close to the metal as possible, so as to push the flame down into the weld; and the rod would be held above the weld so that it will melt and drop down as the welding proceeds. Puddling should be avoided, as it tends to produce a porous weld. Ha (11c)

Arc Welding Everdur. T. E. Jerabek. *Boiler Maker*, Vol. 31, Mar. 1931, pages 68-69.

Everdur, a Cu-Si-Mn alloy with qualities equal to steel and able to resist corrosion and chemical action, can be arc-welded. A metallic electrode ⅛ to 3/16 in. thick of similar composition to the parent metal is used with a current of 90-160 amp. The arc must be held somewhat longer than is common in the arc-welding of rolled steel. Micrographs illustrate the quality of the welds which are made. Ha (11c)

Development in Arc Welding Methods. *Canadian Engineer*, Vol. 59, July 22, 1930, pages 169-170.

Late developments in arc welding are reviewed. The advantages of welding for machinery design and building construction are enumerated. VVK (11c)

Fusion Welding as Applied to Pressure Vessels. *Boiler Maker*, Vol. 31, Sept. 1931, pages 242-244.

The Chicago, Burlington & Quincy Railroad decided to use welded construction because of the high maintenance cost of riveted seams on their tie-treating retorts. Ha (11c)

Oxwelding for Overland Pipe Lines. *Canadian Engineer*, Vol. 59, Nov. 25, 1930, pages 661-666.

Graphic Formula Finds Proper Welding Steel. *Welding*, Vol. 2, June 1931, page 394.

An equilibrium diagram was developed by Wm. Stine of the Lincoln Electric Co., Cleveland from an investigation of the causes of the difference (sometimes inexplainable) in 2 similar welds. It is seen from this diagram that, for a certain percentage of C, the amount of Si and Mn and, eventually, Al can be taken to obtain the correct proportion of elements in steel for welding. Ha (11c)

Metallic-Arc Method of Pipe Making. *Iron & Coal Trades Review*, Vol. 123, Oct. 16, 1931, pages 573-574.

Description of an automatic welding machine installed at the South Durham Steel & Iron Co., England. It can accomodate 30 ft. pipes and tanks 9 ft. high. Ha (11c)

Electric Welding Steel Tubing. *Boiler Maker*, Vol. 31, Mar. 1931, page 71.

The Johnson process and equipment used by the Steel & Tubes Inc., Cleveland, is described. Tubing up to ¼ in. thick can be welded. The process consists of feeding large coils of flat steel stock into the forming rolls to be formed cold into a tube. This passes directly under the electrodes where fusion takes place without the addition of foreign materials at a speed of approximately 80 ft. of tubing/min. The welding burr is eliminated and the weld is almost imperceptible. When operated at full capacity, over 1200 kilowatts are concentrated continuously in a spot not larger than the eraser on a pencil. Ha (11c)

Proposed Specifications for Fusion Welding *Boiler Maker*, Vol. 31, Mar. 1931, pages 79-80, 84.

Reprint of revisions of the Boiler Code Committee. Ha (11c)

Gas Welding of Alloys. *Welding*, Vol. 2, June 1931, pages 372-376.

Procedure-control methods used for oxy-acetylene process of welding ferrous and non-ferrous metals are described briefly and illustrated. The particular precautions necessary in using some materials are pointed out. Ha (11c)

Electric Welded Steel Pipe Lines. F. W. Hanna (Chief Engineer, East Bay Municipal Utility District, Oakland, Calif.). *Journal American Water Works Association*, Vol. 23, June 1931, pages 785-792.

A detailed description of the electric welded Mokelumne pipe line comprising 58.6 miles of 65", 13.9 miles of 63", 9.1 miles of 61" and 1.1 miles of 54" internal diameter pipe made of steel plates of ⅜, 7/16, and ½" thicknesses. VVK (11c)

Automatic Welding Thin Walled Cylinders. W. A. Maddocks. *Welding*, Vol. 2, Nov. 1931, page 744.

By swiftly flattening the cylinder previous to welding by an attachment to the automatic welder, the cylinder assumes its true shape after the metal has cooled. Ha (11c)

Arc-Welding a Steel Factory Building. H. B. Hanna. *Canadian Engineer*, Vol. 59, Dec. 23, 1930, pages 727-730.

A detailed description of the all-welded construction of the switchboard building of the Peterborough plant of the Canadian General Electric Co., Ltd. VVK (11c)

Autogenous Welding of Lead and its Alloys—Ancient and Modern. E. B. Partington. *Welding Engineer*, Vol. 28, Oct. 1931, pages 304-310.

Paper read before the members of the Institute of Welding Engineers, Oct. 15, 1931. The author gives a brief history of the early manufacture of lead from the ore, its uses and characteristics. Various methods of lead-burning are described and their relative merits discussed. Physical properties and welding qualities of some alloys of lead with Cd, Sb and Sn are mentioned. The author enumerates various lead-burning applications and gives data on gas consumption. TEJ (11c)

Investigations of Electric Arc Welding with Metallic Electrodes (Untersuchungen über die elektrische Lichtbogenschweissung mit metallischen Elektroden). *Die Schmelzschweissung*, Vol. 9, Sept. 1930, page 201.

Tests were made with iron electrodes covered with a mixture of graphite and carborundum in varying amounts and steel sheets welded with them. The welds were then analyzed chemically and the hardness tested. Pure graphite cover and the one with 90% graphite gave the best hardness, Brinell 420, with a minimum hardness of 145 at 40% graphite, rising again to 250 at pure carborundum. With an addition of barium carbonate of 1%, it was not necessary to preheat, but the welding took a little longer when connected to the negative pole. Ha (11c)

Arcogen, a New Combined Autogenous-Electric Welding Process (Arcogen, ein neues kombiniertes autogen-elektrisches Schweissverfahren). *Automobil-technische Zeitschrift*, Vol. 34, Sept. 10, 1931, page 557.

A short description of this new method of the I. G. Farbenindustrie A.G. which has been treated more in detail in *Metals & Alloys*, Vol. 2, Mar. 1931, page 70. Ha (11c)

New Pipe Mills at McKeesport Works of National Tube Co. Sidney G. Koon. *Iron Age*, Vol. 127, May 7, 1931, pages 1502-1507.

Describes the new electrical welding pipe department. This plant makes pipes from steel plates in lengths of about 40 ft. Electric welding is done in a battery of 30 machines. Capacity is about 4 miles of pipe/day. VSP (11c)

The Theory of Welding Stresses (Etwas über die Theorie der Schweisspannungen). *Schmelzschweissung*, Vol. 10, Sept. 1931, pages 223-226.

Theoretical treatment of determining the stresses in different kinds of welds. Ha (11c)

The Future of Welding in the Aircraft Industry. *Welding*, Vol. 2, Sept. 1931, pages 605-607.

The aircraft industry now thinks in terms of welding. This is due to the success attained in the past few years with various kinds of welded structures. This writer states that oxy-acetylene welding has been given preference because it is more universally adaptable to the fabrication of the several types of approved aircraft joints. Manufacturers of gas welding equipment, therefore, have been active in developing light weight, reliable and efficient equipment for the airplane factory. This writer also claims that it is generally conceded that a longer training period is required, therefore causing fewer operators to qualify than in the case of the arc welding process. He concludes, however, that the development of apparatus which will permit easier and better control of the arc probably will lead to more extensive applications of this arc method to aircraft work in the future. Ha (11c)

Welding Automobile Wheels. C. L. Eksergian. *American Machinist*, Vol. 75, Sept. 17, 1931, pages 459-463.

As a process in the manufacture of automobile wheels, welding has made considerable gains. However, with the exception of one wire wheel in which the spokes are welded, it only has been at a relatively recent date that welding has been utilized to any extent. The fact that welding has proven itself to be perfectly dependable even though subjected to the high loads carried by wheels at last has won the confidence of the dubious. This fact, together with the manufacturing economies effected, has justified its pioneers and will serve, no doubt, to widen its adoption. Perhaps the most widely used types of welding in wheel practice are the flash or the butt weld. Practically all rims and felloe bands employ circling. This practice has been in effect for a great number of years, hence welding of that character may be regarded as being quite orthodox. Although the terms "flash" and "butt" welding are often interchanged, actually these 2 forms of welding possess distinct characteristics and function of operation. It so happens, however, that in many instances the actual welding operation amounts to a compromise between a true butt and a true flash method. For this mixed form of welding either term is probably equally appropriate. Ha (11c)

Welding Practice in Tramway Concerns. *Welder*, Vol. 3, Oct. 1931, pages 4-7.

Repair of parts of equipment and rails is described. Ha (11c)

Welding of Lead not Difficult. *Sheet Metal Worker*, Vol. 22, Oct. 30, 1931, pages 621-622.

Some practical suggestions are given for the use of the blow pipe for gas welding of Pb. Ha (11c)

WORKING OF METALS & ALLOYS (12)

Melting & Refining (12a)

The Diminishing of Non-Metallic Inclusions in Steel by Adding Zirconium (Die Verminderung nichtmetallischer Einschlüsse im Stahl durch Zirkonzusatz). W. Zieler. *Archiv für Eisenhüttenwesen,* Vol. 5, Sept. 1931, pages 167-172.

The paper deals first with a paper by A. L. Field, *Transactions American Institute Mining & Metallurgical Engineers,* Vol. 69, 1923, pages 848-894, on the effect of Zr upon the contents of O, Ni and S in steel. The second part gives the results of the author's own investigations on a Cr-Mo steel, the charges of which had in part been treated with Zr-Si. The effect of Zr was studied by counting the inclusions in polished specimens taken from various parts of the rolled billets. Since Zr has a stronger deoxidizing effect than Si and eliminates the dangerous effect of S by the formation of ZrS, it essentially decreases the non-metallic inclusions of steel. The production costs of steel do not increase very much by the addition of Zr. GN (12a)

Open Hearth Furnace Practice (La pratica del Forno Martin). F. Fiorelli. *La Metallurgia Italiana,* Vol. 23, Oct. 1931, pages 955-963.

By sketches, the furnace ports and gas circulatory systems of several types of open hearth furnaces, including the Terni furnace, are described. HWG (12a)

Characteristics of Rimmed Steel. E. C. Bitzer. *Blast Furnace & Steel Plant,* Vol. 19, Feb. 1931, pages 249-251; Mar. 1931, pages 415-417, 422.

Rimmed steel is called a product of the basic open-hearth and acid Bessemer processes and is a steel partially deoxidized, either in the furnace or in the ladle, and poured in this condition. The predominant reaction goes on between dissolved ferrous oxide and C as follows: $FeO + Fe_3C \rightleftharpoons 4\,Fe + CO$. The range of analysis of this steel is usually 0.02-0.20% C, 0.15-0.50% Mn, 0.025-0.050% S, any desired amount of P and a trace of Si. The production and treatment is described in detail. A list of references is added. Ha (12a)

Fluorspar in the Open-Hearth Slag. H. L. Geiger. *Blast Furnace & Steel Plant,* Vol. 19, Mar. 1931, pages 412-414.

The formation of silicate, phosphate and tapping slags is explained. The investigation shows that no fluorspar, but iron oxide is the actual thinning agent of the slag; the fluorspar acts only indirectly as the medium for setting up an unstable condition of the slag which can only be neutralized by the addition of iron oxide obtained from the bath. 9 references. Ha (12a)

Steelmakers Face New Era of Steel Cleanliness. *Steel,* Vol. 88, Jan. 1, 1931, page 290.

The deoxidation of steel with Mn-Si alloys, the mechanical control of combustion and the study of the influence of slag composition promise to produce steel of exceptional cleanliness. The application of the electrolytic method for extracting non-metallic inclusions from steel offers a rapid and economical means for determining the number, volume and character of the impurities present. Also, quick analytical methods are now available for determining the physical properties of slags during the workdown of open-hearth heats. JN (12a)

Aluminum Melting Furnace of Large Capacity Fired by Solid Fuel. Rob. J. Anderson. *Fuels & Furnaces,* Vol. 9, May 1931, pages 583-586, 618; June 1931, pages 697-700; July 1931, pages 799-802; Aug. 1931, pages 933-936.

The article describes and gives the design of an aluminum melting furnace of the open flame stationary hearth type which is fired by coal or coke. This type is used for a number of melting operations, of scrap, melting, remelting, alloys for casting, etc. They range from 2000 to 50,000 lbs. The use of coke is said to give a better quality of metal as the quantity of gas taken into solution by the metal is considerably less when melted in an open flame, coke fired furnace. The technique of handling large quantities of liquid Al metal and methods and equipment in foundry and rolling mill are discussed at length. Ha (12a)

The Use of Strontianite in Basic Open Hearth Furnaces (Emploi de la strontianite dans le four Martin Siemens basique). *Journal du Four Electrique,* Vol. 40, Mar. 1931, page 96.

The addition of mineral strontianite to the slag of hot working basic open hearth furnace is claimed to reduce the S content of the metal to ½ provided the original content of it is high enough to give in the final product not less than 0.03% S. JDG (12a)

The Deoxidation of Copper. *Metallurgist,* Dec. 1930, pages 182-183.

The work of Schumacher, Ellis and Eckel (*American Institute Mining & Metallurgical Engineers Technical Publication* No. 240) on the use of Ca as a deoxidizer for Cu and (*Metals & Alloys,* Vol. 1, Sept. 1930) the use of Zn, Be, Ba, Sr and Li for the same purpose is reviewed with the following comment. "In considering these results from a quantitative standpoint, it must be borne in mind that the published data apply only under the conditions of melting employed by the authors, since the oxidation of the metal and consequently the amount of deoxidiser added will vary with the melting and casting conditions, and if certain precautions are used to limit oxidation as far as possible, the quantity of deoxidiser to be added will of necessity be smaller. Recent research has also pointed out that it is possible for oxygen to co-exist in copper with a deoxidising element such as phosphorus, and that in all probability an equilibrium is set up between oxygen and the deoxidising element, so that the ultimate concentration of the reacting elements will depend on various conditions such as time of reaction and their initial concentration. The results are complicated by the fact that the copper is continually absorbing oxygen to an extent depending on the nature of the surrounding atmosphere, and on the precautions, if any, taken to exclude that element. The application of the quantitative results must, therefore, be confined to the particular conditions under which the data were obtained." VVK (12a)

Casting & Solidification (12b)

The Solidification and Crystallization of Steel Ingots: The Influence of the Casting Temperature and the Undercooling Capacity of the Steel. Bernhard Matuschka. *Iron & Steel Institute, Advance Copy* No. 12, Sept. 1931, 16 pages.

Discusses the mechanism of solidification. The external conditions are governed by the rate of heat extraction by the mold. The internal conditions are set by the nature of the alloy being cast. The course of solidification was studied by dumping the molten alloy from a mold after it had remained in the mold for a given length of time. Macrographs of etched and of fractured sections illustrate the effects of different casting conditions on the primary structure. The factors that govern columnar crystallization are discussed in detail. JLG (12b)

Permanent Mold Casting of Aluminum Alloys. J. B. Nealey. *Machinery,* Vol. 37, Oct. 1930, pages 100-102.

The advantages of using permanent molds rather than sand castings or die-castings are: a wider range of alloys can be used as pouring is done by gravity and higher temperatures can be used, as is required by metals melting in the neighborhood of 2000° F. The physical properties of permanent mold castings and the alloys used for them, the materials used for permanent molds, construction of melting furnaces and annealing and finishing methods are discussed in general. Ha (12b)

Die Castings may Now be made of Brass. L. H. Morin (Doehler Die Casting Co.). *Iron Age,* Vol. 127, May 7, 1931, pages 1522-1523.

The commercial production of brass die castings embraces the following conditions: (1) handling of the metal at the lowest possible temperature and (2) the removal of the finished casting from the die in the shortest possible time. VSP (12b)

Casting Guns by the Centrifugal Process. T. C. Dickson. *Iron Age,* Vol. 127, June 4, 1931, pages 1816-1818.

Taken from a paper read before the American Society for Steel Treating. Includes part of discussion. Describes method of procedure and gives the metallurgical advantages obtained. Shows how a moderate segregation in the resultant material is of benefit in meeting service requirements. See also *Metals & Alloys,* Vol. 2, Nov. 1931, page 269. VSP (12b)

Casting under Pressure (La coulée sous pression). *Revue Fonderie Moderne,* Vol. 25, July 25, 1931, pages 273-275.

A brief discussion and description of the principles, the most suitable metals (alloys of Sn-Pb, Zn, Al and, lately, brasses) and their economic advantages. Most advantageous thicknesses for die casting are 0.75-2.5 mm. for the Sn-Pb alloys; 1.5-2.5 mm. for Zn alloys; 2-3.5 mm. for Al alloys. Corners and angles should be avoided. They should be rounded off by a radius of at least 0.5-1 mm. Suggestions for the best arrangements of the metal molds are given. Ha (12b)

Pouring Practice for Avoidance of Defects in Aluminum Ingots for Rolling. G. L. Craig (Battelle Memorial Institute). *Metals & Alloys,* Vol. 2, Oct. 1931, pages 192-196.

2 references. The author describes several defects in aluminum sheet and states that the more difficult to control, slivers, are due to non-metallics or spongy metal in the ingot. The author describes a method of slow casting in a slowly rotating chill mold. The metal is poured with ladle very close to the mold which is at a slight angle from the horizontal and, as the mold fills, the mold is slowly turned until it finally assumes a vertical position where the slow pouring is continued to feed the pipe. This method of pouring eliminates segregation of inclusions and limits the spongy portion to the very top of the ingot. WLC (12b)

Die Casting of Brass. (La coulée sous pression du laiton.) Lebruly. *Revue Fonderie Moderne,* Vol. 25, Sept. 10, 1931, pages 331-333.

Description of molds, mode of operation and a machine. Ha (12b)

112-Ton Ingot Mould. *Engineering,* Vol. 131, Mar. 6, 1931, page 339.

An illustration is given of mold made by the Brightside Foundry & Engineering Company, Ltd. Ingots larger than any ever before produced in England can be made in this mold. Ingots will be used to produce heavy rotors, hollow forgings for high-pressure chemical vessels, etc. It is being used at the Vickers works of the English Steel Corporation, Ltd. LFM (12b)

Alloy Steel Guns Cast Centrifugally with Mounts of Welded Parts. *Iron Age,* Vol. 125, May 22, 1930, pages 1521-1522.

The process of centrifugally casting guns permits a more rapid manufacture and a superior product. The material is a Mo steel of 0.35-0.4% C and about 0.4% Mo. After casting, the one-piece muzzle is subjected to a cold-working process by hydraulic pressure up to 120,000 lbs./in.^{2} by which the elastic limit of the steel is increased. The mount is made entirely of welded parts. For melting the material, a high-frequency electric furnace was used. The largest gun made in this way weighed about 8000 lbs. Ha (12b)

Liquid Metal is Pressure-Cast into Steel Dies. *Foundry,* Vol. 59, Jan. 1, 1931, pages 75-78.

After some historical remarks on die-casting, methods for die-casting in machines are described and some installations and their operation are illustrated. Ha (12b)

Steel Casting Pattern Allowances for Contraction or Shrinkage and for Machine Finish. *Research Group News,* Vol. 8, Oct. 1931, pages 424-428.

General discussion of the manner in which these allowances should be determined. Ha (12b)

Best Pouring Temperature for Babbitt. Correspondence from James Brinn, Chicago, Ill. *Metals & Alloys,* Vol. 2, Oct. 1931, page 180.

The casting temperatures for babbitt bearings are discussed in the light of the effect of grain size on the wearing characteristics. WLC (12b)

Casting Pipe Centrifugally. S. B. Clark. *American Machinist,* Vol. 75, July 30, 1931, pages 201-203.

The de Lavaud process is described. By it, pipe is cast centrifugally. Molten iron is introduced into a cylindrical metal mold inclined slightly to the horizontal, completely enveloped by hot water and rotating at a comparatively high velocity. Iron is fed into the mold through a trough with a curved spout at its lower end. The stream of iron discharging from the spout flows tangentially to the surface of the mold where it is held in place by centrifugal force thus forming a homogeneous pipe; the pipe is later annealed at 1700° F. 10 pipes of 6-10 in. in diameter and 10 ft. long could be produced hourly in a machine which is described in detail. The microstructure of such pipe is much more uniform and finer grained than sand cast pipe and has a tensile strength of 30-35,000 lbs./in.^{2}, a modulus of rupture of 50-60,000, a modulus of elasticity of 10-13,000,000 and a Shore hardness of 30. Larger machines are now being built. Ha (12b)

Superheating of Crystal Nuclei (Das Problem der Ueberhitzbarkeit von Kristallkeimen). R. Bloch, T. Brings & W. Kuhn (Technische Hochschule Karlsruhe). *Zeitschrift für physikalische Chemie,* Sect. B, Vol. 12, June 1931, pages 415-426.

The melting process is considered as a surface phenomenon. Although thermo-dynamically less stable, small crystals exist for a longer time in a melt than larger ones. Large, slightly damaged crystals dissolve rapidly at the broken boundary surfaces, but the smaller ones require a heat of activation to dissolve off the undamaged surfaces resulting in a slower rate of melting. Fluctuations in the life time of crystal nuclei are calculated. The fluctuations amount to about 10% of the life time at the beginning of the crystallisation process and for nuclei of ordinary size. Rolling (12c)

Advantages of Twin-Motor Drive for Rolling Mills. R. H. Wright & H. E. Stokes (Westinghouse Elec. & Mfg. Co.) *Iron Age,* Vol. 128, July 2, 1931, pages 12-14, 20.

From a paper read before the Association of Iron & Steel Electrical Engineers in Cleveland. The principle advantages of twin-motor drive for reversing service are: (1) motor capacity applied to a single pair of rolls is greatly increased; (2) pinion losses, repairs and maintenance are eliminated; (3) motors may be designed to have greatly reduced inertia; (4) roll chatter and spindle vibrations are eliminated; (5) higher rolling speeds are maintained and tonnage is increased. VSP (12c)

New Designs of Rolling Mill Bearings. H. Weinlig. *Blast Furnace & Steel Plant,* Vol. 19, Mar. 1931, pages 402-405; Apr. 1931, pages 551-552.

The latest German practice of using all-wood bearings with forced lubrication is described and examples are illustrated. See *Metals & Alloys,* May 1931, page 106. Ha (12c)

Machining (12g)

The Elements of Metal Cutting. Orlan W. Boston. *Engineering Research Bulletin* No. 5, *Department of Engineering Research University of Michigan,* Ann Arbor, Dec. 1926, pages 1-95.

This paper gives an account of an investigation in the fundamental elements of metal cutting. The object was to determine a relation between the force on the tool in the direction of the cut for a constant cutting speed of 20 ft./min. and the degrees of sharpness, the various tool angles, width and depth of cut and the physical properties of the materials cut. The latter consisted of 3 C steels, 3 alloy steels, brass and annealed and unannealed cast iron. The cutting was confined to straight-line motion on a planer. The tools used were of the end-cutting type. No cutting fluids were used and but one element was varied at a time. The results show that the clearance angle has no influence on the force. Thick chips are removed more efficiently than thin chips and narrow chips more efficiently than wide chips. All tests and their results are given in detail and a number of appendices for recording tests and a bibliography supplement the paper. Ha. (12g)

Expansion Fits with Liquid Air. E. V. David & W. S. Farr. *Power,* Vol. 74, Oct. 6, 1931, pages 506-507.

The pin, shaft, bushing, etc., are machined to a diameter slightly larger than the hole to be fitted, cooled in liquid air, placed in hole and heated to room temperature. AHE (12g)

The Progression of Commercial Accuracy—Turning, Grinding, Lapping. *Grits & Grinds,* Vol. 22, Feb. 1931, pages 1-10.

A brief historical sketch of the development of the 3 processes, of which lapping is the most delicate, to obtain the highest degree of accuracy. Fields for its use, hand lapping and machine lapping are discussed and a list of machine parts with their successful application is added. Ha. (12g)

Drawing and Stamping (12h)

Stretcher Strains Depend Upon Speed of Draw. Joseph Winlock & A. E. Lavergne (Edw. G. Budd Mfg. Co.) *Metal Progress,* Vol. 20, Sept. 1931, pages 90-93.

Authors present a study of the effect of speed of working on the appearance of stretcher strains, "worms" or lines of Luder in deep drawn articles. Previous treatment as to speed of drawing or heat treatment are shown to influence the appearance or non-appearance of such strain markings. The study of the effect of previous treatment suggests methods of avoiding these strains. WLC (12h)

Forming Properties of Thin Brass Sheets. W. A. Straw, M. D. Helfrick & C. R. Fischrupp. *Metal Stampings,* Vol. 4, Mar. 1931, pages 247-248; *American Machinist,* Vol. 74, Apr. 9, 1931, page 593.

Abstract of a paper presented at the New York Meeting of the American Institute of Mining and Metallurgical Engineers, week of Feb. 16, 1931. See *Metals & Alloys,* Vol. 2, July 1931, page 136. RHP & JN (12h)

Lubrication and Application of Tungsten-Carbide Dies. C. R. Longwell. *Wire & Wire Products,* Vol. 6, Oct. 1931, pages 391-392, 411.

The author notes the extreme pressures a lubricant has to stand in wire drawing. It should be applied directly before the die to give best results. The question of lubricants for wire drawing has not yet been solved satisfactorily. The possibility of hot drawing to almost the right size and then making the last passes cold is discussed briefly. Ha. (12h)

Construction and Uses of Typical Dies, Part IV. Edward Heller. *Metal Stampings,* Vol. 4, Apr. 1931, pages 341-342, 350.

Discusses construction features and applications of an adjustable type of die which severs blanks from a strip instead of cutting around the blanks, a general utility die for notching square corners and a piercing die for a wide range of shapes and sizes of holes. MS (12h)

Factors Affecting Wire Drawing and Methods of Doing It. R. R. Tatnall. *Iron Age,* Vol. 127, Feb. 19, 1931, pages 629-631.

The mechanics of wire drawing is briefly explained. Wire is drawn for 3 purposes: to shape the metal into a convenient form, to obtain a desired size and to give increased strength to it. Some of the limitations of this process and the means of overcoming are discussed. Only a certain reduction can be made at a single draft; after a certain number of successive drafts, an intermediate annealing is required. As long as the metal is not abused, the structure is improved to a considerable degree by drawing. Ha. (12h)

Carboloy Dies. *Carboloy,* Vol. 3, Nov. 1930, pages 14-15.

Tungsten carbide is particularly fitted for dies for drawing bars, tubes and wires on account of its almost diamond-like hardness. In one mill, for example, where a 0.191 die was employed, the average wear after 300 t. of wire was 0.001 for each 99 t. of wire drawn. The question of lubricant is not yet sufficiently solved. Ha. (12h)

Experiments in Wire Drawing: Part I. Behaviour of the Composite Rod. Alkins & Cartwright. *Engineer,* Vol. 152, Oct. 2, 1931, pages 358-359.

Abstract of paper read before the Institute of Metals, Zurich, Switzerland, Sept. 15, 1931. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 272. LFM (12h)

Refinements in Die Practice. C. V. Dorer. *American Machinist,* Vol. 75, Aug. 6, 1931, pages 233-235.

Discussion of the economical considerations which determine the number and arrangement of dies in quantity and job production. Ha. (12h)

Pressed Metal Work in Making Radio Parts. W. T. Fulton (Surface Combustion Co.). *Iron Age,* Vol. 127, May 7, 1931, pages 1519-1521, 1554.

Describes the metal forming and heat treating appliances at the Stromberg Carlson Telephone Mfg. Co.'s plant at Rochester, N. Y. The metal forming section is equipped with automatic screw machines for various parts. The heat treating furnaces are fired by gas. Low pressure system is used for air regulation. See also "Stamping Equipment Employed in Radio Manufacturing," *Metals & Alloys,* Vol. 2, Nov. 1931, page 272. VSP (12h)

Failures of Railway Materials, Dealing Chiefly with Ferrous Metals. E. A. Wraight & P. Hinde. Government of India Central Publication Branch, Calcutta, 1930. Paper, 6¼x9¾, 61 pages. Price 5s 3d.

Deals with examination of a few failed materials. The preface remarks, "It is surprising, in spite of the knowledge on the subject, how sharp corners persist in manufactured parts, and it seems necessary still to stress the necessity for avoidance of these." Rails, axles, tires, and miscellaneous materials are dealt with briefly. Many of the failures were due to incorrect design or lack of proper care in service, but some axles were supplied without the heat-treatment required by specification and failed due to faulty material.

Failures in wrought iron draw bar hooks were traced to low grade iron in some cases and in others to forging so that the slag lines ran at right angles to the direction of the applied load. The hooks are now being made of 0.35% C steel and failures are rare. Only a few cases of rail failure were examined. These were chiefly due to laps and to secondary pipe in big-end down ingots. H. W. Gillett (13)-B-

Steel Contamination from Stopper Heads. Rich. H. Stone. *Blast Furnace & Steel Plant,* Vol. 19, Feb. 1931, page 278.

As the author estimates that 90% of silicate contamination of ingots are due to stopper heads made of refractories, he advocates the use of a graphite head on the stopper. Ha. (13)

Hair-Line Cracks. T. M. Service. *Iron & Coal Trades Review,* Vol. 122, Feb. 27, 1931, pages 358-359.

The author reviews past literature on the origin of this defect and comes to the conclusion, on the basis of his own experiments, that the defects known as hair-line cracks are due to stress produced as the result of differential cooling. See *Metals & Alloys,* Vol. 2, July 1931, page 136. Ha. (13)

Oxides in Alloy Steels. *Metallurgist,* Jan. 1931, pages 14-15.

In an earlier paper Wasmuht and Oberhoffer (*Archiv für Eisenhüttenwesen,* Vol. 2, 1928-29, pages 829-842) investigated the use of Cl gas as a medium for the decomposition and separation of the metallic portion from the oxygen carriers for carbon, silicon, and manganese steels. In a recent paper Wasmuht (*Archiv für Eisenhüttenwesen,* Sept. 1930, pages 155-159) has extended this investigation to alloy steels. The method depends on the complete decomposition of the alloy and the carbides which are present by Cl gas at temperatures at which the oxides are not attacked. The pure alloying metal, its alloys with iron and the carbides were individually tested as to the possibility of decomposition by chlorine at increasing temperatures. Similarly, the resistance of the oxides to attack by Cl was examined. The experiments were also repeated with the addition of C. Pure Cr metal was first attacked at 400° C. and completely decomposed at 700° C. When alloyed with Fe, the attack commenced at lower temperatures in proportion to the decrease in the percentage of Cr and with an alloy containing 15% Cr complete decomposition occurred at 500° C. The decomposition of chromium carbide begins at 300° C. and is complete at 500° C. Chromium oxide is attacked at about 500° C. to some extent and above 500° C. the attack is stronger in the presence of C. The estimation of chromium oxide in chrome steel by decomposition in Cl gas at 500° C. is, therefore, promising. The decomposition of metallic W commences at 300° C. but the rate is slow up to 500° C. and then increases rapidly to above 700° C. Fe-W alloys are attacked just above 100° C. and the rate of attack increases rapidly up to 300° C. Between 300° and 500° C. the attack is somewhat retarded, possibly owing to the presence of carbide, but decomposition is complete about 700° C. Tungsten carbide is resistant to attack; decomposition commences above 300° C. but at 800° C. is still very incomplete. The oxide is slowly attacked above 500° C. but afterwards more rapidly. In the presence of C it is strongly attacked at about 400° C. Tungsten oxide cannot, therefore, be determined by the Cl method. Metallic Mo is approximately, and ferro-molybdenum completely, attacked at 300° C. The decomposition of the carbide commences at 300° C. but is still incomplete at 400° C. The oxide is slowly attacked at about 300° C. but quite strongly between 500° and 600° C. In the presence of C, the attack sets in earlier and is more complete. It is therefore clear that owing to the relative stability of the carbide, the method is not available for the estimation of oxide, especially as the carbide and oxide cannot be simply and accurately separated in the residue. Ni is attacked by Cl at about 300° C. but as the chloride only begins to volatilize at 500° C. washing out with water is necessary. Nickel steels are attacked at 300° and decomposition is complete at 500° C. and as nickel carbide is not usually present in steel it need not be considered. However, as nickel oxide is very unstable in Cl gas, being strongly attacked at 200° C. and completely decomposed at 700° C. the method was not further investigated. The behavior of Co is very similar to that of Ni. The method of determining chromium oxide in chrome steels was worked out as follows. The decomposition temperature employed was 500° C. and the chromium chloride formed was dissolved in warm water containing stannous chloride. Filtering and washing was carried out on a membrane filter. The silica was estimated by evaporation with hydrofluoric acid, the residue was fused with bisulphate and the Cr in the solution of the melt was estimated by the ferrous sulphate method. The amount of oxide was obtained by calculation from the percentage of Cr. VVK (13)

Mottled Tin Plates. *Iron & Coal Trades Review,* Vol. 123, Oct. 16, 1931, pages 578-579.

The question of whether Bessemer steel or open hearth steel is preferable for tin plate and if the rolling has some effect is discussed. With regard to the flux used, the time of contact or immersion in the tin seems to be of importance, also. This phase of the tinning process has not been thoroughly investigated so far. Ha. (13)

Use of Heat-Resisting Steel in the Determination of Nitrogen by the Jaeger Method. W. Zwieg. *Gas- und Wasserfach,* Vol. 74, June 13, 1931, page 576; reviewed in *Gas Journal,* Vol. 195, July 8, 1931, page 85.

Combustion tubes made from Krupp's NCT_3 steel (supplied by Mannesmann Tube Company) offer many advantages over silica tubes which suffer from a tendency towards devitrification and are ruined if caustic potash solution is allowed to enter them. The metal tubes, which are cheaper in replacement costs over a period, have a higher thermal conductivity than have the silica tubes and are thus brought up to temperature more quickly. The copper oxide may be regenerated in the normal manner, and the ends of the tubes may readily be kept cool by use of wet wicks. MAB (14)

The Detection of Cobalt as Cesium Cobaltinitrites. Note by Herman Yagoda & H. M. Partridge. *Journal American Chemical Society,* Vol. 52, Dec. 1930, pages 4857-4858.

Procedure is as follows: The mixture of cobalt and nickel sulphides from the usual procedure is dissolved in aqua regia and evaporated just to dryness. Residue is dissolved in 1 or 2 cc. of 6 M acetic acid. To this solution 2 cc. of 6 M sodium nitrite and 0.5 cc. of 0.5 M cesium nitrate (or 0.25 M cesium sulfate suggested as a reagent for aluminum) are added and the yellow $Cs_2NaCo\ (NO_2)_6$ precipitates. The Application of the Potentiometric Volumetric Analysis in the Steel Mill Laboratory. Part II. A General Method for the Determination of Vanadium (Die Anwendung der Potentiometrischen Massanalyse im Eisenhüttenlaboratorium. II. Eine allgemein anwendbare Schnellbestimmung des Vanadins). G. Thanheiser & P. Dickens. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung,* Vol. 13, No. 15, 1931, pages 187-191; *Archiv für Eisenhüttenwesen,* Vol. 5, Aug. 1931, pages 105-110.

Report 85. The cold reduction of permanganate by tartaric acid and the manner in which this titration is effected by $MnSO_4$ is described and a rapid method for determining V has been developed. The new method gives reliable results and is always applicable. GN (14)

Determination of Chromium and Vanadium in Ores and Alloys after Oxidation with Perchloric Acid. Hobert H. Willard & R. C. Gibson. *Industrial & Engineering Chemistry,* Analytical Edition, Vol. 3, Jan. 15, 1931, pages 88-93.

Presented before the Division of Physical and Inorganic Chemistry at the Minneapolis meeting of the American Chemical Society September 1929. 17 references. Cr and V may be completely oxidized to chromic and vanadic acids by boiling with 70% perchloric acid, the oxidizing action of which is removed by dilution with water, after which any of the usual titration methods may be used. Mn is not oxidized. Directions are given for applying the process to the analysis of chromic oxide, chromite, steel, and ferrochromium. MEH (14)

Gravimetric and Direct Volumetric Determination of Cadmium. R. C. Wiley. *Industrial & Engineering Chemistry,* Analytical Edition, Vol. 3, Jan. 15, 1931, pages 14-15.

Cd may be determined by precipitating as cadmium molybdate and weighing as such. It may be determined also volumetrically by titrating with a standard ammonium molybdate solution, using a saturated solution of pyrogallol in chloroform as indicator. MEH (14)

The Iodide Method for Copper. Bartholow Park. *Industrial & Engineering Chemistry,* Analytical Edition, Vol. 3, Jan. 15, 1931, pages 77-82.

25 references. A short and accurate method for determining Cu in ores, slags, mattes, etc., has been developed and the effect of pH value and of the presence of other metals has been investigated. MEH (14)

Foundation and Methods of Chemical Analysis by the Emission Spectrum. Translation of "Die Chemische Emissionsspektralanalyse" by Walther Gerlock and Eugene Schweitzer. Adam Hilger, Ltd., London, 1931. Cloth, 6¼x10 inches, 123 pages.

This attractively printed booklet presents the author's reasons for expecting spectrographic analysis to come into wider use and, in considerable detail, the methods used in this laboratory as well as other current technique. They prefer spark-spectra to arc and claim the 4 following advantages for spectrographic analysis over ordinary chemical analysis: "expedition, the possibility of analysis of minute quantities of material, the entire preservation of the available material, and the facility of ascertaining the distribution of an element in a given substance."

The subject matter is divided into 7 chapters including theoretical aspects, discussion of equipment, qualitative and quantitative analysis, refinements by photometric measurements and special problems. The book is entirely free from any advertising for the publishers and is well worth while for the prospective user of spectrographic equipment as well as those directing analytical work. C. P. Larrabee (14)-B-

Separation and Gravimetric Determination of Osmium. *Journal Franklin Institute,* Vol. 211, Mar. 1931, pages 374-375.

Brief description of very accurate method for determining Os. At a pH of 4.0, Os is completely precipitated as hydrated osmium dioxide, which coagulates well and settles quickly. Filtered on a Gooch or Monroe crucible, washed with hot 1% NH_4Cl, moistened with a strong solution of NH_4Cl, heated and reduced in a H atmosphere, cooled in H and finally CO_2, and then weighed as metal. DTR (14)

Investigations on Helium. X. on a Method for the Determination of Minute Quantities of Radium (Heliumuntersuchungen. X. Über eine Methode zur Messung kleinster Radiummengen). F. Paneth & W. Koeck (University of Königsberg). *Zeitschrift für physikalische Chemie, Bodenstein Festband,* 1931, pages 145-151.

A method has been developed for the determination of radium emanation down to 10^{-13} Curie with an accuracy of 20%. The utilization for geological age determinations is set forth. See *Metals & Alloys,* Vol. 2, Oct. 1931, page 230. EF (14)

HISTORICAL & BIOGRAPHICAL (15)

Development of the Modern Blast Furnace. Geo. E. Rose. *Blast Furnace & Steel Plant,* Vol. 19, Feb. 1931, pages 255-257.
An historical sketch of the successive changes of lines and dimensions from 1880 to the present-day furnaces of large capacity. Ha. (15)

The Ancient Egyptians had Hardened Steel. Henry D. Hibbard. *American Machinist,* Vol. 74, Apr. 16, 1931, pages 602-605.
The ancients had Au, Ag, Hg and bronze but none of these would have been hard enough to do the work which was done. If stone tools had been used, some of the worn tools should remain. Wrought iron free of C has a higher melting point than the ancients could obtain; by adding C, they could melt it and make steel. Some of the statuary contains marks of cutting that indicate very hard tools. Worn steel tools are not found because they were remelted for other uses. RHP (15)

The Ancient Egyptians had Stone, not Steel. E. J. Tangerman. *American Machinist,* Vol. 74, Apr. 23, 1931, pages 654-657.
A rebuttal of the articles entitled "The Ancient Egyptians had Hardened Steel" by Henry D. Hibbard. Claims that the Egyptians did their work with stone and abrasives—not steel. RHP (15)

Prehistoric Iron Plants in the Siegerland (Vorgeschichtliche Eisenschmelzen im Siegerland). O. Krasa, *Stahl und Eisen,* Vol. 51, Oct. 15, 1931, pages 1287-1289.
The results of recent excavations in the oldest iron ore mining district of Germany give some insight into construction and method of operation of those old hearth furnaces for processing iron. Some analyses on slags and lumps are given. Documents prove that the first blast furnaces with water driven blowers were known in that district around 1300. GN (15)

Evolution of Malleable in France (L'evolution de la malléable en France). R. Gailly. *Congress International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 871-873.
A general and brief survey. Cites unsuccessful efforts to improve malleable by addition of Ni. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 316. HWG (15)

85-Year-Old Cast Iron Pipe Still in Use in Boston. *Water Works Engineering,* Vol. 84, Oct. 7, 1931, page 1430.
Length exposed of line installed in Boston Common in 1846. Pipe was manufactured in Scotland. CBJ (15)

Famous Men of Carron. *Foundry Trade Journal,* Vol. 45, Aug. 13, 1931, page 104.
A brief reference to the work of Major-General Henry Shrapnel, the inventor of the shell which bears his name. The first shrapnel shells were manufactured at the Carron works, and some interesting references to the early accounts in this connection are made in this brief article. OWE (15)

Ten Years of Research for the Metal Industries. A Review of the work of the B. N. F. M. R. A. *Metal Industry,* London, Vol. 39, July 19, 1931, pages 37-38.
Mention is made of all the work of the British Non-Ferrous Metals Research Association. PRK (15)

Ancient Greek Iron. William Campbell (Columbia University) & Ernest E. Thum. *Metal Progress,* Vol. 20, Nov. 1931, pages 43-49.
The authors report a metallographic examination of ancient specimens of Athenian iron made about 425 B.C. WLC (15)

The Tin Industry; the Development of Tin-Mining. *Tin,* July 1931, pages 5-9.
A brief story of history and present status and methods of tin mining in England. Ha. (15)

Rolling Steel Today is a Science. W. H. Melaney. *Blast Furnace & Steel Plant,* Vol. 19, Jan. 1931, pages 105-107.
Impressions of a thoroughly experienced engineer with regard to the practice of former days and those of today. Ha. (15)

ECONOMIC (16)

Zinc Metallurgy in 1930. J. A. Singmaster. *Mining & Metallurgy,* Vol. 12, Jan. 1931, pages 30-31.
This review finds that flexible smelting processes capable of producing special products or recovering valuable by-products are more important than small cost reductions in standard processes. Ha (16)

The Basic Bessemer Process: Some Considerations of its Possibilities in England. V. Harbord. *Engineer,* Vol. 151, May 22, 1931, pages 565-566.
Abstract of paper read before the Iron & Steel Institute May 1931. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 275. LFM (16)

Production Economy in Iron and Steel Works. Part II.—Costs of Production. O. Cromberg. *Iron & Steel Institute, Advance Copy* No. 6, Sept. 1931, 26 pages.
A discussion of cost accounting in metallurgical works. The advantages of time studies and piece work rates are stressed. Examples for determining costs in typical operations are given. JLG (16)

Canadian Plants Combat Steel Mill Problems. *Iron & Steel of Canada,* Vol. 14, Aug. 1931, pages 130-132.
A description of the difficulties under which Canadian plants have to function and of the products which Canadian steel mills undertake to make, which serve to indicate the complexity of the steel business as conducted in the Dominion. OWE (16)

Present Position and Development of the Japanese Steel Industry. H. Yoshikawa. *Proceedings World Engineering Congress,* Tokyo, 1929, Vol. 33, published 1931, *Mining & Metallurgy,* Part 1, pages 163-211.
In Japanese. A one-page English list of subjects dealt with is given but the actual information in the paper is not summarized. HWG (16)

A Glance at the Italian Metallurgical Industry (Prospettive dell' Industria Siderugica Italiana). L. Norsa. *Metallurgia Italiana,* Vol. 23, Oct. 1931, pages 897-908.
General and statistical. 12% of the steel production of Italy is from the electric furnace. HWG (16)

Economic Planning in the Mineral Industry. Thos. T. Read. *Mining & Metallurgy,* Vol. 12, Sept. 1931, pages 406-409.
Discussion of some of the social and business problems as well as the technical problems involved. Ha (16)

Changing Sources of Metals. W. A. Scheuch. *Mining & Metallurgy,* Vol. 12, July 1931, pages 322-323.
The author notes that secondary sources of metals have become so important as to justify well designed and carefully located units capable of producing high quality products. Some statistics prove this, particularly for Cu and Pb the quantities of which, available from secondary sources in the U. S., amount to more annually than the primary Cu produced by Arizona and the primary Pb produced by Missouri. Ha (16)

Point System for Determining Molding Rate and Costs. W. J. McNeill (Federal Malleable Co.). *Iron Age,* Vol. 128, Sept. 3, 1931, pages 614-615.
Abstract of a paper read before the American Foundrymen's Association. The system consists of assigning values to each part of the mold making operations, values being expressed in points. The sum of the points represents the total value of the various operations, but does not express it as the price of the mold. To convert the total points into the price/100 molds, the total must be multiplied by the hourly earning coefficient. To the resulting figure is added the pouring, which is paid for at the rate of 10c/cwt. of casting weight/100 molds. This system has been used by the Federal Malleable Co. since 1922. VSP (16)

Is Silver a Commodity? Tsuyee Pei. *Mining & Metallurgy,* Vol. 12, Feb. 1931, pages 86-88.
The use and value of silver as a monetary basis and its national-economical importance in international relations is discussed. It is not considered a commodity in countries that are on a silver basis, but as the standard value of currency. Ha (16)

Variations in Yield Exert Great Influence on Brass Foundry Costs. J. B. Meier. *Foundry,* Vol. 59, Feb. 15, 1931, pages 43-46.
Tables are compiled showing the change of profits with varying numbers of workers, varying output/man, varying yield and because of defective castings. Ha (16)

Steel Consumption in the United States and Germany. A. Michels. *Iron Age,* Vol. 128, July 16, 1931, page 176-179, 208.
The per capita consumption of steel for the 2 countries is compared. Only in the item of bars has the German per capita consumption approached that of the United States closely and surpassed it in 2 yrs. The American consumption of tinplate is about 6 times that of Germany. The distribution of steel orders to private enterprises and the government show, for the latter, a very large percentage in Germany. For details, the paper must be consulted. Ha (16)

Accounting with Sliding Cost Factors in Foundries. (Das Rechnen mit gleitenden Unkostensätzen in Giessereibetrieben.) H. Jordan. *Archiv für Eisenhüttenwesen,* Vol. 5, Oct. 1931, pages 219-222.
Report 52 of the Committee on Plant Efficiency of the Verein deutscher Eisenhüttenleute. The author makes some suggestions as to better accounting in foundries, and deals with the advantages which his proposals offer in comparison with the methods used at present by German foundries. GN(16)

Scrap Conserving the Nation's Iron Ore Resources; Large Tonnages Added Yearly to Record of Lake Reserves. A. J. Hain. *Steel,* Vol. 88, Jan. 1, 1931, pages 262-265.
The life of the higher grade iron ore deposits in the Lake Superior district is estimated at 20 to 25 yrs. This figure disregards the ever increasing use of scrap by steelmakers. Better methods of reclaiming scrap and wider use of it in iron and steel manufacture will greatly extend the above estimate. During 1920-1929, scrap iron consumption increased 61%, while iron ore consumption increased only 9.9%. There was an average annual decline of 40 lbs. of ore consumed/ton of iron and steel produced. Some open-hearth producers report as high as 55% of scrap in their annual output. In 1929, the iron and steel industry used over 30 million tons of scrap, representing over 43% of its total output. This resulted in conserving over 20,750,000 tons of ore. The tax records of Minnesota and Michigan show reserves of ore sufficient for more than 27 yrs. JN (16)

PLANTS & LABORATORIES (17)

Electrical Equipment for Steel Mills. H. A. Winne. *Blast Furnace & Steel Plant,* Vol. 19, Jan. 1931, pages 109-110.
Description of some new large motor installations with auxiliary equipment made in 1930. Ha (18)

Melt Aluminum in Electrically Heated Pot Furnaces. W. S. Scott. *Foundry,* Vol. 59 Oct. 1, 1931, pages 67-68.
Describes an installation of 2 furnaces of 200 lbs. of molten Al/hr., each. The operating costs total $.586/100 lbs. Ha (17)

India's Only Copper Producer—The Indian Copper Corporation. Russell B. Woakes, *Engineering & Mining Journal,* July 27, 1931, pages 51-53.
A description. Flowsheets are shown for the concentrator, the smelter and the pulverized coal plant. WHB (17)

Plate Mill of the Gulf States Steel Co. W. Worthington. *Blast Furnace & Steel Plant,* Vol. 18, Nov. 1930, pages 1709-1710.
Brief discussion of a 32 in. universal plate mill with auxiliary equipment. Ha (17)

Heat Treating Parts in Automobile Fan Manufacture. H. M. Heyn (Surface Combustion Co.). *Iron Age,* Vol. 128, Sept. 3, 1931, pages 616-619.
Describes the plant of the Automotive Fan & Bearing Co., Jackson, Mich. The principle kind of fan made is a plain bearing with lubricating pump in the fan hub. In the heat treating room, 40 x 40 ft., there are 2 furnaces, one of which is used for carburizing. It is of the counter flow type. Gas is used for heating. It uses 447 ft.^{3} of 530 B.t.u. gas/hr., heating 285 lbs. of work to 1650° F. The other furnace is of the V-notch pusher type used for hardening; it heats 200 lbs. of work/hr. to 1500° F., using 252 ft.^{3} of 530 B.t.u. gas. VSP (17)

MACHINERY & SUPPLIES (18)

Steel-Mill Tonnage Increased by Twin-Motor Roll Drives. H. H. WRIGHT & H. E. STOKES (Westinghouse Elec. & Mfg. Co.). *Electric World,* Vol. 98, July 25, 1931, pages 164-166.

The recently developed twin-drive for reversing mills, in which each of the mill rolls is driven by an individual motor has five conspicuous advantages over the common single-motor drive: (1) the motor capacity applicable to a single roll is greatly increased, (2) pinion losses, repairs and maintenance are eliminated, (3) the motors may be designed to have greatly reduced inertia, resulting in less strain on the equipment, more torque available for useful work, reduced motor and generator heating and faster acceleration, (4) roll chatter and spindle vibration are practically eliminated, (5) higher rolling speeds can be maintained and mill tonnage can be increased. WHB (18)

Devices for Conveying Steel Sheets. FRANK M. FISH. *Blast Furnace & Steel Plant,* Vol. 18, Aug., 1930, pages 1329-1333.

Deals with transportation of sheets from the mill to the railroad cars by means of conveyors, power trucks and hand operated trucks. MS (18)

Crane Equipment in Foundries. *Foundry Trade Journal,* Vol. 45, Sept. 3, 1931, page 152.

After classifying electric handling apparatus into 2 broad classes, intermittent and continuous, the author deals with various types of crane in some detail and then turns his attention to the electrical equipment with which cranes are ordinarily supplied. The various factors which must be considered when installing electrically operated travelling cranes are dealt with. OWE (18)

A New Centrifugal-Casting Machine. *Foundry Trade Journal,* Vol. 45, July 23, 1931, page 51.

A description of a machine for the manufacture of gear wheels, rings, etc., which has been successfully used in the production of ferrous and non-ferrous castings up to 3 ft. in diameter or more. The machine, which is produced by Messrs. Craven Brothers (Manchester), Limited, of Reddish, Stockport, England, is shown in sectional elevation; a photograph of the machine also accompanies the article. OWE (18)

The Revolver Core-Making Machine. *Foundry Trade Journal,* Vol. 45, July 16, 1931, page 45.

A description of a core-making machine utilizing the principle of forcing the sand into a core box by means of compressed air operating at 60-85 lb./in.^{2} The paper is accompanied by 4 photographs and 2 diagrams, showing the plan and the elevation of the machine, respectively. OWE (18)

Machine for Rolling Heavy Metal Forms. *Iron Age,* Vol. 126, July 31, 1930, page 299.

Describes machines for forming heavy sheet metal into window framing, cornice molding and door butts. VSP (18)

Molding Cores by Compressed Air. *Engineering Progress,* Vol. 12, May, 1931, pages 110-111.

Detailed description of a foundry core revolver, a core-making machine produced by the Albertus Werke, Hanover, Germany. Ha. (18)

A Large Rolling-Mill Drive. *Electrical Review,* Vol. 108, Mar. 13, 1931, page 464.

Description of the equipment and control of 12,000 hp. DC motor for a 27 in., 3-stand reversing mill for 30/70 r.p.m. maximum speed 110 r.p.m. It is supplied by a motor-generator fly wheel set running at 600 r.p.m.; the weight of the fly wheel is 21 tons, weight of the mill motor, 114 tons. Ha. (18)

Modern Electric Welders. *Electrical Review,* Vol. 108, Mar. 20, 1931, pages 506-507.

Brief description of characteristic performances of welding-transformers and welding dynamos of British manufacture. Ha. (18)

Quick Work Shear for Cutting Circles in Steel Plate. *Boiler Maker,* Vol. 31, Sept., 1931, pages 249-250.

A large shear for cutting plates up to 72 ins. in diameter is described. The shearing speed is about 40 lineal ft./min. An average of 750 pieces can be cut in 11 hrs. The operation costs $3.45/hr., of which $2.70 is for labor and $0.75, for roughing out the plates. Ha. (18)

Compressed Air for Forge Hammers. *Heat Treating & Forging,* Vol. 16, Aug., 1930, pages 985-988.

Notes the advantages of air over steam for operating forging hammers and describes a few installations. Ha. (18)

MISCELLANEOUS (20)

Copper-Oxide Rectifiers. KARTAR SINGH. *Electrical Review,* Vol. 109, Aug. 14, 1931, pages 247-248.

An element of ordinary copper oxide rectifier is formed by heating a disk of Cu about 1/16 in. thick in air or O to about 1040° C. whereby cupric and cupric oxides are formed; the latter is in a liquid state and reacts with the O in the air and the cupric oxide is dissolved in the cuprous oxide. The dissolved cupric oxide appears in the form of crystals embedded in crystals of cuprous oxide and separated from metallic Cu by a layer of practically pure cuprous oxide which makes this layer an imperfect dielectric and allows a leakage path to the electrons. This results in a slow discharge of the asymmetrical condenser metallic copper-cuprous oxide-cupric oxide. The theory of the density of electron flow is developed, the double-wave rectification is described and the action of the copper-oxide rectifier is explained; also explained by the ionic theory. Ha. (20)

The Influence of Curvature on the Strain Distribution in Cylindrical Helical Springs (Der Einfluss der Krümmung auf die Spannungsverteilung bei zylindrischen Schwaubenfedern). ROTHHAAS. *Zeitschrift Verein deutscher Ingenieure,* Vol. 75, October 17, 1931, pages 1315-1316.

A theoretical discussion and development of formulas for the determination of inner stresses in helical springs of very small diameter where the usual formulas no longer give correct results. 4 references. Ha. (20)

British Cast Iron Research Association. *Foundry Trade Journal,* Vol. 45, July 9, 1931, page 18; July 16, 1931, page 34; July 23, 1931, page 50; July 30, 1931, page 66; Aug. 6, 1931, page 80; Aug. 13, 1931, page 96; Aug. 20, 1931, pages 112, 124; Aug. 27, 1931, pages 128, 132; Sept. 3, 1931, page 142.

A brief outline of progress made by the B.C.I.R.A. since 1921. The first article is accompanied by a graph, showing the relationship between subscriptions and total income during the period 1921-1931. The manner in which the Government grant to the Association is handled is discussed and methods of levying subscriptions are also considered. The second article deals with the conditions of membership. The types of members described are (1) ordinary members, (2) trade and user members, (3) associate members. The terms of membership and the method by which the Association is governed are dealt with in some detail. The third article gives a description of the laboratories and the office accommodations. The fourth article contains a brief statement of the services rendered to the members. These services may be grouped as follows: (1) information from the library and information bureau; (2) confidential research reports on investigations in progress; (3) assistance in the application of discoveries made by the Association to particular industrial requirements and the solution of problems incidental to the production of castings. The fifth in the series deals with experimental work in progress. The program includes investigations on molding sands and refractories, heat-resisting cast iron, ingot-mold irons, malleable cast iron, cupola melting practice, light castings, alloy additions to cast iron, strength of cast iron in relation to design, and the structure and mechanical properties of gray iron in relation to melting conditions. In the sixth article, a brief statement is given of the advantages of the work of the B.C.I.R.A. to the foundry industry in Great Britain. The seventh article includes a brief statement of the government of the association. In the 2 concluding installments, the government is described in detail. Reference is made to the various technical sub-committees and the work covered by each. OWE (20)

Pocket Companion, Abridged Edition. Illinois Steel Company, Chicago, 1931. Paper, 6 x 9 inches, 318 pages.

The revised series of CB sections presented in this book is a joint compilation of the Carnegie Steel Company and the Illinois Steel Company. In addition to data pertaining to the CB series, information is also given covering the more commonly rolled sections used in structural design, as well as in car and ship building. Although the book is abridged in character, it contains all data ordinarily required by the user of structural shapes. M. L. Moorman (20)-B-

Marking Steel with Acid. *American Machinist,* Vol. 75, Aug. 27, 1931, page 343.

The fluid consists of nitric acid (38° Baumé) 75 parts, nitrate of silver 2 parts, water 23 parts. It can be used with pen or rubber stamp. Ha. (20)

The Light Metals at the 12th Milan Fair (I metalli leggeri alla XIIa fiera di Milano). *Metalli Leggeri,* Vol. 1, May-June, 1931, pages 12-24.

Description and photographs of exhibits. HWG (20)

Questions on Steam Turbine Operation (Fragen des Dampfkesselbetrieb). *Archiv für Wärmewirtschaft und Dampfkesselwesen,* Vol. 12, June 1931, pages 185-186.

Reviews meetings of and papers presented before Mitgliederversammlung der Vereinigung der Grosskesselbesitzer, Apr. 22, 1931, at Dresden. Papers were given by: Professor Bauer on "Boiler Injuries," Marguerre on "Operating Experiences with High-Pressure Systems," Lugberger on "Research Program for Alloyed Tubing." MAB (20)

The Dependence of Damping upon the Deformation Velocity (Die Abhängigkeit der Dämpfung von der Verformungsgeschwindigkeit). O. FÖPPL. *Archiv für Eisenhüttenwesen,* Vol. 4, June 1931, pages 607-608; *Stahl und Eisen,* Vol. 51, June 25, 1931, page 796.

In order to determine the dependence of damping on the deformation velocity, 3 different cases must be distinguished: (1) alternating loads below the yield point; (2) alternating loads with materials, the oscillating strength of which is above the yield point; (3) predominating flow of material with deformation. In the first case, the capacity of damping is independent of the deformation velocity; in the second case, the capacity of damping decreases with the velocity; and in the third case, the capacity of damping increases with the velocity of deformation. GN (20)

A New Research Tool. R. F. PASSANO. *Pure Iron Era,* Vol. 9, No. 39, page 23.

The principle of the statistical theory is explained and the importance of its application to research problems for evaluating test data is illustrated by means of an example. Ha. (20)

Fluid-Film Lubrication as Applied to Journal Bearings. F. O. WILLHOFFT. *Railway Mechanical Engineer,* Vol. 105, Aug. 1931, pages 410-411.

From the exhaustive paper the following summary is given: (1) The supply of oil must be sufficient at any speed to maintain an unbroken film of the necessary thickness over the whole load-carrying surface; it must also be sufficient to make up for oil lost by leakage at the 2 ends of the bearing. In order to preclude the breaking down of the film at any point, the supply must be greatly in excess of the requirements; according to tests, this amounts to about twice the oil loss through end leakage. (2) Oil should always be available at the loading edge of the bearing and over the whole length of it in sufficient quantity to permit formation and maintenance of a solid oil wedge; the edges of the bearings should, for this purpose, be rounded or chamfered. (3) The inside of the bearing in the pressure zones should not have any grooves or holes communicating with atmospheric or low pressure zones in order not to interfere with the building up of the pressure in a continuous oil flow. (4) The bearing arc should be long enough to permit the required maximum pressure; 90°-100° (sometimes even 60°) are sufficient. (5) The peripheral speed of the journal must be sufficient to permit the formation of the complete film of adequate thickness; the minimum speed at which greasy lubrication changes to fluid lubrication is still a question. Ha. (20)

FOUNDRY PRACTICE & APPLIANCES (22)

Molding Sand Condition is Related to Pin Holes and Low Ductility. GEO. BATTY. *Foundry*, Vol. 59, Oct. 15, 1931, pages 30-33.

The use of a proper molding medium has eliminated the sources of pin hole troubles by solving the problem of properly carrying off the gases from the mold. Green sand is suitable for the elimination of this trouble. It is explained why the addition of Al to shank ladles results in the formation of alumina. The various methods of addition are discussed. Ha. (22)

Some Fundamental Questions of Testing Molding Sands and their Utilization in the Foundry (Ueber einige grundsätzliche Fragen der Formsandprüfung und ihre Nutzbarmachung im Giessereibetrieb). AULICH. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Oct. 9, 1931, pages 793-800.

The characteristics of a molding sand are discussed and a tentative classification of sands according to contents of alumina and grain size is given. The mechanical-physical testing as the basis for maintaining uniformity of quality and the importance of water in the sand is discussed. Ha. (22)

Tests for the Use of Pig Iron Produced under Slag of High Alumina Contents as Addition for Gray Iron Castings (Ueber Versuche zur Verwendung von unter hochtonerdehaltiger Schlacke erzeugtem Roheisen als Zusatzeisen für Grauguss). M. PASCHKE & E. JUNG. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Oct. 2, 1931, pages 777-786.

In the Luebeck Blast Furnace Plant, a special pig iron is produced in the manufacture of an alumina fusion cement which has a composition of 4.5-5.3% C, 0.1-0.5% Si, about 0.5% Mn, 0.08-0.15% P, 0.01-0.03% S and up to 0.02% Al. The slag consists of about 45% $Al_2O_3+TiO_2$, 42% CaO and less than 10% SiO_2. This special iron, called H-K special pig iron, was tried as an addition to gray castings and steel. Segregation was very greatly reduced hereby and a good mobility was obtained in spite of very low P content. This promises well for castings of thin walls. The strength was good. This iron seems to give good results for hard castings and malleable castings also. Ha. (22)

Pattern Lumber Includes a Variety of Woods. NORMAN F. HINDLE. *Foundry*, Vol. 59, Sept. 1, 1931, pages 51-53; Sept. 15, 1931, pages 36-37.

Part I deals with the grading rules, defects and methods of drying pattern lumber. Part II. Mahogany, cherry, maple, beach and birch are hardwoods used more for the manufacture of patterns than other woods. Defects include knots, splits, wane, worm grub, rafting pin holes, etc. The question of seasoning is the basis of controversy among patternmakers. Case hardening is the most common defect in seasoned lumber. VSP (22)

Makes Largest Steel Casting. *Foundry*, Vol. 59, Sept. 1, 1931, pages 46-50.

Describes casting produced at Lehigh plant of the Bethlehem Steel Co. The weight of casting was 460,000 lbs. Gross weight of metal in casting, including sink heads, runners and gates was 580,000 lbs. The analysis of the steel used was: C, 0.20-0.25%; Mn, 0.45-0.50%; S, 0.04%; P, 0.025%; Si, 0.22-0.25%. VSP (22)

Proper Sand Control and the Low Ductility Problem. GEORGE BATTY (Steel Castings Development Bureau). *Iron Age*, Vol. 128, Sept. 24, 1931, pages 810-811, 819.

From a paper read before the American Foundrymen's Association. Low ductility in light steel castings is the product of higher physical properties with proper sand control. Pin-hole troubles and low ductility are identified with green sand practice. Mold gases and not gases coming from steel are the cause of pin-holes. The addition of Al is the major cause of low ductility. The opinions of other metallurgists are given. VSP (22)

The Graphic Calculation of Cupola Mixtures, with Special Reference to "Perlit" Cast Iron. *Foundry Trade Journal*, Vol. 44, May 21, 1931, pages 351-352.

An extended abstract of an article which appeared in *Die Giesserei*, wherein B. Szöke describes a graphic method with the aid of which the proportion of the different components of a mixture can be easily determined when the molten Fe is to contain a definite percentage of one of its constituents, e.g., Si. The method can be applied when 2 or 3 different kinds of pig Fe are used, together with returned scrap, gates, and risers, provided the latter contain the same percentage of Si as the molten Fe. The article is accompanied by 5 diagrams. OWE (22)

Casting of Beds of Large Machine Tools in Metal Molds (Giessen grosser Werkzeugmaschinenbetten auf Kokille). A. WINDHAUSEN. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Mar. 6, 1931, pages 204-206.

The procedure of molding pieces taking into consideration the deflection due to unequal wall-thickness, and the preparation of the metal molds is described in detail. Ha (22)

A Comparison of Natural-Bonded and Synthetic Moulding Sands for the Steel Foundry. H. J. COLE. *Foundry Trade Journal*, Vol. 45, Sept. 10, 1931, pages 159-161.

Extended abstract of paper presented before the A. F. A. See *Metals & Alloys*, Vol. 2, Aug. 1931, page 150. OWE (22)

Complexities of the Steel Foundry. *Canadian Foundryman*, Vol. 22, June 1931, pages 12-13; July 1931, pages 10-11; Aug. 1931, pages 16-17.

Report of an address presented before the Steel Founders Society of America by Frederick A. Melmoth, who divides the complexities into 3 main groups—metallurgical, mechanical, and administrative. Methods of attacking the metallurgical problems of the foundry are outlined and improvements are dealt with which may be expected as a result of careful control of the factors involved. The mechanical problems are defined as those that become operative on the metal after it leaves the control of the molding department; these are dealt with in some detail and special reference is made to mold design and theories underlying it. The latter part of the paper deals with the question of casting, selling, and the choice of executives. See also *Metals & Alloys*, Vol. 2, Jan. 1931, page 15. OWE (22)

Sand-Spun Pipe. W. A. Brown (R. D. Wood & Co.) *Journal American Water Works Association,* Vol. 23, Apr. 1931, pages 551-560.

The manufacture and physical properties of "sand-spun" centrifugally-cast cast iron. VVK (22)

Correct Design of Castings. (Sachgemässes Konstruieren von Gusstücken.) *Giesserei-Zeitung und Giesserei,* Vol. 18, Jan. 16, 1931, pages 64-67.

The proper design of a pulley to obtain a casting free of internal stresses is shown. Ha (22)

Steel Foundry Practices Based on Study of Variables. F. B. Pletcher. *Foundry,* Vol. 59, June 15, 1931, pages 34-38.

The methods of handling, storing and testing of material for the operation of the foundry of the Burnside Steel Foundry Co., Chicago, are described in detail and some of the products are illustrated. Ha (22)

Melting Difficulties with Small Quantities of Special Iron. Ecossais. *Foundry Trade Journal,* Vol. 43, July 10, 1930, page 32.

Castings for engineering work must be close grained and reasonably free from blow and shrink holes. Typical analysis of the metal used is: total C, 3.2%; Ni, 1.2-1.5% depending on thickness; Mn, about 0.75%; P, about 0.35%; S, about 0.1%. This is poured at about 1350°-1400° C. In addition to using special irons, foundrymen often apply chills to equalize the rate of solidification of the thicker sections in order to overcome segregation and consequent open grain. VSP (22)

Progress Marks Malleable Casting Industry. E. E. Griest (Chicago Railway Equipment Co.). *Foundry,* Vol. 59, Sept. 15, 1931, pages 44-46.

Abstract of a paper read before the Quad-City Foundrymen's Association. Discusses gradual improvement in physical properties of malleable iron, the adoption of modern melting and other equipment and the development in the annealing process. VSP (22)

Carbon Can be Regulated by Cupola Practice. G. Olson. *Foundry,* Vol. 59, Apr. 1, 1931, pages 62-63.

The author believes that the C content of cast iron can be regulated very well in the cupola melting process by additions of steel scrap and gives a table showing the amount of scrap to be added for different amounts of C in charge and casting. Ha (22)

Clay and Sand Properties Play Important Part in Synthetic Sand Mixtures. N. J. Dunbeck. *Foundry,* Vol. 59, Oct. 15, 1931, pages 42-43.

The quality of sand and clay in the manufacture of synthetic molding sands has a great influence on durability, refractoriness, strength, moisture retentiveness. These points are discussed and simple tests for these properties are described. Ha (22)

What Will Prevent Blows and Pin Holes? Geo. Batty. *Foundry,* Vol. 59, Feb. 1, 1931, pages 69-70.

The moisture content of the sand near the face of the mold and the interparticle atmosphere of the sand is liable to promote defects in the casting. The ability of a molding sand to produce castings free from blows and pinholes has no strict relation to its permeability. Highly permeable facing is most dangerous when it is backed by a close, relatively impermeable backing sand. A good principle to observe in the manufacture of green-sand castings is to be sure that the permeability of the backing sand is not less than that of the facing sand. Ha (22)

Competitive Pressure Spurs Foundry Improvements. *Steel,* Vol. 88, Jan. 1, 1931, pages 286-287, 361.

Improvements in foundry products and processes have resulted from the economic depression. Institutions and private firms have fostered technical research and standardization. The foundry has made wider use of mechanical firing equipment and other labor-saving devices. Progress has been made in casting steel alloys of Ni, Cr, Mn, Mo and V; research has been carried out on casting alloys of Si, Cu, and Zn to replace Sn and on alloys of Mg and Be for aircraft manufacture. Advances have been made also in the short-time annealing of malleable iron in electric furnaces, in the heat treatment of gray iron and in the technic of die casting of Zn, Al and Cu base alloys. JN (22)

Match Plate Checking Methods Involve Extreme Accuracy. H. N. Tuttle. *Foundry,* Vol. 59, Feb. 15, 1931, pages 62-65.

Methods of accurate checking are illustrated. Ha (22)

Simplified Molding with Template (Vereinfachte Lehrenformerei). Freytag. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Oct. 23, 1931, pages 825-826.

The manner in which template molding can be carried out by workmen who are unable to read drawings is shown. Ha (22)

Molding Large Non-Ferrous Castings Requires Wide Experience. Edwin Bremer. *Foundry,* Vol. 59, Apr. 1, pages 48-51, 59.

General remarks on the importance of pouring temperatures, molds, number and arrangement of risers, cast-in baffle plates, etc.; examples are shown. Ha (22)

Pressure and Volume of Air in the Cupola (Etude de la pression et du volume d'air dans les cubilots). J. Canameras y Gonzalo. *Congres International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 783-784.

2 cupola runs with a good coke and with a spongy, fragile coke showed the importance of coke quality. Even with higher pressure of air, 43 vs 40 gr./cm.^{2}, enough could be supplied, the furnace taking only 60 m.^{3}/min. against 63 with the better coke, and the iron was cold. HWG (22)

A Few Novelties in the Castings of Automobile Pistons (Quelques nouveautes pour la coulee des pistons d'Automobiles). *Revue Fonderie Moderne,* Vol. 25, Oct. 25, 1931, pages 379-380.

See *Metals & Alloys* (Fischer, *Giesserei,* Apr. 10, 1931), Vol. 2, Dec. 1931, page 319. Ha (22)

Annealing and Melting Furnaces for Aluminum, Especially Fuel-Fired Furnaces (Note sur les fours a recuire et les fours de fusion pour l'aluminium et ses alliages, en particulier fours chauffés). A. de Zeerleder. *Congres International des Mines de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 611-620. 17 figures.
Sketches of the construction and brief description of the performance of a wide variety of furnace types. HWG (23)

Dimensions and Capacities of the Checkers of Upper-Silesian Open Hearth Furnaces (Ueber Abmessungen und Leistungen der Wärmespeicher oberschlesischer Siemens-Martin-Ofen). F. Wesemann. *Stahl und Eisen,* Vol. 51, July 9, 1931, pages 873-883; July 16, 1931, pages 908-911.
Report 210 of the Steel Mill Committee of the Verein deutscher Eisenhüttenleute. The paper summarizes the results of a questionaire sent to the Upper-Silesian open hearth plants. GN (23)

The Physics of the Combustion of Solid Fuels (Zur Physik der Verbrennung fester Brennstoffe). P. Rosin & H. G. Kayser. *Zeitschrift Verein deutscher Ingenieure,* Vol. 75, June 27, 1931, pages 849-857.
Assuming that the combustion of coal on the grate should follow the same laws of flow as the dissolving of solid bodies in flowing liquids, the authors attacked the problem of the physics of combustion by observing the reaction between the surface of a solid body and a liquid because the same conditions hold good in combustion. A brick of finely ground salt pressed at 2000 atmospheres was chosen as a model and was exposed to the flow of water at different velocities. The reactions of a single body and of a bed of bodies as on a grate, the aero-dynamics of the grate and of combustion of powdered fuel are investigated and explained and relations are found for dimensions and arrangement of grates, directing of air, excess of air and incidental features of combustion. 15 references. Economics of Electric Heating. N. R. Stansel (General Electric Co.). *Heat Treating & Forging,* Vol. 16, July 1930, pages 908-910.
From paper read before World Power Conference. Discusses economics of heating and use of electricity in the heat treatment of steel. Capacity of electric furnaces installed in the United States for heat treating steel amounts to about 300,000 kw. Use of electricity insures a high and uniform quality in the material treated. MS (23)

Physicing Bottoms of Dormant Open Hearth Furnaces. C. W. Veach. *Iron Age,* Vol. 127, Feb. 12, 1931, pages 546-547.
Some practical information on the means of putting an open hearth into condition again after it has been dormant for some time during which it has been cold and subject to natural deterioration. Ha (23)

The Changing Status of the Gas Produced in the Iron and Steel Industry. Geo. V. Slottman. Paper presented at *Third International Conference on Bituminous Coal,* Nov. 16-21, 1931 (Pittsburgh, Pa.).
The regeneration principle of Siemens, introduced in the steel industry since 1868, has led to an extensive consumption of gaseous fuel. While this was formerly covered by the gas producer, the by-product coke oven has, since 1914, begun to take its place and will ultimately eliminate the gas producer, altogether. For high temperature melting and reheating operations, coke oven-blast furnace gas mixtures are now being extensively used. The proper preparation of the raw gases from the blast furnace allows a more efficient utilization in the blast-furnace auxiliaries. In a properly balanced steel plant, the waste heat available from coke ovens and blast furnaces is more than sufficient to meet the total heat requirements; the use of solid and liquid fuels is confined to peak loads and to meeting irregularities in the supply of waste gases. Tables for coke production, relative proportion of solid, liquid and gaseous fuels used in American open-hearth furnaces, heat and power requirements/ton of ingot, and daily waste heat production and consumption are added. Ha (23)

The Action of an Eddy Current Melting Furnace for Low Frequency Three-Phase Current (Ueber Wirkungsweise eines Wirbelstrom-Schmelzofens für niederfrequenten Drehstrom) U. Schwedler. *Archiv für Elektrotechnik,* Vol. 25, Oct. 12, 1931, pages 669-682.
The theory of a furnace of this kind is developed and a testing arrangement for checking the calculations is described. Ha (23)

Rapid Open-Hearth Furnaces. N. E. Skaredoff. *Iron & Coal Trades Review,* Vol. 122, Jan. 16, 1931, page 81.
Furnaces designated by this name are able to give 5-6 charges daily irrespective of the capacity. Furnaces of this type mean a great economy in investment as well as in operation compared with the usual type of equal capacity or a small number of furnaces of a very great capacity. The author describes a construction in use at the Kamakshi Steel Works in Japan giving one charge of 25 tons every 4-5 hrs. The charge consists of 20-30% of molten pig from the blast furnace direct; 20-30% of cold pig and 35-50% of steel scrap. The fuel is coke-oven gas and coal tar, the consumption about 50 kg. of tar and 200 m.^{3} of gas which corresponds to 1,200,000 cal./ton of ingots (or 4,760,000 B.t.u./ton.) Ha (23)

Open Hearth Furnace Control. M. J. Conway. *Fuels & Furnaces,* Vol. 9, Aug. 1931, pages 919-920, 953; *Iron Age,* Vol. 128, July 23, 1931, pages 244-245, 278.
See *Metals & Alloys,* Vol. 2, Sept. 1931, page 189. Ha (23)

Possibilities of the Electric Furnace (Les possibilités du four electrique). P. Marthourey. *Congrés International des Mines, de la Métallurgie et de la Géologie appliquée. Section de Métallurgie,* 6th session, Liege, June, 1930, pages 227-245. 57 illustrations.
A general survey of progress of electric steel, with some attention to cast and malleable iron. A plea is made for the use of electric steel for rails. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 321. HWG (23)

On the Ultra Red Radiation of Refractories (Ueber die Ultrarotstrahlung feuerfester Körper). B. Wrede. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung,* Vol. 13, No. 19, 1931, Report 179, pages 131-142; *Stahl und Eisen,* Vol. 51, Aug. 6, 1931, page 1007.
The ultra red radiation of various refractory bricks was investigated with a spectrometer and compared with the radiation of the black body. The investigation method is described and the results are tabulated and plotted in diagrams. In the table below, the capacity of absorption is the relation between the radiation of the brick considered and the radiation of a black body of the same temperature.

Radiator	Composition	Temperature ° C.	Capacity of absorption	Remarks
Silica brick	95% SiO_2,	1217	66	———
Chamotte	55% SiO_2, 41% Al_2O_3	1229	59	Surface rough
Sillimanite brick	33% SiO_2, 64% Al_2O_3	1402	29	———
Corundum brick	70% Al_2O_3, 30% clay	1344	46	Surface rough
Magnesite brick	80% MgO	1377	39	———

Special Refractories for Use at High Temperature. Wm. H. Swanger & F. R. Caldwell. *Brick & Clay Record,* Vol. 79, Aug. 25, 1931, pages 170-172.
The oxides of Th, Mg, Zr and Be can be used as refractories in which to melt metals of highest purity without injurious contamination of the metal by the refractory. See *Metals & Alloys,* Vol. 2, Sept. 1931, page 190. Ha (24)

The Development of Some Special Refractories. H. E. White *Fuels & Furnaces,* Vol. 9, Sept. 1931, pages 1061-1066; Oct. 1931, pages 1155-1162.
In the beginning, the author points out that a faulty furnace design can never be overcome even by the best refractory. Silicon carbide, refractory cements, crystalline Al, mullite, high purity Mg, Zr (which possesses high mechanical strength under temperature) thermal insulation are discussed. Their properties and fields of application are described. Ha (24)

Refractory Materials for the Induction Furnace. J. H. Chesters & W. J. Rees. *Iron & Coal Trades Review,* Vol. 123, July 17, 1931, pages 78-79; July 24, 1931, pages 122-123; July 31, 1931, page 156.
The induction furnace offers particularly difficult problems in the production of durable linings which, beside refractoriness and chemical durability, must possess resistivity to severe strains imposed on it by the rapid rate of heating and the steep temperature gradient between the molten metal and the water cooled coil. See *Metals & Alloys,* Vol. 2, Sept. 1931, page 190. Ha (24)

The Thermal Expansion of Some Refractory Oxides. James Bliss Austin. *Journal of the American Ceramic Society,* Vol. 14, Nov. 1931, pages 795-810.

Material	Total expansion between 20° and 1000° C. in parts/10,000 ∥ principal axis		Total expansion between 20° and 1000° C. in parts/10,000 ⊥ Principal axis	Thermal conductivity of brick at 500° C.x10[4]
Quartz (SiO_2)	87		169	
Magnesia (MgO)		135*		103
Alpha alumina (Al_2O_3)	89		82	82
Zirconia (ZrO_2)	56		89	42
Chromite ($FeO \cdot Cr_2O_3$)		80*		39
Zircon ($ZrO_2 \cdot SiO_2$)	60		33	—
Mullite ($3Al_2O_3 \cdot 2SiO_2$)	55		44	—

*Relation to principal axis not given.

The Pulfrich-Fizeau interference method as modified by the Bureau of Standards was employed in making the measurements. There appears to be no conclusive evidence at hand as to the relative expansion of a single crystal and an aggregate. In most cases the expansion of the aggregate is lower than that of the single crystal. Commercial brick would therefore have an expansion somewhat lower than its chief constituent in the pure crystalline state. WAT (24)

Refractories for Use in Tunnel Kilns. M. C. Booze. *Fuels & Furnaces,* Vol. 9, Feb. 1931, pages 205-212.
Description of the various kinds of refractories and their requirements as determined by service conditions up to 2000° F., as well as some installations. Ha (24)

Refractories Industry Awake to Value of Research. *Steel,* Vol. 88, Jan. 1, 1931, pages 292, 359.
The refractories industry is being elevated from rule-of-thumb methods to a new era of engineering precision by virtue of the research work being prosecuted in manufacturing plant laboratories and in government, society and institutional laboratories. The past year has witnessed a more general use of continuous kiln burning methods, the production of special shapes and materials, the development of a crystalline, aluminum-bodied brick, the wider adoption of zirconium oxide refractories, improvements in furnace linings, the production of electrically fused magnesia for furnace linings, the development of high temperature cements and new patching materials for furnaces, a more extensive use of chromite ore refractories, and a more general adoption of the power press process of brick manufacture. JN (24)

Foundry Refractories. Jas. R. Allen. *Fuels & Furnaces,* Vol. 9, June 1931, pages 669-670.
A review of the standardization of fire bricks and some of the standards already adopted. Ha (24)

Lining for Electric Furnaces. *Brass World,* Vol. 27, July 1931, page 156.
A new lining material, Furnaseal C-8 (Super Ram), for electric furnaces is marketed by Laclede-Cristy Clay Products Co., St. Louis, Mo. It is claimed to be useful in patching linings of furnaces for metal melting. Monolithic linings are produced and patches made with it become homogeneous with the lining. It has high slag resisting properties. Maintenance is reduced to a minimum, the material burns very hard and withstands abrasion well. It is recommended for furnaces melting Ni and Cu alloys. WHB (24)

GASES IN METALS (25)

Solubility of Oxygen in Solid Iron. N. A. Ziegler (Westinghouse Electric & Mfg. Co.). *American Society for Steel Treating, Preprint* No. 1, 1931, 10 pages.

Paper presented at the Boston Convention of the Society, Sept. 1931. Bibliography of 34 references. The author briefly discusses previous work and the vacuum method of analysis for O. The author's procedure of saturating samples of low C iron with O at various temperatures is described. From analyses of these samples, a curve of O content against temperature is shown. Up to 700° C. (1292°F.) the O content is negligible increasing slowly to 900° C. (1652°F.) and rapidly thereafter to reach a maximum of 0.10% in the neighborhood of 1000° C. (1832° F.). The effect of C on the solubility of O is quite marked as shown by a curve. WLC (25)

The Hardness of Electrolytic Nickel and Iron (La dureté du nickel et du fer électrolytique). Guichard, Clausman, Billon & Lanthony. *Congres International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 525-526.

Evolution of H_2 and of $CO+CO_2$ on heating was studied in relation to the change of hardness. Practically all the H_2 is released from Ni before the hardness drops materially. Softening is practically complete before evolution of $CO + CO_2$ is appreciable. In the period where the hardness drops from about 240 to about 45 Brinell, the H has been released, and the $CO+CO_2$ have not yet been evolved. The gas contained in electrolytic Ni cannot be the cause of its hardness. A similar situation was found in Fe, the hardness remaining at about 365 after most of the H has been released. Evolution of $CO+CO_2$ occurs at lower temperatures than with Ni, but it is not thought by the authors to be a cause of softening. The hardness of the electrolytic deposits of both Ni and Fe is ascribed to small grain size. HWG (25)

Oxidation—a Cause of Porosity in Leaded Bronze. E. Doughty (Federal Mogul Corp.). *Metals & Alloys,* Vol. 2, Oct. 1931, pages 181-183.

The author reports results obtained with a bearing bronze 80% Cu, 10% Sn and 10% Pb by melting under a reducing atmosphere, by deoxidizing oxidized metal with cupro-phosphorus and with zinc. Self-fluxing from oxides lighter than the metal is possible but heavy oxide of Pb does not rise out of the bath and results in porosity unless some powerful deoxidizer is used. WLC (25)

Nitrogen in Mild Steel. *Metallurgist,* Dec. 1930, pages 186-188.

An extended critical review of a paper by Köster ("The Problem of Nitrogen in Commercial Steel," *Archiv für Eisenhüttenwesen,* Apr. 1930 page 637). The causes of some of the changes in the properties of commercial steel which occur during mechanical and thermal treatment at temperatures below A_1 are still obscure. Mechanical "aging" —the term applied to the loss of toughness of cold-worked steel—and magnetic "aging," which consists in a deterioration of the magnetic quality in the course of time, are phenomena which still need a clear explanation. As a result of his work, Köster suggests that as these changes occur in the α iron phase, they cannot be of an allotropic nature, but must be constitutional and that. therefore, the solubility of certain substances in α iron must be dependent on the temperature. The usual impurities in iron, such as oxides, sulphides, etc., are probably soluble only to a very small extent, and the problem of investigating their effects requires the use of methods which are sufficiently sensitive. The solubility of nitrogen in α iron, as deduced from a number of experiments, is as follows: at room temperature, 0.001% N; at 200° C., 0.005% N; 300° C., 0.01% N; 400° C., 0.02% N. The presence of carbon in the super-saturated solution retards the precipitation of nitride at the lower temperatures. The effect is more pronounced with larger percentages of carbon and the separation of nitride may even be entirely suppressed. The separation of nitride is accompanied by a small increase in the specific gravity, the tensile strength and hardness are diminished, the angle of twist and the reduction of area are increased and the yield point and elongation are not markedly affected. The change in the mechanical properties is proportional to the percentage of nitrogen. Alloy steels are capable of retaining larger quantities of nitrogen in solution. VVK (25)

The Fixation of Gases (Hydrogen, Nitrogen) to Highly-Disperse Metals (Iron, Nickel) Deposited from the Vapor Phase (Ueber die Bindung von Gasen (Wasserstoff, Stickstoff) an hochdispersen, aus der Dampfphase abscheidenen Metallen (Eisen, Nickel). W. Frankenburger, K. Mayrhofer & E. Schwamberger. *Zeitschrift für Elektrochemie,* Vol. 37, Aug-Sept. 1931, pages 473-482.

If Fe is slowly evaporated and condensed on a cooled surface, the fine particles are able to bind very large amounts of H. The purpose of the investigation was to note if Ni, Pt, Mo, W and Ta behaved in a similar way and if, beside H, Ni, A and mixtures of Ne and He were also absorbed. The amount of the absorbed gas per metal atom was determined, also, as a function of the ratio quantity of NaCl/quantity of metal. The tests are described in detail; for the discussion, the results of the paper must be referred to. 15 references. Ha (25)

The Absorption of Nitrogen by Steel. R. S. Dean. *Heat Treating & Forging,* Vol. 17, May 1931, pages 460-464.

Report of U. S. Bureau of Mines No. 3076. The Fe-N diagram is a simple solubility curve increasing with temperature. Without cold working, the iron nitride when precipitated does not go into solution on long periods of heating below 300° C. The presence of nitrides may cause blue brittleness and hardening, even at very small percentages of N. The mechanical properties, in general, may be influenced in unexpected ways. The magnetic qualities show no permanence in the presence of N, either. These questions and the role of other additions and impurities, the use of possible denitrifiers are thoroughly discussed. It is recommended that the steel maker find means of controlling the N content of at least part of his metal. At present, no proven method for doing this exists. 37 references. The Effect of Molybdenum on Medium-Carbon Steels Containing 1 to 2.5 Per Cent of Manganese. G. Burns. *Engineer,* Vol. 152, Oct. 2, 1931, page 347; *Iron & Coal Trades Review,* Vol. 123, Oct. 2, 1931, pages 490-491.

Exhaustive tests were made on the effect of Mo on the mechanical properties susceptibility of steels containing 1.3 and 2.3% Mn to temper brittleness and their tendency to mass effect. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 323. Ha & LFM (27)

Silicon in Steel Making. Henry D. Hibbard. *Fuels & Furnaces,* Vol. 9, Sept. 1931, pages 1037-1051.

A full discussion of the very important functions of Si in steel making and the properties it imparts. Its occurrence in the charge material; the control of boil of the bath; gases in crude iron; dead bath; hot Bessemer blow; in the melting and working period; reversion of Si; additions of Si at different stages; preventing formation of gas holes; killing; lessening segregation in the ingot; silica in acid and basic slag; promoting of fusibility; raising tensility; lessening electric power losses; retarding corrosion; the time required for the different functions are treated in detail. Ha (27)

The Effect of Molybdenum and Titanium Upon Grey Cast Iron. *Foundry Trade Journal,* Vol. 45, July 16, 1931, page 39.

Abstract of an article by J. H. Küster and C. Pfannenschmidt (in *Die Giesserei,* 1931), accompanied by a diagram showing the effect of increasing the Mo content on the graphite content, the resistance to shock, the Brinell hardness number, and the transverse and tensile strengths of cast Fe containing about 3.4% total C and about 2.5% Si. Another diagram shows the effect of introducing Ti into a number of cast irons of varying Si contents. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 282. OWE (27)

Influence of Silicon on Nickel Steel. R. Harrison. *Iron & Coal Trades Review,* Vol. 123, Oct. 2, 1931, page 494.

In a steel of 4% Ni, 0.4% C, 0.3-0.8% Mn and 0.05-0.87% Si, the latter raises the critical points and has a hardening effect, whether in the forged, rolled or normalized condition. See *Metals & Alloys,* Dec. 1931, page 323. Ha (27)

The Effects of Iron on the Electrical Conductivity and Tensile Strength of Aluminum. M. Kuroda. *Supplement, Scientific Papers Institute of Physical and Chemical Research,* Vol. 16, Sept. 5, 1931, pages 1-2.

By the addition of electrolytic Fe to Al at melting, the electrical resistance and tensile strength increase proportionally to the Fe content. For each 1% of Fe in aluminum with 0.3-0.4% Si, the variation is 0.15 microhm for resistance and 1.5 kg./mm.^{2} for strength. For practical use as transmission wires, an Fe addition is preferable for strength as well as for conductivity. 20 references. Ha (27)

Alloy Additions Improve Gray Iron Pressure Castings. F. J. McGrail. *Foundry,* Vol. 59, Jan. 15, 1931, pages 52-55.

The addition of Cr and Ni has a favorable influence on the structure and properties of cast iron. The iron must be heated to 2600° F. to obtain proper results in melting Cr and Ni in the iron. This alloy is good for use in motor cars, steam or hydraulic cylinders. The ratio of Ni to Cr should be about 3-4-1, except in very heavy sections of 1½ ins. or more, when additional amounts of Cr can be added. The use of 2 Ni equals 1 of Si for the same C content. The proper method of mixing is explained and the structures are shown in micrographs. Ha (27)

Alloys at Work. *Inco,* Vol. 10, No. 4, 1931, pages 9-10.

A brief enumeration of the advantages of Ni as an alloy material and some applications. Ha (27)

Zirconium Additions Affect Steel and Gray Iron. *Foundry,* Vol. 59, Oct. 15, 1931, pages 44-46.

Comparative tabulations showing the beneficial influence of small additions of Zr to castings are given. Resistance to impact and hydrostatic pressure are greatly improved; strength and deflection are improved to some extent. A decided refinement of the grain structure was noted; this resulted from the deoxidizing and denitrogenizing effect of Zr. It is added in the form of zirconium-ferrosilicon containing 12-15% Zr, 40-45% Fe and 39-43% Si; as Si-Zr; or as Zr-Mn-Si. Methods of making these additions are described and the amounts to be added are given. Ha (27)

Gun Metal Strength is Affected by Phosphorus. H. C. Dews. *Foundry,* Vol. 59, Mar. 1, 1931, pages 63-65.

The effect of P on the admiralty gun metal, or the 88-10-2 alloy, was investigated. It was found that between 0.04 and 0.07% P, a sharp reduction of tensile strength takes place. Brinell hardness increases up to the addition of 0.04% and then decreases. Density decreases as the P is increased from 0.06 to 0.13%. P promotes the ease of casting and the casting temperatures have an influence on tensile strength and elongation, as is disclosed by curves taken between 1250° C. and 1000° C. Around 1100° C., a maximum exists in various alloys. The tests are described in detail. See also *Metals & Alloys,* Vol. 1, Oct. 1930, page 789. Ha (27)

Seasoning of Steel, Effect of Carbon, Nitrogen and Copper in Small Amounts. E. W. Ehn (SKF Companies, Cannstadt, Germany). *Metal Progress,* Vol. 20, Sept. 1931, pages 59-64.

The author presents equilibrium diagrams showing solubilities in α iron of 0.04% C, 0.50% N, and 3.5% Cu. The solubility increases with temperature and the values given are the maximum solubilities. Quenching from elevated temperatures still within the α range results in substantial supersaturation. Aging or drawing such quenched material results in precipitation hardening of the alloy. Treatments applicable to Fe-C, Fe-N and Fe-Cu alloys are discussed with properties obtainable. Effects of Cr, W and Be are discussed briefly. WLC (27)

INSTRUMENTS & CONTROLLERS (28)

The Use of Pyrometers in the Brass Foundry (Die Verwendung von Pyrometern in der Messinggiesserei). G. Wolfe. *Giesserei mit Giesserei-Zeitung* Vol. 18, Aug. 7, 1931, pages 639-642.

The necessity of supervision of the pouring temperatures for brass is pointed out and the possibilities and types of pyrometers answering this purpose are described. The only satisfactory thermo-couple is that for direct immersion but no type has yet been developed that does not show a great wear. The use of bare wires which are simply pressed together and can be easily renewed after burning off is, therefore, recommended. The optical pyrometers have not given satisfaction on account of the surface of the molten metal. Ha (28)

Temperature Regulators for Metallurgical Furnaces (Ueber Temperaturregler an metallurgischen Öfen). F. Kofler & G. Schefels. *Siemens-Zeitschrift,* Vol. 11, Oct. 1931, pages 448-453.

Describes the electrical connections of a temperature regulator for blast-furnaces, annealing furnaces, and pusher type furnaces. Ha (28)

The Remote Measuring Equipment of the Friedrich Alfred Plant at Rheinhausen (Die Fernmessanlage der Friedrich-Alfred-Hütte zu Rheinhausen). J. Wittig. *Stahl und Eisen,* Vol. 51, Sept. 17, 1931, pages 1161-1164.

The paper gives a detailed, illustrated description of all equipment controlling the energy of the plant mentioned above. The remote measuring equipment is centralized in 3 places and composed of a central measuring station for gas, air and compressed air, a station for controlling the blast furnaces and stoves and one station for the water plant. GN (28)

Automatic Control of Open-Hearth Furnaces. W. Trinks. *Mining & Metallurgy,* Vol. 12, Aug. 1931, pages 360-364.

The automatic control of combustion air, of maintenance of proper pressure in the furnace, of temperature and the means for doing it are discussed. It is noted that automatic control is usually more efficient and more cheaply done than regulation by hand. Ha (28)

Temperature Measurements in the Foundry (Wärmetechnische Messungen in der Metallgiesserei). W. Winkhaus. *Giesserei mit Geisserei-Zeitung,* Vol. 18, Mar. 13, 1931, pages 227-229.

The article deals, in a general way, with the influence on the quality of the product of temperature in drying, melting and pouring, and points out the importance of measuring instruments in the production of sound castings. Supervision of temperatures by recording instruments and of consumption of fuel oil with counters, immersion pyrometers with large scales for melting and automatic recording instruments are briefly discussed and explained. Ha (28)

The Use of Thermo-Couples at High Temperature (Ueber die Verwendung von Thermoelementen in hohen Temperaturen). A. Schulze. *Zeitschrift Verein deutscher Ingenieure,* Vol. 75, June 6, 1931, pages 731-733.

A few recent thermo-couples are described of which the Heraeus couple "32/40" consists of an alloy of gold, palladium and some platinum against a platinum alloy and has, over a range of from 0° to 1200° C. a considerably higher (about 5 times) EMF than the Le Chatelier element of platinum-platinum-rhodium, but its proportionality is poor. Another couple of nickel-nickelsteel can be used up to 1100° C. and one of nickel-carbon up to 1200°; the EMF of both is about half of the constantan-iron couple which, however, is good only up to 900° C. For very high temperature above the melting point of platinum a couple of pure tungsten and 75% W with 25% Mo has been made which is good for 3000° C.; this couple, however, reverses its direction of EMF at about 1200° C. At 500 to 700 volts it has 1.0 mV and at 3000°—6 mV. Ha (28)

Cycle Control for Heat Treating Furnaces. L. B. Crossman. *Fuels & Furnaces,* Vol. 8, Nov. 1930, pages 1551-1552.

A description of the construction and operation of a program control as applied to gas-fired heat treating furnaces. Ha (28)

Contact Pyrometers (Anlege-Pyrometer). W. Claus. *Zeitschrift für Metallkunde,* Vol. 23, Apr. 1931, pages 120-123.

It is important to determine the temperature of cast ingots prior to forging in order that the ingot may be worked at the most favorable temperature. Portable thermo-electric pyrometers for the determination of surface temperatures for this purpose are described, and the principles of their operation discussed. RFM (28)

Photoelectric Tube Pyrometer Controls High Furnace Temperatures. *Steel,* Vol. 89, Nov. 1931, page 36.

In the past it has been difficult to read the high furnace temperatures required in special furnaces used for industrial and laboratory purposes, and it has been difficult to control these furnaces or maintain a set temperature over a period of time. At the annual meeting of the American Chemical Society in Buffalo, in August, Dr. L. R. Koller (General Electric Co.) announced a solution for the problem in using the photoelectric tube to measure the visual energy radiated by the hot body and, thereby, its temperature. The photoelectric tube, with a suitable optical system, looks at the furnace wall, or some object in the furnace. The current in the tube depends on the amount of light falling on it and, accordingly, varies with the brightness of the surface observed. Temperatures as low as 1000° C. can be measured and there is no upper limit. The apparatus is equipped with the necessary amplifier tube, calibrated recorder and mounting stand. WAT (28)

An Air-Thermostat for Corrosion Research. U. R. Evans. *Journal Society Chemical Industry,* Vol. 50, Jan. 23, 1931, pages 66-67.

The principal features of an air-thermostat for corrosion research, details of which are given, are: double walls properly lagged between which, after passing through the main chamber, air is forced by a fan; windows placed where the experiment can be observed without disturbance. Provision is made for heating or cooling the air. A rotating horizontal shaft attached to a slow motion electric motor on the outside is provided for stirring purposes. VVK (28)

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

The abstracts appearing in this section are prepared in coöperation with the Joint High Temperature Committee of A.S.M.E. and A.S.T.M.

Properties of Steel at High Temperatures. R. Willows & F. C. Thompson. *Metallurgia,* Vol. 4, Aug. 1931, pages 109-112.

Experiments were devised to determine whether or not a prolonged stress at elevated temperature affected the properties of steel at room temperature. 2 samples of C steel wire were used, containing 0.39% and 0.15% C respectively. Samples were maintained under a tensile stress at 100°, 200°, 300°, 400° and 500° C. for approximately 5 months. One sample was not loaded, another was loaded ½ of its tensile strength at room temperature and another at ¼. Samples held at 400° and 500° C. could not be loaded at such a high stress. Incidentally some creep values were obtained for the highest temperature. After testing at room temperature no effects of the stresses at elevated temperatures could be detected with the possible exception of the effects obtained at 500° C. Samples held at 300° C., including an unstressed specimen showed slight suggestions of embrittlement. It was concluded that definite embrittlement, which has been observed in practice must be due to some cause such as definite overstressing, vibrational fatigue, or possibly chemical attack. Contains 3 references. JLG (29)

Tempering Stability and Hardness at Elevated Temperature of High Speed Steel (Anlassbeständigkeit und Warmhärte von Schnelldrehstahl). F. Rapatz & H. Kallen. *Stahl und Eisen,* Vol. 51, Oct. 29, 1931, pages 1339-1340.

The authors determined the decrease of hardness with increasing drawing temperature and the hardness at elevated temperatures of various high speed steels containing variable contents of Co, W, Mo and V and a Cr content of 4.00- 4.60%. The results show that high alloy high speed steels have a better tempering stability than low alloy high speed steels. Whereas high alloy steels can be subjected to 600° C. for 15 hrs. without showing a remarkable disintegration of martensite, the low alloy steels show a disintegration even after 1.5 hrs. The hardness of elevated temperature of high alloy steels is also much higher than that of low alloy steels. This is observed even at those temperatures at which martensite is still stable for longer times, i.e., below 550°-600° C. These 2 properties, a greater hardness at elevated temperatures and a better stability during tempering, bring about the better qualities of high alloy high speed steel in comparison with low alloy high speed steel. GN (29)

Metallurgical Creep. *Engineer,* Vol. 151, May 8, 1931, page 506.

A letter by H. A. Humphrey of the Imperial Chemical Industries, Ltd., submitting a formula worked out by A. G. Hinton of the same firm. Proposed formula expresses the relation between stress and log creep strain. Following formula agrees closely with experimental results obtained:

$$C = k\frac{(p-a)^3}{(b-p)^2}$$

C=creep (strain/unit time), p=tensile stress, k, a, b are constants depending upon temperature. The constants have been determined for Ni-Cr, Cr-V, and a stainless steel at 300° C., 400° C., 500° C. and 600° C. and duralumin at 150° C. Figures are given showing points which were worked out experimentally and curves representing the above proposed formula. LFM (29)

Ferrous Materials to Resist High Temperatures. James A. Lee. *Chemical & Metallurgical Engineering,* Vol. 37, Sept. 1930, pages 587-588.

Summary of recent developments. MS (29)

The Red Shortness of Steel by Metals (Der Rotbruch des Stahles durch Metalle). H. Schottky, K. Schichtel & R. Stolle. *Archiv für Eisenhuttenwesen,* Vol. 4, May 1931, pages 541-547; *Stahl und Eisen,* Vol. 51, June 18, 1931, pages 769-770.

The Characteristics of Deformation of Steel under Constant Load at Elevated Temperatures. G. R. Brophy (General Electric Co.). *American Society for Steel Treating, Preprint* No. 4, 1931; *Metal Progress,* Vol. 20, Aug. 1931, pages 54-57.

Paper presented and discussed before the Boston Convention of the Society in Sept. 1931. As result of the study of the deformation of steels under increasing loads and constant loads over a wide range of temperatures, 3 types of steel are recognized, (1) those which show more or less sudden yields above the proportional limit from room temperature up to some elevated temperature, above which the yielding becomes smooth; (2) steels which show smooth load-deformation curves at room temperature and at higher temperature but at intermediate temperatures stepped curves; (3) steels which show smooth curves at all temperatures. The influence of heat treatment on these diagrams and of heat treatment and pre-straining on time deformation curves are discussed. The idea is presented that "creep" is a strain hysteresis which may be mathematically predicted for long periods from tests conducted for shorter times. WLC (29)

The Influence of High Pressure Superheated Steam upon the Structure and Properties of Various Materials for Construction of Engines. Y. Fujii. *Kinzoku no Kenkyu,* Japan, Sept. 1931, pages 498-534.

18 kinds of steels and 3 kinds of Cu alloys, which at present are commonly used in the main parts of steam engines, were exposed in running steam of 35 kg/cm.² at 400° C. as in the actual case and the change of their structure and several properties were studied. Tensile strength, hardness, impact, fatigue and creep tests were also made at such high temperatures as 20°, 200°, 300°, 400° and 500° C. and compared with the results of the running steam tests. From the results, it is concluded that various steels tested are fit for the use in high temperature up to 400° C., though Cu alloys are not available above 200° C. KT (29)

Electric Furnace for High Temperature Tensile Tests (Elektrischer Ofen für Warmzerreissversuche). O. Beckmann. *Metallwirtschaft,* Vol. 10, Sept. 11, 1931, pages 725-726.

Description of construction details of an electric furnace which is attached to a testing machine, in which test pieces were heated for the determination of yield point and long time tensile tests of metals. The temperature is regulated by means of a rheostat between 100° and 1000° C. and determined by a thermocouple and millivoltmeter. A mirror device for measurement of elongation is part of the equipment. In the long time tests, the load was held constant by means of an Amsler constant pressure apparatus. This consists of an adjustable exhaust valve which works in connection with the hydraulic pressure pump. CEM (29)

The Temperature Relations in the Plasticity of Crystals (Ueber die Temperaturabhängigkeit der Kristallplastizität). W. Boas & E. Schmid. *Mitteilungen der deutschen Materialprüfungsanstalten,* Sonderheft 13, 1930, pages 103-109; *Zeitschrift für Physik,* Vol. 61, May 7, 1930, page 767.

A study of single crystals of known orientation of Cd from 20° absolute and of Zn from 85° absolute to the melting points. The influence of the rate of loading on the hardening curve at very low and very high temperatures is small. Curves of the observed data are given. The orientation in a Cd single crystal is not dependent on the work exerted in producing the gliding of the basal plane. This work is a constant (about 9 joules/cm²) at all temperatures. Zn single crystals stretched at 100°-200° C. show transverse markings which may perhaps be due to a tearing of the surface. HWG (29)

Some Considerations Affecting the Future Development of the Steam Cycle. K. Baumann. *Proceedings of the Institution of Mechanical Engineers,* No. 5, 1930, pages 1305-1396.

Includes discussion. Factors affecting and limiting the use of high temperatures and pressures are discussed, among which the creep properties of steels are important. Curves are given comparing the rate of creep in ins./in./hr. for 0.15% C carbon steel and for a Cr-Ni-Mo steel of 0.30% C, 2.50% Ni, 0.60% Cr, 0.60% Mo, 0.60% Mn, oil hardened and tempered to a room temperature strength of 135,000 lbs./in.². These curves show the following relation:

Temperature° F.	Load in lbs./in.² for creep rate shown: 10^{-8} in/in./hr. Carbon	10^{-8} in/in./hr. Ni-Cr-Mo	10^{-5} in/in./hr. Carbon	10^{-5} in/in./hr. Ni-Cr-Mo
750	6,500	22,500	21,000	67,000
800	5,000	15,500	16,500	56,000
900	2,500	5,500	9,500	33,000
1,000	1,500	2,500	4,500	11,000

These are based on creep tests, but, particularly at the lower rates of creep, "they should be regarded only as an intelligent anticipation of the creep properties." Creep curves at 400° C. (750° F.) are shown for 0.40% normalized C. steel loaded at 9,000 lbs./in.² and for Armco iron at 6,700 lbs./in.² The following data are taken from these curves:

	0.40% C	Armco
Initial extension, inches	0.00028	0.00026
Extension at 250 hrs.	0.00038	0.00052
" " 750 hrs.	0.00044	0.00057
" " 1500 hrs.	0.00047	0.00063
" " 2500 hrs.	0.00049	0.00067

Neither curve shows marked diminution of rate in the last 1,000 hrs. of the test. Important differences in rate of creep at 550° C. (1025° F.) are stated to have been found in Ni-Cr-Mo steels of apparently similar composition and heat-treatment and investigation was necessary to determine the thermal treatment for best creep resistance at this temperature. No details of the differences or of the heat-treatments are given.

Comment is made on the fact that the data from older investigations, such as those of Lea, tend to give values for apparently allowable loads that are really unsafe. Later, more refined, tests doubtless give more nearly true values. From the point of view of the designer of steam plants, considerable creep occurs at loads only 25% of those Lea designated as creep limits. Engineering factors concerning the permissible distortion of bolts and piping are considered in detail. In discussion, page 1375, H. E. Geer suggested that a material was needed which would provide ductility equal to that of mild steel at ordinary temperature but which will stand higher stresses up to 1100° F. and avoid the tendency toward brittleness and intercrystalline break-down which occurs with high Cr alloys. It appears that judicious addition of Mo and Cu might have the desired effect. Such a material has recently been brought out by a British steelmaker with which at 400° C. (750° F.) the creep stress is twice, and at 500° C. (930° F.), 3 times that of mild C steel. It is thought that this will make possible higher super heater temperatures, use of thinner tubing and consequent reduction of temperature stresses, beside avoiding danger of internal sealing. Baumann gives permissible creep rates in ins./in./hr. as 10^{-9} for turbine disks pressed on shafts, 10^{-8} for bolted flanges and turbine cylinders, 10^{-7} for steam piping, welded joints and boiler tubes, and 10^{-6} for super heater tubes. HWG (29)

Heat Resisting Steels. *Nickel Bulletin,* Vol. 4, Nov. 1931, pages 321-329.

Heat-resisting Ni-Cr steels, Ni 10-30% and in some cases as high as 60%, and Cr from 7-35%, are now available in all the usual forms. Mechanical properties of a number of types are given for room temperature. The "creep stress" is at present not definite. This is partly due to the fact that it has not been possible to explore all the various compositions, and also to the difference of opinion which still exists as to how the "creep limit" should be defined. Thus, while the results of one investigator are comparable, they are not necessarily interchangeable with those obtained by others. Results obtained by Hadfield, Pilling and Worthington, Henshaw, Bodmer, Aitchison, and others on the physical properties at temperatures from 20°-1000° C., of a number of Ni-Cr heat-resisting steels are given. Some of the numerous uses and applications of heat-resisting steels are enumerated and illustrated. WAT (29)

Limiting Creep Stresses. *Metallurgist,* Dec. 1930, pages 178-179.

The intensified demand of present day engineering practice for metals and alloys that will withstand high temperatures and pressures has placed before the engineer the problem of determining these properties sufficiently accurately that they can be used as bases for design without the introduction of an unnecessarily large safety factor. The difficulty is that, while the investigation of the behavior of materials over a long period of time is necessarily a slow process, the engineer is faced with the problems of the moment and cannot wait for the results of extensive research. The consequence has been a demand for quick approximate methods of determining the "creep stress" of a given steel at various temperatures, and several short cuts of this kind have been devised. It is questionable, however, whether the results of these short methods are sufficiently reliable for them to be used with confidence for design purposes. For relative purposes, the comparison of one steel with another, fairly safe conclusions can be drawn but for purposes of design, where the creep properties must be accurately known, the problem becomes more difficult and complicated. Such factors as the possible effects of gradual rearrangements of internal structure — recrystallization, spheroidizing, etc. — which scarcely come into play in a short time test, may make all the difference in the service life of the material. Cases are known, in fact, in which a material has apparently settled down to a steady and very low rate of creep—possibly even so low as to be practically negligible—and yet, after a certain lapse of time, the rate of flow has increased and rupture has occurred. There would seem to be 2 directions in which a solution of this problem can be reached. The first is an immediate and practical process, leading only to a tentative and temporary result. The engineer must determine, as far as present data will permit, the true creep stress (if such a thing exists), of his materials, increase his factor of safety where forward steps in design are taken and then carefully watch his structures to determine what actually happens. The second method of approaching a solution of the high-temperature problem lies along the road of research, and especially of fundamental research. The question has been raised whether there is a true "limiting creep stress" at high temperatures, or even at the temperature of the air. In regard to the latter point, both laboratory tests and engineering experience go to show that if materials "creep" under prolonged loading at low and moderate temperatures, the rate of creep is negligible for practical purposes and need not be taken into account, so far as steel and the harder metals are concerned, in questions of design. At higher temperatures and in the softer metals the state of affairs may be different and we are in urgent need of further knowledge. It may even be found that the structural condition of a material, determining not only its actual resistance to flow at any given moment during a test, but its stability or resistance to gradual internal changes of a deleterious character, may be of very great importance. VVK (29)

Cold-Treating Dural with Solid CO_2; Cold-Treatment of Alloy Steels. *American Machinist,* Vol. 75, Sept. 17, 1931, pages 439-441, 473.

The rapid age hardening at normal temperatures occurring in alloys of the duralumin type containing both Cu and Mg offers practical difficulties and uncertainties; for instance, when rivets are used which must be heat treated just before being used. The method of overcoming this inconvenience and preventing age hardening before time, by keeping them at about 32° F. immediately after quenching, is explained in detail. The relation between hardening or aging and temperature was investigated closely and diagrams show the changes in tensile strength as function of time elapsed between quenching and testing. In a similar way, alloy steels cold treated with liquid air show marked changes in hardness and physical properties. As an example, the following table for a steel with 17.15% Cr and 5.06% Ni is given:

Quenched from 1090° C. and cold treated at − 80° C. and drawn:

Treatment	Elastic Limit lbs./in.²	Ultimate tensile strength lbs./in.²	Elongation in 2 ins. %	Reduction of area %	Machinability r.p.m.	Brinell No.	B maximum H-300
As quenched	22,500	194,500	17.0	22.6	120	277	3540
C.T − 80° C.	72,500	231,200	8.4	9.6	88	444	9240
Draw 400° C.	100,000	208,000	19.8	64.3	160	444	9970
Draw 500° C.	82,500	187,200	20.6	65.8	221	387	10940
Draw 600° C.	65,000	153,600	19.4	55.9	221	321	8270

Appreciable increases in hardness were also obtained by cold treating a group of alloys containing from 24.73 to 30% Ni at − 180° C. The method of measuring the low temperatures and of testing are described and several tables showing the results are added. Ha (29)

Alloys for Use at High Temperatures. C. H. M. Jenkins & H. J. Tapsell. Parts I, II. *Foundry Trade Journal,* Vol. 45, July 16, 1931, pages 43-44; Part III. *Foundry Trade Journal,* Vol. 45, Aug. 20, 1931, pages 120-122; *Iron & Steel Industry & British Foundryman,* Vol. 4, Aug. 1931, pages 379-380.

Abridgement of a paper presented before the annual meeting of the British Iron & Steel Institute dealing with Ni-Cr and complex Fe-Ni-Cr alloys. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 284. OWE-CHL (29)

Applying Creep Stresses to Oil Still Tubes. R. S. Brown. *Petroleum Engineer,* Vol. 2, Midyear 1931, pages 137-138.

Special considerations entering into the application of stresses to still tubes and tube supports. Also some suggestions on the manner in which available data should be used. (29)

High Temperature Tensile Properties of Rail Steels. *Metallurgist,* Sept. 1930, pages 134-136; Oct. 1930, pages 147-149.

A review consisting primarily of an extended abstract of *Research Paper* No. 164 by Freeman & Quick on "Tensile Properties of Rail and Some Other Steels at Elevated Temperatures." See *Metals & Alloys,* Vol. 1, June 1930, page 565. VVK (29)

Nickel Chromium Alloys. *Electrician,* Vol. 107, Nov. 27, 1931, pages 718-720.

Methods of manufacture and physical properties at high temperatures are discussed. Forging and rolling, cold working and mechanical properties are included. WHB (29)

Destruction of Chrome Nickel Heating Elements. *Chemical Age,* London, Vol. 23, Dec. 6, 1930, Metallurgical Section, pages 33-34.

An extended abstract from a contribution of the Research Department of the Steatit-Magnesia A. G., Berlin. The causes of the destruction of the nickel chrome and other resistance wires used for electrical heating is the subject of an extensive series of tests resulting in the following conclusions. "The well known burning out of heating elements, a frequent source of trouble, is caused by the wire. Heating wires must obviously be treated much more carefully and considerately than is generally the case. The colored deposits occurring so extensively without the chemical or electrolytic coöperation of the ceramic material serve as a proof that overheating has taken place. When it is a question of the supply of radiating heat, a glowing temperature of 900° F. should be sufficient, and resistance wires and strips heated to much lower temperatures should be employed where only low temperature heating is required. If an arc occurs on the burning out of the heating wire, the ceramic element is also injured by the action of the oxides. The actual conductivity at high temperature of the ceramic material has much less importance than has hitherto been assumed." VVK (29)

Keeping Duralumin Rivets Workable in Dry Ice. E. P. Dean (Boeing Airplane Co.). *Metals & Alloys,* Vol. 2, Sept. 1931, page 165.

The forming properties of quenched duralumin rivets remain satisfactory for only very short times at room temperatures due to ageing; this has led to the method described of keeping them in boxes refrigerated by dry ice until they are used. WLC (29)

Quick Method of Determining Creep Strength. *Iron & Coal Trades Review,* Vol. 123, Nov. 27, 1931, page 831.

The creep limit is the maximum load which a material will stand at any given temperature under which the initial stretch gradually comes to an end. The determination of this limit requires a very long time. Pomp and Enders propose a practical method for quickly determining the creep resistance of steels. Short-time tensile tests are first made to determine the stresses which give permanent elongations of 0.01, 0.1 and 0.2%, respectively. Then the test pieces are subjected to steady loads corresponding to these stresses; the average rate of extension/hr. between the fifth and tenth hrs. is plotted for each of these loads. From the curve so obtained, the stress to give the specified extension of 0.003% /hr. during this period can be obtained. For more definite information, the tests should be extended another 40 hrs. with this stress under which the average extension between the 25th and 35th hrs. should not exceed 0.0015%. The results so obtained agreed very well with those of long-time tests extending over 2400 hrs. at from 300° to 500° C. Ha (29)

REDUCTION METALLURGY (31)

A Study of the Reducing Sintering of Powdered Iron Ores. G. Yamada. *Proceedings World Engineering Congress,* Tokyo, 1929, Vol. 33, published 1931, *Mining & Metallurgy,* Part 1, pages 497-531.

In English. Includes discussion. Various fuels were used for the sintering of a magnetite of 61.6% Fe, 14% SiO_2, with over 90% of the ore passing 150 mesh. The study also included examination of Bethlehem Steel Co., Greenawalt, and Swedish Greenawalt sinters, Manchurian Dwight & Lloyd Sinter, Manchurian Groendal briquets and commercial Japanese nodulized material. Analyses, strength, porosity, magnetic analysis and microstructure are given. The Japanese magnetite concentrate does not sinter well in an oxidizing atmosphere at 1350° C., but with 3 to 5% flue dust, anthracite or coke breeze, it sinters under 1150° C. through formation of the eutectic of ferrous oxide and ferrous orthosilicate. In discussion, E. Brauns expressed preference for coke breeze over anthracite. HWG (31)

Some Features of Lead Blast-Furnace Operations at the Works of the Broken Hill Associated Smelters Proprietary, Limited, Port Pirie, S. A. O. H. Woodward. *Bulletin, Institute of Mining & Metallurgy,* No. 321, June 1931, 27 pages; No. 326, Nov. 1931, 11 pages; *Proceedings Australasian Institute Mining & Metallurgy,* June 30, 1931, pages 57-86.

ZnO in the charge to the Pb blast furnace is the chief factor in the formation of shaft accretions, which upset the smooth operation of the furnace. When smelting such a charge the maintenance of a good smelting rate is essential. This is largely dependent upon the relationship between porosity and general average size of coke pieces. Coke must reach the tuyere zone; excessive accumulations of coke above the tuyeres lead to an intensely reducing atmosphere and high temperature at the tuyeres which causes Zn to distill from this zone and condense in the upper portion of the shaft. As coke accumulation continues the furnace slows up, the heat is driven further up the shaft, cementing action by ZnO is accentuated and the column ceases to sink. High CaO + high ZnO is undesirable and high FeO + MnO is desirable. To give good operation at Port Pirie the slag should show $(ZnO \times CaO)/(FeO + MnO)$ = less than 8.0 when SiO_2 is about 20%, 9.0 to 9.5 with SiO_2 about 22% and 7.0 to 7.5 with SiO_2 about 18%. When the tapping interval was 5 to 10 minutes, Pb in the slag was 2.26%; 10-20 minutes, Pb 1.93 %; 20-30 minutes, Pb 1.6%; more than 30 minutes, Pb 1.51%. The longer interval was possible only through raising the tuyeres. This also eliminated deep-seated accretions and prevented accumulation of coke above tuyeres. AHE (31)

Statistical Analysis of Blast-Furnace Data. Richard S. McCaffery & Ronald G. Stephenson. *Rolling Mill Journal,* Vol. 5, Mar. 1931, page 170.

A study of the effect of variation of slag composition on coke consumption, daily tonnage of pig iron, and S elimination. Abstract of a paper presented at the New York Meeting of the American Institute of Mining and Metallurgical Engineers, week of Feb. 16. See *Metals & Alloys,* Vol. 2, Apr. 1931, page 91. JN (31)

Blast Furnace Losses of Carbon by Solution and by Direct Reduction (Le perdite di carbonio per soluzione e per riduzione diretta nella loro importanza assoluta e comparativa). G. V. D. Mirandola. *Congres International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session Liege, June 1930, pages 87-93.

Discussion of the physical chemistry involved. 2 figures are given showing equilibria. HWG (31)

Sponge Iron Low in Impurities by Ekeland's Process. Correspondence from E. Oehman, Stockholm, Sweden. *Metal Progress,* Vol. 20, Oct. 1931, pages 89-90.

Reduction of ore with producer gas to sponge iron of high purity is described. WLC (31)

Hot Blast Furnace Problems. Wm. McConnachie. *Blast Furnace & Steel Plant,* Vol. 18, Dec. 1930, pages 1827-1828.

A study of the removal of the O from the ore and the part played by the gases produced in combustion. Ha (31)

The Importance of the Cyanides in Iron Smelting. W. McConnachie. *Iron & Steel Industry & British Foundryman,* Vol. 4, Sept. 1931, pages 396-398.

Utilizing data of former investigators, the author deduced that cyanides are formed below the tuyere level in the blast furnace in amounts equal to at least 200 lbs./ton pig iron produced. Since 200 lbs. KCN will remove the O from the Fe in about 300 lbs. pig iron, its presence is of great importance in the furnace. CHL (31)

Carbon in the Blast-Furnace Well. Wm. McConnachie. *Blast Furnace & Steel Plant,* Vol. 18, Oct. 1930, pages 1629-1630.

From available data on the role of C in the different parts of the blast furnace, some conclusions are drawn with regard to the heat requirements of the furnace; this field is not yet sufficiently elucidated. Ha (31)

Method for Computing a Blast Furnace Charge (En Beskickningsberäkningsmetod). Arvid Johannsen. *Jernkontorets Annaler,* Vol. 115, May 1931, pages 230-236.

The principle of the calculation, which is used for the students in Royal Polytechnical College (Sweden), is to determine for each ore its excess or deficiency of pure $CaCO_3$ for the formation of slag of a given silicate content. The necessary lime and silica is then computed from these values. The advantage of the relatively simple method is its rapid application in daily practice. HCD (31)

The Blowing-In of Blast Furnace Dust into Blast Furnaces according to the Heskamp Method (Das Einblasen von Gichtstaub in Hochöfen nach dem Heskamp-Verfahren). R. Milden. *Stahl und Eisen,* Vol. 51, Sept. 10, 1931, pages 1133-1135.

According to the Heskamp method, the dust is accumulated in a vessel and blown from there into the shaft of the blast furnace by means of compressed blast furnace gas of 4-6 atmospheres pressure. The proper height of the nozzles blowing-in the dust must be determined by experiment. In comparison with the sintering of blast furnace dust, the direct blowing-in into the furnace offers the advantage of a small first cost and small costs of operation. The operation of the blast furnace is not unfavorably affected by this method. GN (31)

Modern Blast Furnaces in Belgium. *Iron & Coal Trades Review,* Vol. 122, Jan. 9, 1931, pages 37-39.

A few examples of post-war construction and the details of design are given for units up to 1100 tons/day. Ha (31)

The Use of Limestone in the Iron and Steel Industry. OLIVER BOWLES (U. S. Bur. of Mines). *Rolling Mill Journal,* Vol. 5, Feb. 1931, pages 87-90; Mar. 1931, pages 167-170.

The metallurgical industries use 23,000,000 tons of limestone annually. 90% of this is used in blast furnace practice and most of the remainder in basic open-hearth steel furnaces. It requires 900 lbs. of limestone to produce one ton of pig iron. The chief impurities in both limestone and iron ore are sand and clay. S is also encountered, either in the ore or in the coke. The "available carbonate" in a limestone is determined by chemical analysis. About one lb. of lime (CaO) is required to neutralize one lb. of mixed silica and alumina. Dolomites, which yield lime and magnesia, are widely used in England in place of limestone. For high sulphur ores, a high calcium limestone is preferable. A good average limestone should contain less than 0.5% S and less than 5% total impurities. Sizes of lumps usually range from 4½ to ½ in. In average practice, about ½ ton of slag is formed/ton of Fe. Much of this is employed in road material, in concrete mixes, and in the manufacture of Portland cement.

Part II. The purpose of a limestone flux in the basic open-hearth furnace is to remove P and S. (The phosphatic slags obtained are used as fertilizers.) The avoidance of impurities in the limestone is much more important here than in blast-furnace practice, because of the difference in composition of the slag. Specifications are more rigid: silica must not exceed 1% and alumina 1.5%. A high calcium content is preferred and magnesia must not exceed 5%. The requirements as to particle size vary, but fines under 2 in. are usually excluded. Dead-burned magnesite ($MgCO_3$) and dead-burned dolomite ($MgCO_3+CaCO_3$) are both used for lining furnace bottoms, although the use of dolomite is generally confined to repair work. JN (31)

Vieille-Montagne Procedure in Super-Roasting Blendes. (Super-grillage des blendes, procédé de la Vieille-Montagne.) J. DE BELLEFROID. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 469-470.

By roasting down to 0.3-0.6% S, recovery of zinc from blende is increased 4 to 5%. The super-roasted material is 10 to 20% more dense, hence more can be charged at once and production thus increased. HWG (31)

Economical Aspects of the 1000-Ton Blast Furnace. H. A. BRASSERT. *Blast Furnace & Steel Plant,* Vol. 19, Jan. 1931, pages 89-91, 98.

From a study of present conditions, the author concludes that, with certain improvements which he discusses, the 1000-ton furnace will be able to combine large production with economical operation which may even lead to larger outputs. Such furnaces of larger capacity will, however, be installed only in conjunction with smaller units in order to preserve a good flexibility of the plant necessary for times of reduced demand. Ha (31)

Manganiferous Iron Ores and Their Influence on the Production of Iron and Steel in Australia. *Chemical Engineering & Mining Review,* Vol. 23, July 6, 1931, pages 381-382.

Australian iron ores consist of high-grade hematite with some of the ore richer in Mn. These ores are easily graded separately, making it easy to maintain regular supplies of manganiferous iron ores for use as charged ore in the steel plant. The advantages of high-manganese iron ore charges are indicated. WHB (31)

The Rotary Process of Extracting Metals. E. GOSSOW. *Engineering Progress,* Vol. 12, Jan. 1931, pages 20-21.

A "rotary" process of extracting metal economically from low grade ores is described. It is especially suitable for Zn. The raw material is continually fed, mixed with proper additions, fuel, etc., into the rotary kiln. Reduction and oxidation of the Zn may be made so as to coincide, as to time and space, so that both processes take place as a single thermic event. Installation and operation of a plant are described. Ha (31)

Mining Arsenical Ore in Sweden. OSCAR FALKMAN. *Engineer,* Vol. 152, July 24, 1931, page 96.

Translated from *Skandinaviska Kreditaktiebolaget.* Describes smelting plant started at Rönnskär in 1928. The ore is obtained from a deposit at Boliden discovered by electrical prospecting in 1925. The ore is a mixture of arsenical and iron pyrites containing Cu and Au. The Cu content averages 2% and the As 10%. Due to the high content of As, the usual smelting method is modified. The ore is crushed and goes to mechanical roasters for the removal of the As. Gases from the roasters are cooled to the point at which As condenses. Part of the As is settled out and the remainder is recovered in electrical precipitators. As is now being used for preservation of timber and of concrete constructions. LFM (31)

Economies in Blast-Furnace Operation. J. P. DOVELL. *Blast Furnace & Steel Plant,* Vol. 19, Jan. 1931, pages 118-120.

The article enumerates and explains some of the fundamentals on which successful practice is dependent such as hot blast, distribution of gases, preparation of raw materials. Ha (31)

Rationale of Dry Blast in Iron Smelting. W. MCCONNACHIE. *Iron & Steel Industry & British Foundryman,* Vol. 4, Apr. 1931, pages 223-225.

Dry blast requires less fuel than is necessary with ordinary blast. The hypothesis advanced by J. E. Johnson, Jr. to account for fuel economy is far from satisfactory. The author believes that a possible difference in temperature explains the economy in fuel reported. The temperature in the upper part of the furnace run on dry blast is lower than when ordinary hot blast is used and, therefore, a greater amount of C is deposited in this region. With favorable temperature conditions, sufficient C is deposited from the CO of the gas to directly reduce the ore. This will make for economy in fuel. CHL (31)

NON-METALLIC COATINGS FOR METALS & ALLOYS (32)

Special Lining of Pipe Insures the Retention of Carrying Capacity of Cast Iron Mains. ALEXANDER POTTER. *Water Works Engineering,* Vol. 84, Nov. 4, 1931, pages 1545-1546, 1567.

The economic life of cast iron mains must be based, not on the long life of the pipe, but upon the value of the carrying capacity of the pipe, assumed for the economic design period. By providing for a greater maintained carrying capacity through the use of interior lining throughout the system, it is possible to use pipes of smaller diameters and thus lessen the cost. Pipes centrifugally cast or spun with a bituminous lining have given excellent service with savings in the distribution system. The bituminous enamel is a solid material manufactured from a purified coal tar base and other ingredients, such as gums and fillers. It is melted to a liquid consistency and applied at a temperature of 400° F. to 415° F. The material sets in less than one minute. CBJ (32)

Explosions in Drying Ovens; Spontaneous Ignition of Vapors of Solvents (Explosionen in Lacktrocknungsöfen; Selbstentzündung von Lösungsmitteldämpfen). FREITAG. *Oberflächentechnik,* Vol. 8, Oct. 20, 1931, page 217.

The solvents for varnishes, lacquers, paints, etc., used in the metal industry are often the cause of explosions in the drying ovens because of the evaporation of the solvents and their coming into contact with the over-heated metals of the oven, itself. The ignition temperatures vary according to whether the vapors come in contact with metal or with glass. For the following frequently used solvents, the respective inflammation points are:

Solvent	With Glass	With Steel
Aceton	633° C.	649° C.
Benzol	580° C.	649° C.
Butylalcohol	356° C.	349° C.
Ethylether	188° C.	193° C.
Alcohol	421° C.	392° C.
Methanol (Methylalcohol)	475° C.	474° C.
Isopropylalcohol	457° C.	634° C.
Oil of turpentine	252° C.	262° C.
Toluol	553° C.	—

Ha (32)

Paint Coatings on Ships (Betrachtungen über Schiffsanstrich). M. RAGG. *Korrosion und Metallschutz,* Vol. 7, July 1931, pages 158-163.

The 2 problems involved in paint-coatings for maritime uses below the water-level are stressed: (1) rust protection, (2) anti-fouling means. An exhaustive information of the author's experience gained over a long period of years is given and refers to laboratory tests as well as to observations under actual service conditions. The numerous poisons applied and their usually negative effect are discussed. The nature of the various organisms found at the ship's bottom are considered at length. The author arrives at the conclusion that the inorganic Cu and Hg-compounds which have long been utilized could not yet be advantageously substituted in spite of the fact that the pre-war price of the latter increased 50% and 300%, respectively. The paper was presented at the General Meeting of the Reichsausschuss für Metallschutz, Kiel, 1930. EF (32)

Paint Sections and Surface Protection by Painting (Farbquerschnitte und Oberflächenschutz durch Anstriche). M. WILLMER. *Oberflächentechnik,* Vol. 8, Aug. 4, 1931, pages 161-163.

In order to discover the constitution of a coat of paint, a section is made through the whole layer of filler, ground color and top layer. This section is examined under the microscope. These investigations have shown that the surface of a good lacquer or varnish must be able to show a thin, clear film with a high polish. Nitro-lacs, especially, possess this quality; if it is destroyed by weather influences, they can again be polished with a suitable polishing agent. The thickness of the coat of paint, alone, does not assure its good quality. Several photographs illustrate these points. Ha (32)

What Should a Foundry Man Know of Enameling of Cast Iron (Was muss ein Giessereifachmann von der Gussemaillierung wissen)? JOH. WISSER. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Aug. 28, 1931, pages 686-688.

The author describes the preparation and application of the enamel and the treatment of castings for obtaining a perfect enamel coating. He also discusses the possibilities of failures and their causes and elimination. The expansion coefficient is of great importance; it should be, as nearly as possible, the same for the cast iron and the enamel. A good composition for cast iron which is to be enamelled is given as containing up to 3.5% C, 2.2-2.5% Si, 0.5-0.9% P, 0.6-0.9% Mn and not more than 0.1% S. The design of a piece also has an influence since greatly varying sections prevent uniform melting of the enamels. Ha (32)

Enameling Mechanized on Counter-Flow Principle. W. O. OWEN (Surface Combustion Corp.). *Iron Age,* Vol. 128, July 2, 1931, pages 16-17, 53-54.

Describes installation at the plant of the Peerless Enamel Products Co., Belleville, Ill. The plant operates on a mass production basis. The layout involves duplicate runs through the furnace with heat interchange between cold incoming and hot outgoing parts. Heat is saved and handling is facilitated by the arrangement of furnace dryers, dip tanks and spray booths. VSP (32)

Decorating the Surfaces of Precious Metals with Enamel. J. W. WOLFE. *Metal Cleaning & Finishing,* Vol. 2, Nov. 1930, pages 981-984.

Outline of the history and application of decorative enamels. Au is the best metal for this purpose. The purer the Au, the less are the chances of failure of the enamel. Presence of an oxidizable element such as Ag or Cu is likely to lead to reactions between the enamel and these metals. Transparent, translucent, opaque enamels are the types used. Hard enamels are preferable although more difficult of treatment. Gives formulas for producing various colors. MS (32)

MANUFACTURERS' LITERATURE REVIEWS

In this department we each month list the catalogs and other printed matter issued by manufacturers. Unless otherwise noted, any of the items listed may be secured free upon application to the issuing firm. Manufacturers who have not yet sent in their printed matter are invited to do so.

301 **Metal Testing**—Several metal testing devices are discussed in a folder prepared by Riehle Bros. Testing Machine Co., Philadelphia, Pa. They are: A precision hydraulic universal testing machine, a Vickers pyramid hardness tester, a Brinell tester and the Spekker steeloscope. A special booklet devoted to any of these machines may be procured from the company.

302 **Dowmetal**—This is the name which identifies magnesium alloys developed and manufactured by the Dow Chemical Company, Midland, Mich., and they have recently sent out a small booklet which gives the properties and applications of these alloys.

303 **Alloy Steel Castings**—An attractive pamphlet prepared by the Duriron Co., Inc., Dayton, Ohio, sets forth the physical properties of their "Durimet" and "Durco Nirosta" together with their chemical analyses. A table of their resistance to various chemicals is included.

304 **Foundry Equipment**—The February issue of "Better Methods," published by Beardsley & Piper Co., Chicago, Ill., contains several interesting articles and a description of their new "Screenarator" for screening, aerating, mixing, blending and piling sand.

305 **Corrosion Resisting Alloys**—The Associated Alloy Steel Co., Inc., Cleveland, Ohio, is distributing samples of their "Nevastain RA," a steel alloyed with chromium, copper and silicon which is said to have excellent corrosion resistance together with unusual machining, drawing and forming properties.

306 **Metal Cleaning**—Instructions for using Yellow Label Annite, a special detergent for cleaning non-ferrous metals, have been sent out recently by the Quigley Co., Inc., New York. There are several brands of Annite, and the uses of each of them are given in the same booklet. This company has also issued a leaflet describing their "Q-Seal," a plastic expansive joint sealing compound for all industrial uses.

307 **Quenching**—E. F. Houghton & Co., Philadelphia, Pa., have compiled an 80-page booklet which explains in simple terms the structural changes that take place as the result of various heat treatments. It contains over 30 charts and photomicrographs and presents the results of many years of research on the structure developed by quenching.

308 **Arc Welding**—A leaflet describing their simplified arc welder with "Unitrol Dial" has been sent out by the Hobart Brothers, Troy, Ohio. Various types of the machines are illustrated.

309 **Burners**—A folder, punched for filing, describing industrial burners has been issued by The C. M. Kemp Mfg. Co., 405 Oliver St., Baltimore, Md. Cross section diagrams of their various types of burners and their fire checks are given. A folder discussing their carburetors is also available.

310 **Cutting Metals**—Ramet (tantalum carbide) closely approaches the diamond in hardness, has a tensile strength of 250,000 lbs./in.^{2} and withstands shock and impact remarkably well and can be ground to a fine cutting edge. The Fansteel Products Co., North Chicago, Ill., has issued an attractive leaflet describing this product which is offered in a wide range of styles and sizes which will be found adaptable to most turning operations.

311 **Strain Gage**—The Tuckerman optical strain gage for the precise measurement of tension and compression strains in hot and cold metal specimens and for the testing of riveted joints is discussed in a pamphlet sent out by the American Instrument Co., Inc., Washington, D. C.

312 **Grinding**—The December issue of "Grits and Grinds," published by the Norton Company, Worcester, Mass., contains a description of a radial truing device, an aid in producing accurate work. Another interesting article in this issue is entitled "Mirror Finish on Rolls."

313 **Aluminum Alloys**—A most attractive 63-page book prepared by the Aluminum Company of America, Pittsburgh, Pa., gives in concise form information concerning the physical and chemical properties of the aluminum alloys produced by them. It also contains tables showing the sizes of the basic commodities the company manufactures from these alloys.

Lindeweld Process Shown in Motion Pictures

The technique of the Lindeweld Process and its application in the construction of a 20-in. natural gas line are shown in full detail in a motion picture, "New Lindeweld Process for Pipe Line Construction," prepared and distributed by The Linde Air Products Company, New York, N. Y.

Contact Potential Difference between Iron and Nickel and their Photoelectric Work Functions. G. Norris Glasoe. *Physical Review,* Vol. 38, Oct. 1931, pages 1490-1496.
Specimens of electrolytic Fe and electrolytic Ni were outgassed by intensive heat treatment in high vacuum and the contact potential difference between them measured by the Kelvin null method. An apparatus is described by means of which the photoelectric long wave limits could be determined on the same specimens and under identical conditions as used for the contact potential measurements. The photoelectric long wave limits were determined in one case by using filters in the path of the light and in the second case by the method of plotting the photoelectric sensitivity curves obtained using monochromatic illumination of the metals. The results remained unchanged between 300 and 750 hrs. of heating in the first case and between 400 and 600 hrs. in the second. The equilibrium value of the contact potential difference was Fe-Ni = 0.21 ± 0.01 volt. The photoelectric long wave limits determined by the second method were 2620 A.U. ± 10A.U. for the Fe and 2500A.U. ± 10A.U. for the Ni. The corresponding work functions are 4.71 ± 0.02 volts for the Fe and 4.93 ± 0.02 volts for the Ni. Using the method published by Fowler the work functions were 4.77 volts for Fe and 5.01 volts for Ni. The difference in these work functions by either method is equal to the measured contact potential difference between the metals within the limits of error of the photoelectric measurements. WAT (1)

Change of Weight of Metals under Compression. V. Some New Experiments in Gravitation. C. F. Brush. *Proceedings American Philosophy Society,* Vol. 64, 1925, pages 36-50.
Cylindrical metal test pieces machined from castings very slowly cooled, are fitted in a screw compression device and the whole is counterbalanced by a similar device suspended from the other arm of a carefully shielded balance. Successive compressions are then applied to one specimen, and an increasing loss of weight is noted which is partly regained on release of pressure so long as the elastic limit of the material is not exceeded. For Al and some alloys the effect is pronounced, the loss being of the order of 1 in 50,000. The author considers that corrections for buoyancy are unnecessary, since the counterpoise is accurately of the same nature as the apparatus being weighed. The theory that the results are explained by the expulsion of occluded gases is considered untenable. Ha (1)

Bismuth. *Metallurgist,* Dec. 1930, pages 191-192.
A comprehensive review covering metallurgy, physical properties, uses and applications and the extrusion of bismuth wire. VVK (1)

The Zero Point of the Charge of Silver (Ueber den Nullpunkt der Ladung von Silber). M. Proskurnin & A. Frumkin (Karpow Inst. of Chem. Moskau). *Zeitschrift für physikalische Chemie,* Sec. A, Vol. 155, No. 1, June 1931, pages 29-40.
Two methods employed aimed at the determination of the adsorption effects originated at the contact between a degasified silver surface and an aqueous solution. The zero point of the charge of a pickled silver surface yielded ϵ_h = 0.51, which value is in fair agreement with previous determinations of other investigators. EF (1)

Metallography and Properties of Metals. Rare Metals and Possibilities of their Use in the Metal Industry (Metallographie und Eigenschaften der Metalle. Seltene Metalle und ihre Verwendungsmöglichkeiten in der Metallwirtschaft). *Metallwirtschaft,* Vol. 10, Mar. 6, 1931, page 190; Mar. 13, page 209; Mar. 20, page 227.
Gallium is found in small percentages in numerous minerals, especially in zinc blende in Oklahoma. In the Joplin district 80-140 g./ton of ore are found. It melts at 30° C. and boils at over 2000° C. Its use for high temperature thermometers in quartz glass is being developed. To prevent it from sticking to the quartz, oxides and impurities must be removed by treating with warm dilute HCl. Other possible uses are for optical mirrors and alloyed with Al for cathodes for metallic vapor lamps. *Germanium.* This element lies between Si and Zn in the periodic system. Its melting point is 910° C. and hardness 6.25 on Moh's scale. It resists acids and alkalies and is brittle similar to Si, but otherwise resembles Zn. It occurs in 5-7% in Argyrodite but is more cheaply obtained from Enargite. The dioxide has been used to some extent in medicine. 1.2-1.6% Ge in Al alloys such as duralumin increases the tensile strength and rolling properties. Glass made with GeO_2 instead of SiO_2 has greater strength and can be poured at lower temperatures. The high price of Ge, about $10 a g., prevents its further use. *Scandium* is one of the rarest elements and not much is known of its properties. It is similar in some respects to the rare earths, in others to the Fe group. It melts at about 1200° and boils at 2400° C. *Indium* melts at 155° and boils at 1450° C. It can be obtained electrolytically, is readily soluble in HNO_3, less in HCl and H_2SO_4. Small percentages are found in zinc blende and other minerals, usually with Ga and Ge. A bearing metal containing 0.5-3.5% In has been patented. *Titanium* occurs in large quantities in the earth's crust, but has become important only in the last 10-15 yrs. It melts at 1800-1850° and is hard enough to scratch quartz. It is brittle at room temperature, but can be forged and drawn at red heat. It combines directly with most non-metals under heat and forms alloys with many metals. It is recovered from rutile, TiO_2, and ilmenite, $FeO.TiO_2$. Ti is used mostly as TiO_2 in white paint pigments. It has greater resistance to chemicals, covering power and durability. TiO_2 is also used in ceramics, for artificial teeth, and as a quick setting cement. Ferro-titanium containing 15-18% Ti and 7.5% C is made in the electric furnace. C-free ferro titanium is made by the thermit process. It contains 25% Ti and 5% Al and is more expensive than that containing C. They are used for the production of special steels. Ti-Cu containing 10% Ti and Ti-Mn containing 30% Ti are on the market and are used in small quantities for the deoxidation of brass, bronze, Ni and Cr alloys. Konel, an alloy of Fe-Ti, Co and Ni, is supposed to retain its strength at high temperatures and is used as a substitute for Pt in radio tubes. CEM (1)

Batterium Metal—a New British Anti-Corrosive Material. *Chemical Trade Journal,* Vol. 89, July 3, 1931, pages 5-6.
Batterium metal is manufactured by Batterium Metal & Voslok, Ltd. of Market Harborough, England, and was developed by the Research Department of the Tungstone High-Pressure Die Casting Co., Ltd. It is used as plate terminals of Tungstone car batteries and in the manufacture of the Tungstone pump. It is a natural alloy containing 89% Cu, 9% Al, and 2% Ni and other metals in specific proportions. It contains no Pb, Sn, Zn, or Sb. It possesses a silvery gold color. Its physical, chemical and electrical properties are indicated. A table shows the action of acetic, sulphuric and hydrochloric acids of various strengths, and of several sodium salts in hot and in cold solutions. WHB (2)

Carbobronze Tubing. *Industrial Chemist,* Vol. 7, June 1931, page 257.
Carbobronze (alloy containing about 92% Cu, 8% Sn and 0.3% P) is of dense structure and possesses great homogeneity. A strong resistance to the action of a wide range of acids and alkalies is claimed. RAW (2)

Bronze and Red Brass (Bronze und Rotguss). VDI-Verlag GMBH, Berlin NW 7, 1931. Paper, 6x8¼, 100 pages. Price 7RM.
The German standards (given in the appendix) for this class of castings include 10 alloys, but do not include 85-5-5-5, 88-10-2 nor 80-10-10, the alloys approaching these being 82 Cu, 8 Sn, 7 Zn, 3 Pb; and 85 Cu, 5 Sn, 7 Zn, 3Pb; 86 Cu, 10 Sn, 4 Zn; and 80 Cu, 8 Sn, 12 Pb.
Short articles by Schmidt, Schwietzke, Reiff, Krekeler, Reitmeister, Fiek, Vierhaus, Riccius, Melchior, Schulz, Hennings, Bay and Claus are given, with discussion. Starting with the Cu-Sn equilibrium diagram, the structure of various compositions at various cooling rates is discussed, then the influence of the addition of Zn.
A questionnaire to 70 German firms in 1930 brought out the fact that 29 paid practically no attention to the standards, and while 15 of the firms make 60% of their production in the standard alloys, of the whole 70, only 20% of the output is according to the specifications.
It was pointed out that the specification limits as to impurities, especially Pb and Sb, made it difficult to use secondary ingot for some of the compositions and live up to the specifications.
Several comments in the discussion indicated that the alloy 82 Cu, 8 Sn, 7 Zn, 3 Pb was little used, and might be eliminated from the standards.
The machinability of the alloys and the use of cutting oils and emulsions were discussed, as were the effects of oxides, S and of over-reduction.
Melchior advocates the use of Be as a deoxidizer for copper castings when high electrical conductivity is desired. Bay reports materially improved properties on annealing the alloy of 86 Cu, 14 Sn.
Many interesting comments were brought out in the general discussion whose reproduction here would extend this abstract too far. Non-ferrous foundrymen will find the whole pamphlet of interest. H. W. Gillett-B-(2)

Special Complex Brasses (Les laitons complexes). Leon Guillet. *Cuivre et Laiton,* Vol. 4, Nov. 15, 1931, pages 501-503.
Several types of brasses and bronzes are described. The addition of Al and Si together should be avoided; Al and Mn together do not develop any better quality than one of these elements, alone, can produce. The presence of Ni produces very good effects in complex brasses; for example, the following composition shows very good mechanical properties: Cu 58%, Zn 31.15%, Ni 7.45%, Al 3.4%. It can be forged readily; it is not difficult to pour; it has as high resistance to corrosion as any good alloy known. The resistance to repeated impacts is somewhat higher than that of mild annealed steel. Heat treatment does not give a noticeable improvement; these alloys can be used as they are cast. They are easily machined. Ha (2)

The Electric Conductivity of the Gold-Nickel Alloys (Die elektrische Leitfähigkeit der Gold-Nickellegierungen). G. Grube & F. Vaupel. *Zeitschrift für physikalische Chemie,* Bodenstein Festband, 1931, pages 187-197.
Temperature-resistance curves were plotted over the temperature range from 20° to 900° C. with the object of investigating the reactions associated with the decomposition of the homogeneous solid solutions of the Au-Ni alloys. The conclusion is drawn from the data obtained that the homogeneous solid solution decomposes into a heterogeneous mixture of solid solutions one kind of which is rich in Au and another which is rich in Ni. The decomposition is caused by the decrease in solubility of the components at falling temperatures. The boundary line separating the field of homogeneity from that of heterogeneity is established and presented in a diagram. No indication of 2 eutectoid horizontals assumed by Heike and Hafner (Doctor's thesis, Freiberg, and *Zeitschrift für anorganische Chemie,* Vol. 182, 1929, page 272) was found whereas the results are in fair agreement with the findings of Fraenkel and Stern (*Zeitschrift für anorganische Chemie,* Vol. 151, 1926, page 105; Vol. 166, 1927, page 161). EF (2)

Copper Alloys Containing Silicon. *Chemical Age,* London, Vol. 22, Jan. 4, 1930, Metallurgical Section, pages 1-2.
A review of 11 references. VVK (2)

Everdur and Tempaloy. W. H. Bassett. *American Metal Market,* Vol. 33, July 2, 1931, page 2.
2 kinds of hardened copper, the former varying from 94.8% Cu, 4% Si and 1.2% Mn for castings to 96.0% Cu, 3% Si and 1% Mn for wrought forms and castings. Everdur can be forged and rolled hot but will not stand much cold working. Excellent corrosion resistant material. Tempaloy is copper carrying nickel silicide; when heated to 800° C. and chilled, it is soft and ductile, and can readily be cold worked. It may be age hardened when alloy is held at 450° C. for a few hours; without cold working, or after cold working, addition of Al strengthens Tempaloy and increases its hardening properties. DTR (2)

PROPERTIES OF FERROUS ALLOYS (3)

Non-Magnetic Cast Iron (Nichtmagnetisches Gusseisen). *Elektrotechnische Zeitschrift,* Vol. 52, May 7, 1931, page 612; *Revue de Fonderie Moderne,* Vol. 22, Sept. 25, 1928, page 378.

This material called "Nomag" is made by the Ferranti Works, Hollinwood, Lancashire, England and has the following characteristics:

	Highest magnetic permeability	Spec. resistance $\mu\Omega/cm.^2$
Ordinary cast iron	330.00	95.00
Brass	1.00	7.50
Nomag iron	1.03	140.00

The material is ,therefore, particularly suitable for resistance grids. It is as easily cast as cast iron and can be Ni, Cu or Cr plated. It is, also, just as easily machinable and can be welded. Ha (3)

On the Properties and Utilization of Ni and Cr-Ni Steels (Ueber die Eigenschaften und die Verwendung der Nickelstähle und Chrom-Nickelstähle). J. Galibourg. *Korrosion und Metallschutz,* Vol. 6, Sept. 1930, page 206.

A few tentative specifications are also reprinted in detail. Ha (3)

Magnetic Properties of Some Nickel-Iron Alloys. *Metallurgia,* Vol. 5, Nov. 1931, pages 1-3.

Bibliography of 17 references. Attention is called to the wide range of magnetic properties that can be secured in Fe-Ni alloys. Those containing about 78% Ni have a very high initial permeability and a high permeability at low magnetizing fields. The properties can be modified by other elements such as Cu, Mo, Cr and Co. Some alloys containing Co (Perminvar) have an almost constant permeability over a rather wide range of magnetizing forces and a very low hysteresis loss. JLG (3)

Wear Resistance of Cast Iron (Verschleissfestigkeit des Gusseisens). *Zeitschrift Verein deutscher Ingenieure,* Vol. 75, Oct. Oct. 10, 1931, page 1274.

A testing arrangement is described by means of which the wear of high grade cast iron is tested, as dependent on hardness, on additions of C, Si, Mn, P, S, Ni, Cr and Cr-Ni, on temperature and quality of surface. Not the absolute hardness, but the difference in hardness of the 2 materials working on each other, determines the wear. The wear is least when this difference becomes zero. A strict dependence on the absolute hardness can be stated only if both moving and stationary parts have the same hardness. The wear is determined to a certain extent also by the formation of graphite. Long, thin graphite veins reduce wear; coarse, thick veins and graphite eutectic increase wear. A content of P up to 1% increases the wear strength considerably; beyond that, but little. With increasing temperature, the wear depends greatly on the P content. The quality of the surface is of greater importance, the higher is the grade of cast iron. Very hard surfaces have to be smoothed by machining. Ha (3)

Wrought-Iron Pipe Nipples. *Commercial Standard CS 6-31, U. S. Department of Commerce, Bureau of Standards,* 1931, 14 pages.

A revision of the former standard of 1929. Pipe from which nipples are made must conform to A.S.T.M. Standard A72-30. Details of dimensions and threads and lists of stock sizes and lengths of standard weight and extra strong nipples are given. HWG (3)

Kanthal, Ltd., Hallsthamar, Sweden (Aktiebolaget Kanthal Hallsthamar). *Journal du Four Electrique,* Vol. 40, June 1931, page 241.

Kanthal is an electric-resistance alloy with an iron base and melting point of 1650° C. Its specific gravity is 7.2. The metal is suitable for use at temperatures near 1300° C., but the point of decomposition of its better grades was not reached at 1350° C. After heating for 800 hrs. at 1250° C. the metal has the same silvery gray appearance as before the experiment. Its heat-resistance both at high and low temperature is much better than that of 80% Ni and 20% Cr alloy. Several furnaces for quenching high speed steel have already been installed in Sweden and, after considerable use, show that the heating elements did not deteriorate. The metal is easily machinable. About a dozen installations of heat recuperators on oil burning furnaces have been in use for more than a year. A carburizing box in a continuous use at 950° C. was in a perfect shape after 2 years' use. The resistance to SO_2 gas is very good at all temperatures. Several grades depending on the heat resisting requirements are manufactured. JDG (3)

Alloy Steel Castings. *Vancoram Review,* Vol. 2, July 1931, pages 83-86.

A few of the recently developed V steels with Ni additions are discussed. Some with Mo and Cr which show very high elastic properties, resistance to wear and ability to render long continued service when exposed to loads suddenly applied are particularly discussed; the C content is between 0.2 and 0.3%. A series of V cast steels which combine high yield point, high tensile strength and high impact resistance are also described. For the various analyses and test results, the paper must be referred to. Ha (3)

CORROSION, EROSION, OXIDATION, PASSIVITY AND PROTECTION OF METALS & ALLOYS (4)

Corrosion of Metals under the Influence of Various Liquid Fuels (Korrosion von Metallen unter der Einwirkung von verschiedenen flüssigen Brennstoffen). *Automobiltechnische Zeitschrift,* Vol. 34, June 10, 1931, pages 384-385.

A review of literature giving information on this subject. Benzene, as used in airplanes, has a corroding influence on Pb; other metals were not attacked and the benzene remained unchanged. Pure benzol, toluol and xylol do not attack; metals immersed in them receive deposits of a tar-like substance. Pb was corroded by alcohol; metals immersed in alcohol were not attacked but, if exposed to the vapors, were strongly attacked. Commercial alcohol attacked all metals; likewise, methyl alcohol. The nature of the deposits is described and the loss of material in mg./dm.^{2} surface is tabulated for all the fuels investigated. Ha (4)

Broken Rivets Indicate Caustic Embrittlement. *Boiler Maker,* Vol. 31, Feb., 1931, pages 45-46.

If the quantities of soda ash and lime for treating the feed water are not regulated in keeping with the nature of the water, the danger exists that an excess will be present, and rivets become brittle. Several cases in which this was the obvious cause are noted. Ha (4)

Prevention of Boiler Corrosion in Storage. *Boiler Maker,* Vol. 31, April, 1931, pages 92-94.

Abstract of the report on protection of boilers and boiler materials from corrosion and deterioration while in storage. Best methods are recommended; racks, sheds, oiling, etc., are discussed. Ha (4)

Methods for Determining the Corrosion Resistance of Aluminium and Aluminium Alloys. *Industrial Chemist,* Vol. 7, Sept. 1931, pages 378-380.

A translation of the "Tentative Standards elaborated by the Aluminum Board of the German Reichsausschuss für Metallschutz." The article describes the taking of the specimen from the sample sheet, number, size, and preliminary treatment of the specimens, as well as discussing the evaluation of the results. Special directions for the performance of the tests and the use of an apparatus for corrosion tests in stirred solutions are given. RAW (4)

Results of Questionnaire to the Chemical Industry Concerning Experience with Aluminum Applications (Material-Prüfungs-und Untersuchungswesen Nachtrag Nr. 7 zum Ergebnis der Rundfrage bei den chemischen Fabriken über Erfahrungen mit Aluminium-Verwendung). *Apparatebau,* Vol. 41, Sept. 6, 1929, pages 205-208; Sept. 20, 1929, pages 220-222.

A report of the corrosive action of several chemicals on Al. Reports are given for (1) aceticanhydride, (2) caustic soda, fortified with bichromate, (3) ammonium nitrate, (4) ammonium sulphate, (5) acetic acid, (6) honey, (7) O, and several other conditions with varying acidity and alkalinity. Corrosion of Power Plant Equipment. *National Engineer,* Vol. 35, Sept., 1931, page 296.

A study was made to discover what factors usually contribute to the corroding effects of flue gases. It is stated that corrosion is most often present when the S content of the coal exceeds 2%. Corrosion in pulverized fuel systems is never severe, even when the same fuel produces corrosion when fired on a stoker. High ash coals, especially under high draft, produce corrosion in most cases. The zone of maximum corrosion is usually that immediately in front of the air intake on the air preheater. The highest metal temperature at which severe corrosion is encountered is about 300° F. Above this temperature, the slight corrosion is similar in extent and type to that which takes place in ordinary boiler tubes. Differences in type of construction of economizers and preheaters do not show great differences in the rate of corrosion. Protective metallic coatings have not withstood the attack. Enameled tubes will withstand corrosion if mechanical difficulties connected with their use can be eliminated. Ha (4)

Corrosion of Metals by Food Products. *Chemical Age, London,* Vol. 25, July 11, 1931, page 36.

A valuable compilation of existing data on the use of metals and alloys in contact with dairy products has been issued by the Kollegium der Preussischen Versuche- und Forschungsanstalt für Milchwirtschaft (*Milchwirtschaftlicher Literaturbericht,* No. 36, 1930, page 181). VVK (4)

Corrosion of Lead-Sheathed Cables (Beitrag zur Korrosion von Bleikabeln). G. GARRE. *Elektrotechnische Zeitschrift,* Vol. 52, Nov. 12, 1931, page 1418.

After 16 yrs., a failure occurred in a cable with pure Pb cover which contains only traces of Sb. A careful investigation showed the cause of the corrosion to be the effect and the presence of phenol in the impregnated paper insulation of the cable. Ha (4)

Conference on Exposure Tests of Plated Coatings. *Monthly Review American Electroplaters' Society,* Vol. 18, April 1931, pages 8-16.

This conference was to discuss a program for exposure tests on electroplated coatings which is to be carried out through the co-operation of the American Electroplaters' Society, the American Society for Testing Materials, the Bureau of Standards and the manufacturers interested. The 2 principal purposes of the investigation are (1) to determine the relative value for protection against corrosion of electroplated coatings of known composition, thickness and preparation; (2) to determine the relation of laboratory tests on such coatings to their protective value under different conditions of service. The tests to be made should include (1) accelerated corrosion tests; (2) porosity tests; (3) stripping tests; (4) adhesion tests; (5) exposure to corrosion while stressed. The order of tests, solutions and conditions to be used in plating, size, shape and arrangement of the specimens, preparation for plating, conditions of exposure, methods of inspection are described in detail. Ha (4)

Stainless Metals. HAROLD CARPENTER. *Iron & Coal Trades Review,* Vol. 122, May 1, 1931, pages 690-691.

A general review of corrosion phenomena, their causes and elimination, particularly in iron and steel by the addition of Cr; the effects of composition and heat treatment and the types of stainless steels now produced. Ha (4)

Corrosion Phenomena Observed on Copper-bearing Steels with Particular Reference to the Attack by Sea-Water (Der Korrosionsvorgang beim gekupferten Stahl unter besonderer Berücksichtigung des Angriffes durch Seewasser). C. CARIUS (Res. Lab. of Vereinigte Stahlwerke, Dortmund). *Korrosion und Metallschutz,* Vol. 7, Aug. 1931, pages 181-191. Includes discussion.

A lecture delivered before the Reichsausschuss für Metallschutz, Kiel, adding some further findings to statements previously published (See *Metals & Alloys,* Vol. 2, July 1931, page 127). The beneficial influence of Cu upon the corrosion resistance against atmospheric attack of low alloyed steels is summarized in the introduction. Although being contradictory, corrosion tests in liquid media did not yield the same marked advantages due to an addition of Cu. The various stages of the rusting process on copper-bearing steels (0.2-0.3% Cu) in distilled water is characterized by the formation of a dense Cu-film, which slowly oxidizes, flakes off and is again originated, thus retarding the corrosion speed of the same steel free from Cu. Entirely different conditions are met with in alkaline or salt solutions, mainly due to a spongy precipitation of the Cu. The potential of finely dispersed, atomic copper is assumed to be considerably less noble than the potential of Cu in crystalline form. The complicated reactions in aqueous salt solutions are traced in 2 set of samples (a) with access to air, (b) in sealed containers. The author arrives at the conclusion that a "sorption compound" consisting of Fe_2O_3 aq- and the basic Fe $(OH)_2+$ is formed. The varying amounts of Fe_2O_3 are responsible for the gradually changing colors of this compound. It might be mentioned that an experimental steel was melted which contained 0.2% Al instead of Cu to throw light upon the role played by the latter metal. The result of commercial significance is that the analysis of the copper-bearing steel was modified by a further addition of 0.11% Al to the 0.2% Cu, which is supposed to result in a fair corrosion stability in salt water, also. The New Immersion Method of the Research Institute Gmuend for the Protection of Silver and Silver-Plated Wares Against Tarnishing (Das neue Tauchverfahren des Forschungsinstituts Gmünd zum Schutze von Silver-und versilberten Waren gegen das Anlaufen; D. R. P. angemeldet). *Oberflächentechnik,* Vol. 8, Oct. 6, 1931, pages 207-208.

After long years of experimenting, a solution has been found which will entirely prevent tarnishing of any ware immersed in it. It can be cleaned, as is usual in the household, without being rubbed off. The nature of the solution is not disclosed. Ha (4)

Nickel and its Alloys in the Decorative Arts (Le nickel et ses alliages dans la décoration). *L'Usine,* Vol. 40, Sept. 18, 1931, page 27.

A brief enumeration of the alloys containing Ni which are used, either directly for the manufacture of decorative articles which must not rust, or as a rust-proof coating. Ha (4)

Grounding and Corrosion of Metals. (Erdungsfrage und Metallkorrosion). *Metallwirtschaft,* Vol. 10, May 15, 1931, pages 393-394.

Contribution from the German Copper Institute. Contains 4 references. Telephone lines and radios are frequently grounded on water or gas lines to overcome interference from weak electric currents. Grounding has often been blamed for corrosion of metals, but investigation has always proved that other factors are responsible. S in gas may be the cause of Cu water heaters corroding. For water lines, Cu is the only practical metal which does not corrode. Pb water pipes through which hot and cold water flows alternately may break due to change in crystal structure if the Pb is not pure. If Fe pipe is in contact with brass, Pb or Cu, electrolytic currents of measurable size are produced which may be as high as 1 amp./m.[2] or higher with warm water. CEM (4)

High Steam Temperatures and Steel. *Metallurgist*, June 1931, pages 86-87.

This article is primarily an extended abstract of an investigation by Munzinger (*A. E. G. Mitteilungen*, Jan. 1930, *Das Kraftwerk*, page 26) on the cause of failure of superheater tubes with a brief summary of the work of Fellows (*Power*, page 258, 1929). The instigation of Munzinger's work was the failure of a number of superheater tubes in a boiler plant operating at 320 lbs./in.^{2} steam pressure at a temperature of 425° C. The superheater had proved to be entirely too large for the purpose and after repeated removals for covering was finally operating at about 60 to 70% of its original capacity. After about 4 months' operation under various burdens, a number of tubes were burnt through. There was a fairly large deposit of iron oxide inside the tubes and the outside was more or less oxidized. Opposite to a blister, a horn shaped very solid deposit consisting of chloride and soda had formed. In some places the tubes were almost completely eaten away by internal corrosion, whereas places not attacked showed no diminution in strength. The corrosion on the inside of the tubes was more severe than on the flue gas side. It was considered improbable that the corrosion was caused by the dissociation of water vapor. As the heating surface of the superheater was too large, there was probably unequal attack on the individual coils, and the deposition of impurities carried over into the superheater caused a decrease of clear cross section which resulted in a higher temperature in some tubes than that measured at the superheater outlet. A reaction between the steam and tube thus resulted and was increased by the presence of chlorine compounds carried over with the steam. The A. E. G. Research Institute investigated the formation of the oxide layer at higher temperatures. A spiral of iron wire was heated in a silica tube and a stream of water vapor was passed through the tube. The progress of the oxidation of the wire was determined by measuring the electrical resistance, which increases as oxidation proceeds. The reliability of this method was tested by careful preliminary experiments, and results were confirmed by comparison with the increase in weight due to the formation of oxide. The results indicate that, after reaching an approximately constant rate, the rate of oxidation at 610° C. is about 5 times that at 500° C., and after about 360 min. at 500° C. there is scarcely any further increase in resistance, while the increase at 610° C. is still very pronounced. This is regarded as indicating that at the lower temperature a protective oxide layer is formed after a certain time, but at the higher temperature the formation of a protective layer is improbable. This result suggests that, in ordinary mild steel tubes, there is a critical temperature in the neighborhood of 500° C. above which the steel is rapidly attacked although feed water conditions are normal and attack by the hot flue gases is not appreciable. It is possible that free O in the feed water may contribute to the damage to the boiler, but the experiments indicate that, even with gas-free feed water, strong corrosion can proceed. Tests were also made on the mode and magnitude of attack by alkali and chloride carried over with the steam into the superheater. It is considered, however, owing to the varying conditions, that it is difficult to forecast the effects in the superheater from laboratory experiments, but it is extremely probable that alkali and chlorides considerably accelerate corrosion. The amount of corrosion observed in laboratory experiments may, under practical conditions, be increased by vibration of the superheater coils, temperature changes of the flue gas and erosive action of the steam, owing to the rupture of the protective oxide layer. A metallographic examination of the structure of the tubes from the German superheater indicated that at the damaged places the section had been weakened by corrosive action. At places where the tube had burst, the entire circumference was strongly attacked. At other places where cracks had formed, failure appeared to be due to both internal and external corrosion. There was also evidence of decarburization in sections cut from undamaged parts and an increase in grain size at the edge zones where the tubes had been subjected to cold bending during the manufacture of the superheater coils. It is almost impossible to estimate to what extent these changes in the structure of the steel were due to conditions existing prior to the failure of the tube. As a result of the investigation, it is concluded that the heating surface of the superheater was too large, and, in consequence, excessive steam and tube temperatures were attained. Deposits of salts in the tubes, by checking the flow of steam, probably magnified these temperatures. A strong reaction between the steam and steel tube was created. Although the outside of the tubes was overheated, there was much more corrosion on the inner walls. It is probable that the internal corrosion was accelerated by impurities carried over with the steam, and by free O in the feed water. It is possible also that the steam velocity was too low and, thus, all the tubes were not uniformly affected; some were insufficiently cooled by the flow of steam. The highest permissible temperature at the superheater exit for the normal operation of superheaters constructed of mild steel is given as 450° C.

Procedure in Making Surveys of Soils. Donald E. Dickey & H. Hayes (General Petroleum Corp. of California). *Oil & Gas Journal*, Vol. 29, June 5, 1931, page T-75.

The following procedure for soil survey work for pipe lines is suggested as a result of experience. (1) Careful selection of soil samples along pipe line right-of-way. (2) Record of topography, local conditions affecting soil, etc. (3) Comparison of right-of-way map with Government soil maps. (4) Measurement of soil resistivity. (5) Chemical analysis of more important soils. (6) Final selection of coatings for those portions of line where protection is necessary.

Progress in Surface Protection—Protection against Corrosion (Fortschritte im Oberflächenschutz Korrosionschutz). Georg Buchner. *Oberflächentechnik*, Vol. 8, Oct. 6, 1931, pages 205-207.

Protection of surfaces against corrosion can be obtained in 2 ways: (1) The surfaces are protected by the nature and properties of the material, itself, such as resistant metals and alloys; metallic and non-metallic materials can be distinguished. (2) The surfaces are protected by suitable change of the surface which is open to attack, for instance by protective coatings of various kinds and impregnation; here, also, metallic and non-metallic materials can be used. Whenever possible, a material of the first group should be used; only when this is impossible should the second group be resorted to. An enumeration of alloy acid-resisting steels, cast iron, materials possessing temperature resistance, especially Cr-Ni steels and their particular fields of application, are given. Of non-metallic materials, glass, porcelain, earthenware, rubber, especially ebonite with resistance to fluoric acid, must be particularly mentioned. In the chemical industry, a material, "prodorite," has found wide application. It is a cement-concrete with several additions, particularly pitches and special bitumins. Coatings are produced by dipping in molten metals, calorizing, alitizing and electroplating. Coloring can also give protection in certain cases. Case hardening, nitriding or phosphate coating is another type of protection. Non-metallic protection can be obtained by wood, cement, pitch, bakelite, paraffin, waterglass, paints.

Ghost of Sulfur in Gasoline Costs Americans 50 Millions a Year. Gustav Egloff, C.D.Lowry, Jr. & Paul Truesdell (Universal Oil Products Co.). *National Petroleum News*, Vol. 22, June 11, 1930, pages 41-43, June 18, 1930, pages 69-72, June 25, 1930, pages 79-80.

A survey of opinions and data in America and Europe on the question of automobile engine corrosion by S in gasoline. Tables of the S content of crude oils, gasoline and cracked gasoline are given. The author summarizes as follows. (1) No work has ever been published conclusively showing damage to automobile engines in actual use on the road from motor fuel containing more than 0.10% S (the present limit). (2) The supposition that such motor fuels do cause corrosion is based entirely on a few laboratory tests carried out at below freezing temperatures. The investigators who did the work and reported corrosion of wrist pins in their tests expressed the opinion that corrosion from S would not be a menace if all cars were equipped with crankcase ventilators which would prevent the condensation of moisture in the crankcase. These investigators, and all others who put themselves on record, have had little or no fear of corrosion when operating motors at temperatures above freezing. (3) over 70% of the gasoline used in this country is burned when the atmospheric temperatures are well above 32° F. and can, therefore, cause no corrosion. (4) A large and increasing number of the new cars coming out are equipped with crankcase ventilators. (5) Millions of gallons of gasoline are now being marketed in various parts of the United States, which contain 0.30% S, more or less, without any complaint of corrosion of engine parts. (6) Road tests of considerable extent, carried out by competent investigators with high S fuels under severe operating conditions have shown not a trace of corrosion. (7) No European country has any general S limit in its specifications for motor fuel either for automobiles or for aviation. So far as can be learned by questioning outstanding oil technologists in European countries, corrosion of automotive engines from S in the fuel is practically unknown.

Corrosion Phenomena in Ship-building (Korrosionserscheinungen im Schiffbau). M. P. Andreae. *Korrosion und Metallschutz*, Vol. 7, June 1931, pages 125-133; Discussion, pages 133-134; *Metallurgist*, Sept. 1931, pages 140-142.

The paper presented at the General Meeting of the Reichsausschuss für Metallschutz, Kiel, details the experiences gained on the various kinds of corrosion attack on ocean-liners and outlines the methods of corrosion prevention. The following localities subject to corrosion are considered: (1) Parts of the stern. Cause, whirl of water + air. Opinions divided. Prevention by zinc plates. (2) Central parts of the hull, mostly rivets. Cause, uncertain. Prevention by effective paint-coating. (3) Tanks on tankers. Cause, benzine. No effective protection as yet. (4) Screw. Source, corrosion + erosion checked by utilization of special naval bronzes, brasses, proper design, dense castings. (5) Propeller shaft. Protective cover of bronze and rubber. The second part of the paper deals with the corrosion encountered in various parts of the machinery. Passing mention is given, however, only to the generally known condenser tube corrosion. A great variety of materials is still applied for ship piping and the experiences of the various ship yards are very contradictory. Recent tests on turbine pumps are described, the difficulties involved in the cooling of Diesel-engines are stressed, the corrosion of pistons and piston-rods is considered and the new problems to be solved on motor-ships are set forth. The third part of the paper pertains to heat-resisting materials employed for fire-places, waste-gas pipes, pre-heated tubes. After summarizing the experiences gained on various materials used for fittings, which are principally exposed to the attack by spray and atmospheric influences, the speaker reviews the different corrosion protection means brought on the market and outlines the significance for maritime purposes. Among the great number of corrosion resistant metals and alloys applied in ship building, the behavior of stainless steel recently used tentatively is emphasized.

Resistance of Copper-Nickel Steels to Sea Action. J. Newton Friend and W. West. *Iron & Coal Trades Review*, Vol. 123, July 3, 1931, page 1.

Samples containing up to about 4% Cu were cast and annealed at 920° C. and exposed to sea action for 2 yrs.; after that, a micrographic examination was made. The most resistant of the samples contained 1.16% Cu and 3.75% Ni; it lost least in weight and its general surface was free from pitting and had a fine structure. See also *Metals & Alloys*, Vol. 2, Nov. 1931, page 248.

STRUCTURE OF METALS & ALLOYS (5)

Metallography & Macrography (5a)

Physical Metallurgy Laboratory Manual. NORMAN E. WOLDMAN. Wiley & Sons, Inc., New York, 1930. Cloth, 6x9, 259 pages. Price $3.50.

The author gives as the purpose of this book "to meet a growing demand for a well illustrated laboratory manual and reference book in the metallography and heat-treatment of ferrous and non-ferrous metals and alloys." It could hardly be expected that any book of only 259 pages, a large number of which are illustrations, could adequately fill the requirements of both a laboratory manual and a reference book. It is difficult to fulfill both purposes without resorting to a more lengthy thesis. We presume that the second volume "Theoretical Physical Metallurgy" which is to be issued will contain all that the first volume lacks from a reference standpoint. The inclusion of such material as a thorough discussion of the fundamentals of the microscope, of high power metallography and X-ray examination should be left to the reference book where the discussion can be made sufficiently comprehensive to be of some value. The illustrations are excellent. Possibly they could be made of greater usefulness to the student if the descriptions were immediately under the photomicrographs. The field covered is quite broad. Among the subjects illustrated are the commercial irons and steels; cast iron; heat-treatment of steels; alloy steels; case-hardening, carburizing and nitriding; brasses and bronzes and the effect of mechanical working and heat-treatment upon them; aluminum and its alloys; bearing metals; welding, brazing and soldering; and defects and failures in metals. The chapter on defects and failures in metals is not sufficiently informative for the student. In some cases the history of the failure could be given in more detail and in others photomicrographs of the normal structure of the steel should be given alongside that of the defective material. However, there is much information of real value in the book and it should prove of considerable usefulness. V. V. Kendall (5a)-B-

Is a Change in Solid Solubility a Liability or an Asset? E. M. WISE. *Mining & Metallurgy,* Vol. 12, June 1931, pages 270-272.

The third of a series of articles contributed by the Institute of Metals Division. The Fe-C system affords a most important example of the value of a change in solid solubility. By cooling an Fe-C alloy containing C in solution at sufficiently high rate, an alloy enormously supersaturated with respect to C can be secured. Variation with temperature of the solubility of W + C, of Mo, of Be, or Cu in Fe offers a variety of precipitation hardening alloys of decreasing order of utility. In addition to C, Cr, N, P and, perhaps, O are causes of temper brittleness. Al lacks allotropic transformation characteristics of Fe and, therefore, the character of solvent undergoes no fundamental change with temperature. Intermetallic compounds such as $CuAl_2$, Ag_2Al, Mg_2Si show a marked change with temperature in the solubility in Al; due to increased dissociation at elevated temperatures, Ni base alloys may be hardened by virtue of change in solubility of certain alloying elements therein. Cu behaves similarly to Ni and Al, being devoid of any useful allotropic transformation. Au base alloys of wide range of composition are likewise amenable to precipitation hardening. Considers also alloys of Zn, Sn base alloys and extruded Pb alloys. VSP (5a)

The Ternary System Iron-Chromium-Nickel (Das Dreistoffsystem Eisen-Chrom-Nickel). F. WEVER & W. JELLINGHAUS. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung,* Vol. 13, No. 6, 1931, Report No. 176, pages 93-108; *Stahl und Eisen,* Vol. 51, May 21, 1931, pages 651-652.

The results of thermal and dilatometric analysis, structural and X-ray investigations were used to establish the ternary diagram. The effect of Cr and Ni upon the polymorphism of Fe is an additive one, i. e., a continuous transition from the system Fe-Cr with its closed γ-field to the system Fe-Ni with its widened γ-field takes place. GN (5a)

Geometrical Relations Among the Structures of Modifications of a Substance (Geometrische Beziehungen unter den Strukturen der Modifikationen einer Substanz). HIKOROKI SHOJI. *Scientific Papers Institute Physical and Chemical Research* No. 328-329, Vol. 16, Oct. 1931, Abstracts, pages 81-83.

Results of investigations of the transformation of crystal lattices. According to the velocity of the transformation, the atomic or molecular groups can be arranged in planes or in helices. A number of elements and compounds with very similar structural relations are enumerated. Ha (5a)

Relationships Among the Iron Alloys (Zur Systematik der Eisenlegierungen). F. WEVER. *Proceedings World Engineering Congress,* Tokyo, 1929, published 1931, Vol. 34, *Mining & Metallurgy,* Part 2, pages 239-250.

From a correlation of the atomic radii, atomic volumes, and crystal structure of the elements, a periodic table is given showing the effect of the element on the gamma field. HWG (5a)

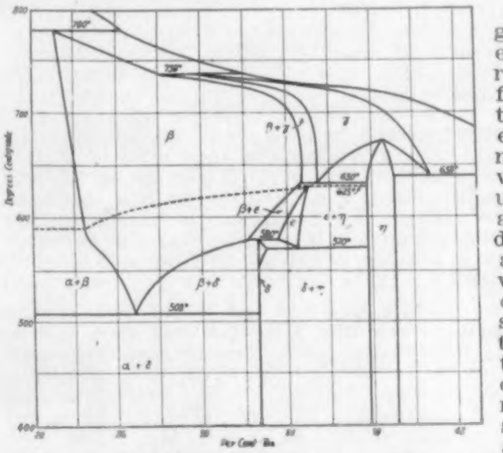
The Binary System Iron-Chromium (Zur Kenntnis des Zweistoffsystems Eisen-Chrom). F. WEVER & W. JELLINGHAUS. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung,* Vol. 13, No. 10, 1931, Report 180, pages 143-147; *Stahl und Eisen,* Vol. 51, July 16, 1931, page 918.

In investigating the microstructure of pure Fe-Cr alloys, only solid solutions were observed just below the freezing temperatures. However, after a heat treatment at 600° C., the alloys with 40-50% Cr showed a new phase which disappears after heating to 1200° C. and quenching. X-ray pictures of this phase show a remarkable accordance with the compound found in the diagram Fe-V (See F. Wever & W. Jellinghaus, Mitteilungen Kaiser Wilhelm Institut, Vol. 12, 1930, pages 317-322). The new phase is supposed to be a compound with 48.22% Cr and possesses a limited solubility in its compounds. The binary diagram is newly established. GN (5a)

Some New Aspects of the Iron-Carbon Diagram. H. A. SCHWARTZ (National Malleable and Steel Castings Co.). *American Society for Steel Treating,* Preprint No. 5, 1931, 27 pages, 27 references.

Paper read and discussed at the Boston Convention of the Society in Sept. 1931. The author discusses the equilibrium diagram as an expression of certain energy relation and not merely a plot of transformation points. The Acm and Agr lines are studied in the light of the solubility equations and the specific heats of Fe, C and cementite. The author presents as conclusions justified by the discussion, (1) graphitization is a phenomenon occurring in as nearly pure binary alloys as are obtainable; (2) if graphitization can occur at a given temperature, it can also occur at any higher temperature where the solid alloy exists; (3) graphitization can occur at 650° C. (1200° F.) but there may be a limiting temperature below which cementite is stable, no data are available for calculating this temperature as it exists; (4) austenite and boydenite are distinct in kind and not identical when of the same C concentration; (5) the thermal data show no evidence of the decomposition of cementite on passing into solution in austenite; (6) reasons exist for not attempting to show without further evidence that solid Fe is monatomic. WLC (5a)

On the Equilibrium Diagram of Copper-Tin Alloys. MATSUJIRO HAMASUMI & SEIJI NISHIGORI, Technology Reports Tohoku Imperial University, Japan, Vol. X, June 1931, pages 131-187.



The equilibrium diagram of Cu-Sn system, especially that of the range of composition from 15-41% Sn, was thoroughly investigated by means of several methods. The liquidus was determined by the usual thermal analysis and the solidus, by the differential thermal analysis. For the investigation of the change in the solid state, the differential thermal analysis, dilatometric measurement, electrical resistance measurement, microscopic examination and the X-ray analysis were applied. The figure shows the diagram obtained by the present investigation. In this region, 4 solid phases, β, γ, δ and η exist, as determined by previous investigators. Besides, a new phase, ϵ was found by the present investigation. The η-phase, consisting of a compound Cu_3Sn, is formed from the γ-phase after solidification; the freezing interval of an alloy with this composition is about 20°. The δ-phase corresponds to a compound $Cu_{13}Sn_8$, as already pointed out by Westgren, but not Cu_4Sn as formerly considered by previous investigators. There occur 8 non-variant reactions, which are shown in the following scheme:—

α+melt β (780°); β+melt γ (738°);
γ η+melt (638°); γ $\beta+\eta$ (630°);
$\beta+\eta$ ϵ (626°); $\beta+\epsilon$ δ (580°);
ϵ $\delta+\eta$ (570°); β $\alpha+\delta$ (508°).

The change observable at 580° in the $\alpha+\beta$ field is due to the rapid change of solubility of the α-phase in the β-phase but not to the allotropic change in the α-phase. The β-phase shows the different structure by quenching, according to the composition; that is, alloys with up to 25% of Sn show an acicular structure; those of 25-28% of Sn are homogeneous; those in which the δ-phase primarily separates on slow cooling show the troostitic structure by quenching; while those in which the ϵ-phase primarily separates on slow cooling is homogeneous by quenching. The field in which β- and γ-phases coexist, is markedly upward convex. The eutectoid structure $\beta+\eta$ to be formed at 630° is observable only by rapid cooling; by slow cooling the β- and ζ-phases grow to large crystal. The new phase, ϵ, exists in the temperature range between 630° and 570°, being formed by the pertectoid reaction, $\beta+\eta\rightarrow\epsilon$, at 625° and decomposes into $\delta+\zeta$ by the eutectoid reaction at 570°, which is readily supercooled to the room temperature. The δ-phase is formed by the peritectoid reaction, $\beta+\epsilon\rightarrow\delta$, at 580° and has no range of solid solution at the room temperature. The η-phase has nearly 1% of the range of solid solution between 37.8-38.9 % of Sn. There is a remelting reaction at 638° on cooling, by which the γ-phase changes to the η-phase and the melt, as pointed out by the previous investigators. See also *Metals & Alloys,* Vol. 2, Nov. 1931, page 249. TM (5a)

The Diffusion of Tin into Iron with Special Reference to the Formation of Columnar Crystals. BANNISTER & W. D. JONES. *Engineer,* Vol. 152, Oct. 2, 1931, page 346.

Abstract of a paper read before the Iron & Steel Institute, Swansea, Sept. 1931. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 302. LFM (5a)

Regeneration of the Recrystallization Ability by Retro-Formation (Rückbildung des Recristallisationvermögens durch Rückformung). P. BECK & M. POLANYI. *Zeitschrift für Elektrochemie,* Vol. 37, Aug.-Sept. 1931, pages 521-524.

The object of this investigation was to discover to what extent the recrystallization which starts by bending a crystal rod can be eliminated by bending it back again and whether, if this takes place, the densification goes back, too, or progresses further (as has heretofore been assumed) even at retrograde recrystallization. The tests were made on Al crystals. The conclusion reached was that it depends on the degree of deformation if a recrystallization occurs under the conditions specified before, but the ability for recrystallization is reduced by retro-forming; the densification is not. Ha (5a)

The Magnetic Properties of Cobalt-Chromium Solid Solutions in Dependence on the Temperature (Die Temperaturabhängigkeit der magnetischen Eigenschaften bei den Kobalt-Chrom-Mischkristallen). F. Wever & H. Lange. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung,* Vol. 12, No. 22, 1930, Report No. 167, pages 353-363; *Stahl und Eisen,* Vol. 51, Feb. 26, 1931, pages 264-265.

The investigation continues the investigation made by F. Wever and U. Haschimoto, *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung,* Vol. 11, 1929, pages 293-330. After describing the apparatus and the method for taking the magnetizing-temperature diagrams of the above-mentioned solid solutions in the concentration range up to 15% Cr, the results are presented and discussed and the former equilibrium diagram is completed. Most remarkable is the large hysteresis of the phase transformation and the parallel course of the magnetic transformations of the α-phase and β-phase. The large hysteresis of the phase transformation is theoretically explained. In accordance with the nature of the β-transformation of pure Fe, the magnetic transformation of the system Co-Cr does not have the properties of a phase transformation. GN (5a)

The Effect of Alloying Elements upon the Polymorphic Transformations of Iron (Ueber den Einfluss von Legierungselementen auf die polymorphen Umwandlungen des Eisens). F. Wever. *Mitteilungen Kaiser Wilhelm Institut für Eisenforchung,* Vol. 13, No. 14, 1931. Report 184, pages 183-186.

The alloying elements of Fe are classified in 2 groups, according to the effect on the polymorphic transformations. In the first group belong those elements which increase the stability of γ-iron and correspondingly shift the transformation towards the α-iron side. The other group comprises those elements which show just the opposite effect from the first mentioned group. Each of these 2 groups may be still further sub-divided, whether or not the solubility is sufficient to form γ-solid solutions without a gap of miscibility or a closed γ-field or whether or not 3 phase equilibria exist among α-solid and γ-solid solutions and a ternary crystal type. It is shown that the behavior of the alloying elements mentioned above cannot be explained by crystallographic relations but a simple relation can be established to the radii of the atoms. GN (5a)

On the Possibility of Grain Growth of Steel below the Pearlitic Transformation (Über die Möglichkeit des Kornwachstums im Stahl unterhalb der Perlitumwandlung). F. Sauerwald & F. Pelka. *Stahl und Eisen,* Vol. 51, Oct. 29, 1931, page 1344.

Cylindrical specimens (diameter, 25 mm.; height 25 mm.) of a steel containing 0.48% C, 0.29% Si, 1.01% Mn, 0.044% P, 0.27% S, 0.13% Cu which is used as a die steel where subjected to a load of 4 kg./mm.^{2} at 600° C. for 12 hrs. in order to determine whether or not slight deformations cause a grain growth. No such effect could be observed. Further experiments with repeated heating and cooling made no change in the structure. Evidently the possibility of crystallization, even after a slight preceding deformation, is very limited below the pearlitic temperature in higher C steels. GN (5a)

Austenite and its Decomposition (L'austénite et sa décomposition). A. Sauveur. *Congrès International des Mines, de la Métallurgie et la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 335-342.

Discussion of dendritic and Widmanstätten structures. Compare article of same title in Transactions American Society for Steel Treating, Vol. 17, February, 1930, pages 199-218.

See *Metals & Alloys,* Vol. 1, Oct. 1930, page 794. HWG (5a)

The Time Law of the De-Strengthening of Deformed Metals (Ueber das Zeitgesetz der Entfestigung verformter Metalle). F. Sauerwald. *Zeitschrift für Elektrochemie,* Vol. 37, Aug.-Sept. 1931, pages 531-534.

The de-strengthening of deformed metals can take place in 2 different ways: (1) crystals in which a strengthening has taken place by plastic deformation can "recover" again thereby reducing the resistance to deformation; (2) new crystals can form which do not show any strengthening (this is the case particularly in a conglomeration of deformed crystallites). The total deformation resistance of a metallic body is also reduced here. The times necessary for recovery and de-strengthening by recrystallization were measured on cylindrical samples of 10 or 15 mm. diameter by measuring the hardness after a definite cold treatment. The curves are reproduced. Ha (5a)

Comment on the Cu-Pb and Similar Heterogeneous Systems (Zur Kenntnis des Systems-Kupfer-Blei, und verwandter heterogener Systeme). W. Claus. *Kolloid-Zeitschrift,* Vol. 57, No. 1, 1931, pages 14-16; *Zeitschrift für Metallkunde,* Vol. 23, Sept. 1931, pages 264-265.

The curve separating the 2 liquid-layer field of the Cu-Pb system from the field for homogeneous melt shows its zenith at 1600° C. when electrical conductivity of the melt is taken as a criterion but, on the basis of holding at temperature for hours and analyzing the top and bottom of the melt, the existence of 2 liquid layers appears to begin only after cooling to about 1000° C. Claus' explanation for this seeming discrepancy is that the 2 phases are present as an emulsion, so that the equilibrium diagram should be drawn with the peak of the curve at 1600° C., to show a 2-phase field, but that this dispersion separates at lower temperatures into 2 actual layers, so the 1000° C. peak represents the agglomeration of the dispersed particles into masses large enough to separate, rather than a true phasial boundary. RFM + HWG (5a)

The "Graphitization Curves" of N. Hekker (Ueber die "Graphitisierungskurven" nach N. Hekker.) A. Merz & H. Schuster. *Giesserei mit Giesserei-Zeitung,* Vol. 18, June 19, 1931, pages 496-499.

The author disagrees with Hekker in believing that equilibrium curves in the Fe-C diagram can be calculated and shows with different examples that the actual conditions do not agree with Hekker's calculations. Ha (5a)

Structure & X-ray Analysis (5b)

The Scattering of X-Rays from Paraffin, Aluminum, Copper and Lead. Allen W. Coven. *Physical Review,* Vol. 38, Oct. 1931, pages 1424-1431.

The radiation from a W-target X-ray tube operated at 80 kv. was filtered through 0.244 cm. Al and the intensities of the scattered radiations from, paraffin, Al, Cu and Pb were observed by the ionization method. The scattered intensities at angles in the range of 30° to 120° with the forward direction of the primary beam were compared with the scattered intensities at 90°. The scattering from paraffin and Al was at an effective wave length of 0.32 A.U.; from Cu 0.26 A.U. and from Pb 0.27 A.U. WAT (5b)

Hexagonal Nickel (Über hexagonales Nickel). G. Bredig & E. Schwarz von Bergkampf (Technische Hochschule Karlsruhe). *Zeitschrift für physikalische Chemie,* Bodenstein Festband, 1931, pages 172-176.

New tests confirmed that a metallic, unmagnetic Ni-deposit of hexagonal atomic arrangement is secured by the cathodic atomization of Ni in an atmosphere of hydrogen. Slight rise in temperature in an H_2-current causes the unmagnetic hexagonal Ni to be converted into the regular magnetic Ni of the cubic lattice. The same phenomenon was observed if N was employed instead of H. The structural arrangement was investigated by X-rays. EF (5b)

X-Ray Investigations in the System Cd-Mg (Roentgenographische Untersuchungen am System Cd-Mg). U. Dehlinger. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 194, Dec. 9, 1930, pages 223-238.

The experiments were made by the method of Debye-Scherrer on alloys containing 30%, 33.3%, 40%, 42%, 55%, 65% and 80% (atomic) Mg after annealing at 300° C. for 4 weeks and subsequent quenching. 2 series of solid solutions exist at this temperature; they are separated from each other by a gap between 30 and 40% Mg. They possess the lattice of hexagonal, densest sphere arrangement of Cd and Mg, respectively, with a ratio of the axes of 1.89 and 1.62 respectively in all tested compositions. 25-65 atomic % of the 2 series of solid solutions are mutually transformed under the influence of the pressure (cold working). $MgCd_3$ and $CdMg_3$ which contain all lines of the spectrum of Cd and Mg in unchanged location and intensity are formed. Additional lines which are due to an ordered atomic distribution are, however, also present. The lattice dimensions have been determined. Ha (5b)

The Rearrangement of a Solid Metallic Phase (Über Umwandlungen von festen Metallphasen). U. Dehlinger & L. Graf. *Zeitschrift für Physik,* Vol. 64, Aug. 28, 1930, pages 359-377.

From X-ray diagrams of a Cu-Au alloy (50 atomic % Cu and 50 atomic % Au), the conclusion is drawn that the transition of the modification consisting of cubic solid solution to the tetragonal system passes through a well characterized intermediate phase of definite lattice constant and tetragonal symmetry, though the atoms are only partly ordered. The electric conductivity is found to go parallel to the structural change. Though the cubic and the tetragonal modification are very soft, the intermediate state is exceedingly hard. The cause for the transition of the cubic phase to the tetragonal intermediate state must be due to the valency electrons. (5b)

Investigation of Gold-Copper Alloys by the Refraction of Rapid Electrons (Untersuchung von Gold-Kupfer-Legierungen mittels Beugung schneller Elektronen). O. Eisenhut & E. Kaupp. *Zeitschrift für Elektrochemie,* Vol. 37, Aug.-Sept. 1931, pages 466-473.

An apparatus for the examination of matter by means of electron refraction and the method used are described. These investigations are possible for practical purposes. The electrons used had a velocity of 20-70 kv., which corresponds to wave lengths of 0.085-0.044 A.U., which is shorter than the X-rays usually applied. The difference between the 2 methods is that the interferences of the refraction of the electron give a picture of the state of the very exterior layers of the metal because they do not penetrate more than a few hundred layers of the atoms, while X-rays penetrate deeper. The application of these electrons on Au-Cu foils shows that the time of the formation of the uniform solid solution depends on the annealing temperature. A tetragonal structure could be proved for a 50% Au-Cu alloy. For a thermal treatment above 400° C. of 50% Au-Cu and also Au-Al, a lattice of the type of zinc blende exists. 10 references. Ha (5b)

Secondary Emission From Nickel by Impact of Metastable Atoms and Positive Ions of Helium. Marshall C. Harrington. *Physical Review,* Vol. 38, Oct. 1931, pages 1312-1320.

Experiments on the secondary electron emission from nickel electrodes due to bombardment by positive ions and metastable atoms in a helium discharge under conditions similar to those obtaining in a glow discharge are reported. The method of measurement is similar to that of Uyterhoeven and Harrington. The proportion of the measured current at the cathode which is carried by electrons is found to be 15 to 50% depending upon experimental conditions. Similarly, the number of electrons per slow positive ion is found to range between about 8 and 20%. The secondary electrons originate at the surface of the collector with about 15 volts maximum initial energy. WAT (5b)

The Structure of Rolled Cadmium (Ueber die Walztextur von Cadmium). E. Schmid & G. Wassermann. *Metallwirtschaft,* Vol. 10, Sept. 18, 1931, pages 735-736.

Contains 3 references. Cadmium sheet 10 mm. thick was cold rolled to 0.05 mm., cooling in water between passes. In spite of cooling, some recrystallization takes place. X-ray patterns were taken at various angles according to the method used previously by the authors for other metals and the results are summarized diagrammatically. The crystal orientation in rolled Cd is very similar to that in rolled Zn. CEM (5b)

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

On a Magnetic Testing Method for Wire Ropes (Über ein magnetisches Verfahren zur Prüfung von Drahtseilen, insbesondere Förderseilen). F. WEVER & A. OTTO. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung,* Vol. 12, No. 24, 1930, Report No. 170, pages 389-390; *Stahl und Eisen,* Vol. 51, Apr. 9, 1931, pages 468-469.

The new magnetic testing method for tubes which was previously described was used to test a wire rope of unknown origin. Disturbances on the magnetization curve of the rope were shown to be due in all cases to cracks of the individual wires. Increased disturbances indicated cracks of 2 wires at the same location of the strand. GN (6)

Riveted and Welded Bridge Tests. *Canadian Engineer,* Vol. 58, June 10, 1930, page 665.

An extended abstract of a paper by R. BERNHARD in the *Zeitschrift Verein deutscher Ingenieure,* Nov. 23, 1929, See "Continuous Tests on Riveted & Welded Bridges," *Metals & Alloys,* Vol. 1, Nov. 1930, page 845. VVK (6)

Wire Rope Testing Machine. *Metallurgia,* Vol. 4, Sept. 1931, pages 139-140.

A description of the million pound capacity vertical machine recently made for the Canadian Department of Mines. The machine can test wire rope specimens of 11 in. circumference and 6 ft. long. JLG (6)

On the Relaxation Times of Some Materials under Dynamic Stress (Ueber die Relaxationszeiten einiger Werkstoffe bei dynamischer Beanspruchung). A. ESAU (University of Jena). *Zeitschrift für technische Physik,* Vol. 12, Sept. 1931, pages 492-495.

A formula of Becker (*Zeitschrift für Physik,* Vol. 33, 1925, page 125) originally developed for the determination of the damping ability of materials was employed to determine experimentally the relaxation time 1/R (R = the material constant) of the following alloys: brass = 1/1 500, Duralumin = 1/750 and Electron-metal: 1/50 —1/100. EF (6)

The Effect of Rate of Bending in Notched-Bar Bending Tests. JAMES GRAY DOCHERTY. *Engineering,* Vol. 131, Mar. 13, 1931, pages 347-350; Mar. 27, 1931, pages 414-415.

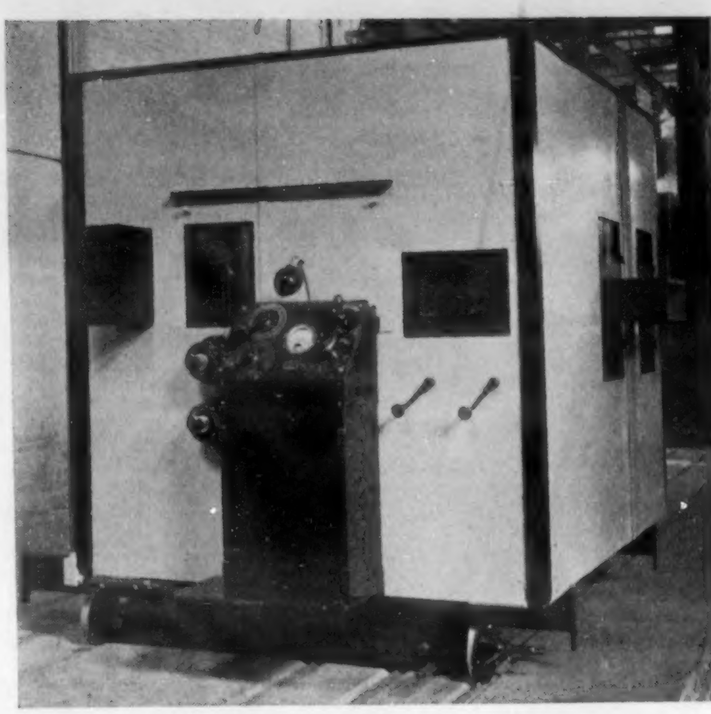
Attempt was made to show the relation between the slow bend and the Izod notched-bar test. Tests were carried out on the following metals: 0.25% C steel as rolled and normalized, normalized 0.35% C steel, normalized 3% Ni steel, Monel metal as rolled and annealed, annealed naval brass, phosphor bronze as rolled and annealed and heat treated Cr-Mo steel. In these tests the maximum rate of travel has been increased from 50 in./min. to 150 in./min. The slowest rate used was 0.05 in./min. Results of the notched-bar bending tests are shown plotted on a logarithmic scale; separate figures are used to show energy, energy absorbed, maximum load, and values of ductility factor. Results of these tests show that for all the ductile metals tested including annealed naval brass; the energy absorbed in bending or in fracture increases with the speed of test. In the case of annealed Monel metal the type of fracture becomes more brittle with slower rates of testing. In actual fracture there is much less plastic flow and much greater opening at the root of the notch. This may indicate that fracture proceeds first by ductile shearing but later in the test, stress concentrations are such that brittle cracking occurs. Annealed Monel metal is not abnormally lacking in toughness at low speeds but is abnormally tough at high speeds. The decrease of load begins much earlier in the test of nickel steel and the rate of decrease is much more rapid in the case of mild steel. The crack once started travels for a considerable distance. This is shown by the audibility of the crack during the test, the appearance of a bright band across the broken face of the specimen, and by the sudden drop of load in the diagram. In the case of nickel steel at the lowest speeds of test, the proportion of specimens which crack is small. The crack is slight showing a narrow bright band and the energy lost due to the slight drop of load is small. The energy absorbed by the uncracked specimens increases with speed and the falling off of the mean of all tests at higher speeds is due to increasing violence of the crack and to the greater number of cracked specimens. Energy absorbed during notched-bar bend tests depends mainly on the maximum load carried during the test and the travel of the striker before the load begins to fall off rapidly. The energy absorbed in each test was divided by this maximum load giving an "equivalent length of diagram." This is large for ductile materials and small for brittle materials. This length may then be called the "ductility factor." In all materials examined, the maximum load increases with speed. The ductility factor increases with the speed only in the case of annealed phosphor bronze and naval brass. Tests were also made to determine the relation between the notched-bar test and the ordinary tensile test. Curves are given showing the results of these tests. LFM (6)

Photoelasticity Assumes Prominent Place in Stress Determination. *Machine Design,* Vol. 3, Nov. 1931, pages 38-39.

The photoelastic method was used to determine the stresses of sheet mill housings and press frames; this resulted in changing the design to a better one of less severe stress concentrations. Several qualities of steel were used in these tests. Ha (6)

The Structure Sensitiveness of Magnetism in Metals. F. E. LOWANCE & F. W. CONSTANT. *Physical Review,* Vol. 38, Oct. 1931, pages 1547-1551.

The magnetic susceptibility of Cu, Ag, Pt and Bi was measured for the annealed state and after various degrees of cold work. The cold work consisted of twisting, stretching and pounding. In every case the cold work decreased the diamagnetism (Cu, Ag, Bi), or increased the paramagnetism (Pt). This probably explains the variation in the measured values of metallic susceptibilities as due to a structure sensitiveness. This is attributed to the increase in the paramagnetic contribution of the partly bound electrons of the metal due to cold work. The electrical conductivity is usually decreased. WAT (6)



G-E x-ray installation at Saginaw Works of Wicks Boiler Co. With this equipment, 34 inches of longitudinal seam are radiographed at each exposure.

Fatigue of Metals & Alloys (6f)

The abstracts appearing under this heading are prepared in coöperation with A.S.T.M. Research Committee on Fatigue of Metals.

The Fatigue of Aircraft Parts. J. B. Johnson. *Aviation*, Vol. 30, Sept. 1931, pages 542-546.

"Under-stressing" is the application of repeated stresses at, or just below, the fatigue limit. It has an effect similar to cold working increasing the tensile strength and fatigue limit and reducing the ductility. The increase is small for heat-treated steels, but in the case of 18% Cr, 8% Ni specimens, previously cold drawn, which had been run for 100,000,000 cycles at the fatigue limit (62,000 lbs./in.^{2}) these were run at 70,000 lbs./in.^{2} for 5,000,000 cycles. A further increase to 72,000 lbs./in.^{2} resulted in failures between 75,000 and 100,000 cycles. The fatigue limit of cast iron has been increased 30% and of Cr-Mo cast steel has been increased 20%. "Over-stressing" is the application of original stresses higher than the fatigue limit. A few experiments indicate that a specimen may be over-stressed for a limited number of repetitions without decreasing the fatigue limit. DTR (6f)

Staybolts. Correspondence from H. L. Miller, Central Alloy Division, Republic Steel Corp. *Metals & Alloys*, Vol. 2, Sept. 1931, pages 109-110.

The writer describes comparative corrosion fatigue tests between wrought iron, and Cu-Mo and Ni alloy staybolt irons. Properties and heat treatments are reported. Superiority of alloy steels over wrought iron is shown. WLC (6f)

Universal Testing Machine for Alternating Fatigue Loads (Universalprüfmaschine für Dauerwechselbelastung). K. Rathke. *Zeitschrift Verein deutscher Ingenieure*, Vol. 75, Oct. 10, 1931, page 1289.

A machine of the Losenhausenwerk, Düsseldorf, for tensile, compression and bending tests is described. The material can also be subjected to a pre-stress of any amount, beside the alternating load. The reading instruments can be arranged apart and remote from the machine. Ha (6f)

Fatigue Strength of Carbon and Alloy Steel Plates as Used for Laminated Springs. R. G. C. Batson & J. Bradley. *Proceedings Institution Mechanical Engineers*, Vol. 120, Feb. 1931, pages 301-332.

Includes discussion. Tests were made to ascertain the effect of grinding away the outer skin of the plate on the limiting range of stress under repeated loadings and to discover if the surface effect of the heat-treated spring plates was due to the heat treatment. The analyses of the steels used are given and the testing methods are described in detail. From the results, it can be stated that the condition of the surface layer was the principal factor in causing the fatigue resistance of complete laminated springs to be considerably below that which would be expected from the known mechanical properties of the material of which they were composed. The thickness of the deleterious layer was found to be small. By machining 1/16 in. from the surface, it was practically completely removed; usually, even 10/1000-15/1000 in. would be sufficient. This surface effect was found to be produced by hardening and tempering. Only slight (if any) improvement was obtained by heat treating the spring plates *after* the thin layer had been machined from the surface of the rolled material. See also *Metals & Alloys*, Vol. 2, Oct. 1931, page 215. Ha (6f)

Fatigue Tests of Weld Metal. R. E. Peterson & C. H. Jennings. *Proceedings American Society for Testing Materials*, Vol. 31, pt. 2, 1931, pages 194-203.

See abstract of preprint. *Metals & Alloys*, Vol. 2, Nov. 1931, page 257. Includes discussion, in which it was brought out that better fatigue results would be expected were coated (fluxed) welding electrodes used instead of bare ones. HWG (6f)

Fatigue Stresses, with Special Reference to the Breakage of Rolls. Frederic Bacon. *Proceedings South Wales Institute of Engineers*, Vol. 47, Part 1, Sept. 15, 1931, pages 374-397.

Discussion of article abstracted in *Metals & Alloys*, Vol. 2, Oct. 1931, page 215. AHE (6f)

The Loading Capacity of Bearings for Cylinder Rolls. (Ueber die Tragfähigkeit von Zylinderrollenlagern.) Robert Mundt. *Maschinenbau*, Vol. 10, May 21, 1931, pages 354-357.

The author indicates how to choose the bearings. The specific load is used as an expression of stress on the loaded surface. The relation between life of the bearing and residual load is calculated and an attempt is made to establish an idea of specific stress. Life of the bearing is reduced in fatigue tests. The choice of a suitable and workable conception of the length of life and the premature failure of the bearing is discussed. Calculations are made from load data obtained from 4 reliable roller-bearing manufacturers. The establishment of the hypothesis used in evaluating the data is necessary. MAB (6f)

Fatigue Tests on the M. A. N. Machine. *Metallurgist*, Mar. 1931, pages 44-45; *Mitteilungen aus den Forschungsanstalten (Gutehoffnungshütte)*, Vol. 1, Sept. 1930, page 8.

A. Junger describes experiments on the M.A.N. machine, investigating the effect on the fatigue strength of the condition of the surface of the material and also to see how welded joints behave under alternating loads. Corrosion fatigue experiments are also described. VVK (6f)

Fatigue and Fatigue Testing. *Metallurgist*, Apr. 25, 1930, page 55; May 30, 1930, pages 75-76.

In discussing the notched-bar repeated impact test (the Krupp test) this article notes that investigations made several years ago at the British National Physical Laboratory by Stanton and others showed that if the energy per blow were high the results of repeated-impact tests on notched specimens arranges metals in the same order of merit as Charpy or Izod test results, while for tests with a small amount of energy per blow, the same order as that indicated by fatigue test results. It may be noted that McAdam's results take this conclusion in a general way. The author concludes that the repeated-impact test does not appear to indicate any special inherent property of a metal different from those determined by other tests. (6f)

ELECTRO-CHEMISTRY (7)

Electroplating (7a)

Analysis vs. Guesswork. Theodore Ross (Chromium Service & Sales Co., Inc.). *Metal Industry*, N. Y., Vol. 28, Mar. 1930, page 126.

High standard of workmanship and intensive economy in production costs is rigidly controlled by chemical analysis. Periodic chemical analysis is required to see that quality of nickel solution has not changed. Ni, Cl, alkalinity and boric acid are important parts of nickel plating solution. VSP (7a)

Chromium Plating Technique. Robert D. Zimmerman (Ingersoll-Rand Co.). *Metal Progress*, Vol. 19, June 1931, pages 54-59, 102.

The author describes solutions used and general technique of chromium plating for resistance to abrasive wear. WLC (7a)

Characteristics of Chromium Plating Baths (La détermination de quelques caractéristiques d'un bain de chromage dur). E. de Winiwarter & J. Orban. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 555-560.

Various baths containing CrO_3, $Cr_2(SO_4)_3$ and $NaHSO_4$ were studied, and the temperatures and current densities at which bright deposits were obtained are plotted. Each bath has a definite range outside of which the deposits were not satisfactory. The center of the area within which good deposits were obtained is around 50° C. and 15 amp./dm.^{2} for a bath of 350 gr. CrO_3/liter, 5 gr. $Cr_2(SO_4)_3$/liter, 4 liters distilled H_2O, and about 55° C, 80 amp/dm.^{2} for one of 350 gr. CrO_3/liter, 5 gr. $Cr_2(SO_4)_3$/liter, 5 liters distilled water, + 60 gr. $NaHSO_4$. Intermediate compositions show intermediate loci of satisfactory deposits. The former bath has greater flexibility as to temperature, the latter as to current density. See also *Metals & Alloys*, Vol. 2, Sept. 1931, page 175. HWG (7a)

The Measurement of pH Value in Aged Electrolytic Bath with Emphasis on the Ni-Bath (Die Messung der Wasserstoffzahl in galvanischen Veredlungsbädern unter besonderer Berücksichtigung der Nickelbäder). M. Willmer. *Oberflächentechnik*, Vol. 8, Jan. 6, 1931, pages 1-2.

Commercial electrometric and colorimetric methods for determining the pH value in aged electro-plating baths are described with emphasis on the Ni-bath. Factors influencing the accuracy of measurement of pH value are cited. The experiments showed that, for commercial purposes, a temperature between 20 and 30° C. is best and quinhydrone electrode shall be used. For the colorimetric determination of pH value, bromcresol green and bromcresol red were found to be most suitable; however, oxidizing salts must be absent. ER (7a)

Colorings on Aluminum (Färbungen auf Aluminium). E. Werner. *Oberflächentechnik*, Vol. 8, Aug. 18, 1931, pages 175-176.

The possibility of successfully electroplating pure Al and cast Al, which is often doubted, is defended. It is, of course, necessary to make the material absolutely free of grease and oxide films. The author recommends that a so-called "connecting bath" consisting of 100 g. stannous chloride, 100 g. stannic sodium and 100 g. zinc sulphate be applied first; at room temperature and 3 volts, this gives a good deposit on which, later, Cu or Ni can be deposited; but the temperature must not be too high. The experiments also showed that, for nickel plating, the electrolyte must contain at least as much salts of Mg as salts of Ni. The causes of the formation of blisters are discussed; this may, very likely, be ascribed to too great heating of the parent material which the hard nickel deposit cannot follow directly. Al alloys with Mg (electron and magnalium) cannot yet be satisfactorily electroplated. The tests are not yet concluded. Ha (7a)

The Stability of Cadmium Cyanide Plating Solutions. S. Wernick. *Preprint, Transactions Electrochemical Society*, Vol. 60, Sept. 1931, pages 117-128.

A study of the Cd bath was made mainly to find a set of conditions under which the anode efficiency would equal to cathode efficiency, or, the anode-to-cathode-efficiency ratio would equal to unity. Experimental results show (1) in the presence of little or no free cyanide, the anode to cathode efficiency ratio changes inversely as the Cd content of the bath; (2) with 30 g./l. Cd, the free cyanide content may vary from 50% to 150% (8.68 to 26 g./l. KCN) without increasing the anode to cathode efficiency ratio; (3) NaOH helps to reduce the ratio in a small degree, it has less effect upon conductivity of the electrolyte; (4) current density has marked effect upon anode to cathode efficiency ratio. High current density up to 4.4 amp./dm.^{2} reduces the ratio but makes deposit dark and coarse-grained; (5) temperature increases directly with the anode to cathode efficiency ratio. Deposit becomes spongy above 35° C.; (6) conductivity of electrolyte increases directly with Cd content, free cyanide content and temperature. Anodes of stainless steel are recommended to replace up to 75% of the Cd anodes in order to reduce the tendency of the electrolyte to increase its Cd content. LCP (7a)

Passive and Dense Nickel Deposits, "Armor-Nickel" (Passive und dichte Nickelniederschläge "Panzernickel"). Carl Schuch. *Oberflächentechnik*, Vol. 8, Oct. 6, 1931, pages 208-209.

Normal Ni deposits are always more or less porous and offer, therefore, no absolute protection against corrosion. A Cr deposit is often applied on top of the Ni to impart a denser coating. The new method obtains density of the Ni deposit by preventing the H from depositing with the Ni. In this manner, a film of Ni with only 1-4 pores/cm.^{2} was obtained as compared with more than 12 in the normal deposit. A microphotograph shows the extremely dense, uniform deposition. The method is developed by the Electrochemical Works of F. Blasberg. The composition of the bath is not disclosed. Ha (7a)

Plating of Aluminum for Protection. H. C. COCKS. *Chemical Age*, London, Vol. 22, May 24, 1930, pages 485-486.
A paper before the Electroplaters and Depositors' Technical Society. See *Metals & Alloys*, Vol. 2, Feb. 1931, page 38.

Difficulties of the Electrodeposition of Chromium. J. W. CUTHBERTSON. *Chemical Age*, London, Vol. 23, Metallurgical Section, Nov. 1, 1930, pages 25-26.
Extracts from a paper before the Electroplaters' and Depositors' Technical Society. The work should be ground and polished, cleaned of grease by alkaline electrolytic cleaning, swilled in 10% sulphuric acid, rinsed in water, scrubbed with fine sand for brass and pumice for steel and again rinsed. After cleaning and before nickeling it should not be touched with the bare hands. The best results in Cr plating are obtained from a solution of chromic acid and chromic sulphate in water. Pb anodes should be used as Fe anodes are attacked by the solution, decrease the throwing power and increase the resistance of the solution. The efficiency of the bath depends on the chromic acid-chromium sulphate ratio which is also affected by the temperature and current density. The temperature should be 40° C. ± 3°, the current density 65 to 85 amps./ft.^{2}. Difficulties in technique are also discussed. See also *Metals & Alloys*, Vol. 2, Feb. 1931, page 38.

Electroplating on Cold-Rolled Steel. GEORGE B. HOGABOOM. *Metal Industry*, N. Y., Vol. 29, Sept. 1931, pages 390-392.
Paper read before American Electroplaters' Society, July 1931, and published in the Monthly Review, August 1931. Includes discussion. See *Metals & Alloys*, Vol. 2, Nov. 1931, page 258.
PRK (7a)

The Control of Acidity and Alkalinity in the Metal Plating Industry. *Metal Cleaning & Finishing*, Vol. 3, Apr. 1931, pages 281-284, 302.
The pH-scale is explained and theoretically discussed. The colorimetric method of measuring the hydrogen ion concentration pH with the comparator set is described and a table giving the pH range and color changes for a number of liquids are added.
Ha (7a)

The Mechanical Properties of Copper Deposits. *Brass World*, Vol. 27, July 1931, pages 153-155.
Addition agents have been found the most effective in improving the mechanical properties of Cu plating. The Brinell hardness range of Cu deposited under widely differing conditions from acid sulphate solutions free from organic matter is narrow; there is also a considerable tendency for the formation of rough and nodular deposits at high current densities. No addition agent has been found that has an appreciable influence in effecting the production of smooth deposits at high current densities and which, at the same time, does not materially increase the hardness of the deposit. Phenol can be used in concentrations up to 10 g./liter, and as a chemical method is available by which its concentration can be controlled it appears eminently suitable for use in acid copper sulphate solutions.
WHB (7a)

The Titration of Free Cyanide in Silver Plating Solutions. *Metal Cleaning & Finishing*, Vol. 3, Feb. 1931, page 104.
With a stock solution of potassium argentocyanide, the titration of the free cyanide of silver nitrate could be carried out without having to remove the carbonate present in silver plating solutions, provided dilution sufficient to take care of any interference due to the carbonate is used.
Ha (7a)

Electro-deposition in Non-Aqueous Solvents. *Metallurgist*, July 1931, pages 100-102.
Recent researches, particularly in America, has directed attention to electrodeposition in non-aqueous solutions. At present there is a mass of uncorrelated and to some extent conflicting data on a number of solvents differing widely in physical and chemical properties. The history, with examples, of metal deposition from non-aqueous solutions is briefly reviewed.
VVK (7a)

The Draft Regulations for Chrome Plating. *Chemical Age*, London, Vol. 23, Aug. 2, 1930, pages 102-103.
The regulations of the Medical Inspectors of Factories in regard to Cr plating were discussed by Dr. S. G. Overton at a meeting of the Electroplaters and Depositors' Technical Society in London. The present regulations require exhaust drafts as near the point of origin as possible, bath facilities, rubber or leather boots, gloves and aprons and medical examination every 14 days. A mixture of 3 parts vaseline and one part lanoline should also be rubbed in the nostrils and on the hands as a preventative both before and after work.

Modern Nickel Plating Technique (Die neuzeitliche Vernickelungstechnik). *Oberflächentechnik*, Vol. 8, July 7, 1931, pages 141-142.
A general discussion of modern tendency to use plating baths for quick and thick deposits of Ni. This is obtained by a high percentage of metal with a low percentage of salt (about 2-3% of the metal content). The reasons for acid and alkaline reactions are discussed and the meaning of the pH value which is determining for the acidity or alkalinity of the bath are also explained. A method to determine the porosity of the Ni deposit by means of a potassium-ferricyanide test is described. Ni anodes should be annealed before use to assure a good solubility.
Ha (7a)

Lead and Lead-Antimony Anodes for Chromium Plating. E. M. BAKER & P. J. MERKUS. *Preprint, Transactions Electrochemical Society*, Vol. 61, Apr. 1932, pages 23-29.
For chromium plating from the chromic acid bath the pure Pb anodes are most resistant to corrosion with continuous operation; Sb-Pb anodes are most resistant with intermittent operation (2 min. on, 1 min. off; or 16 hrs. on, 8 hrs. off). Up to 12.5% Sb in the alloy, the corrosion loss in g./amp.-hr. bears a straight-line relationship with the Sb content of the alloy. For continuous operation, the anodic corrosion increases from 0.0085 g./amp. hr. for pure Pb to 0.0093 g./amp. hr. for 12.5%-SbPb. In intermittent operation, the anodic corrosion decreases from 0.01 g./amp. hr. for pure Pb to 0.0074 g./amp. hr. for 12.5% SbPb. The curves plotted from these results intersect at 5.2% Sb. With other modes of intermittent operation, the longer the idle interval in comparison with working interval, the heavier will be the corrosion on pure Pb anodes, but the faster will this corrosion decrease as the Sb content is increased. The presence of Sb up to 12.5% in the Pb anode does not interfere with equilibrium concentration of trivalent Cr. The bath used by the authors was 2.5 Mol CrO_3, 0.025 Mol H_2SO_4, temperature 45° C., anode current density 10.5 amp./dm.^{2}

Manufacture and Uses of Nickel-Clad Steel Plate. WILLIAM G. HUMPTON, F. P. HUSTON & ROBERT J. MCKAY. *Rolling Mill Journal*, Vol. 5, Feb. 1931, pages 123-124.
Abstract of a paper presented at a meeting of the American Institute of Mining & Metallurgical Engineers, held in New York, week of Feb. 16, 1931. See "Nickel-Clad Steel Plate Work," *Metals & Alloys*, Vol 2, Nov. 1931, page 260.
JN (8)

The Adherence of Zinc Coatings. WILLIAM H. FINKELDEY (Singmaster & Breyer, Consultants). *Metals & Alloys*, Vol. 2, Nov. 1931, pages 266-271.
2 divisions of this problem are adherence of the molten Zn to bare iron or steel and the subsequent adherence of the coating under deformation. With proper care in pickling and fluxing the molten Zn will wet the base readily when it reaches the temperature of the Zn bath. Defects traceable to inadequate adherence of the molten coating material in Sn and other plating operations are not experienced with Zn. The problem of an adherent coating to withstand deformation after application is far from simple in the case of Zn. The structure of the Zn coating is discussed and the bearing of these features on the adherence of the coating is shown. Even contour of the layers of the coating is superior to irregular layers in adherence under bending. Generally light coatings are superior to thick ones. The effect of temperature on the growth of Fe-Zn alloys, rate of cooling, Zn bath composition and composition of the base on the adherence of the coating are discussed. C content of 0.6% in the base is conducive to ductile, adherent coatings. Rephosphorized steels of medium C show good coating characteristics. Cracking of the coating is not necessarily a fault as long as peeling does not occur. Zn apparently offers an electro-chemical protection to iron against corrosion and small discontinuities do not impair this protection. The "galvannealing" process is described in which the fluid Zn is converted into the Fe-Zn alloy and no thin layer of Zn remains to peel from the surface and good adherence is obtained.
WLC (8)

New Lead Coating Process. *Brass World*, Vol. 27, Nov. 1931, page 238.
The "Leadhesion" process is commercially applied by the Gross Engineering Corp., Cleveland, Ohio, and is peculiarly applicable to the wide range of tanks, vacuum and pressure vessels, and moving parts of acid-proofed or brine-proofed machinery, etc. The process offers certain technical refinements over the present lead-coating processes.

Use of Alloy Steel More Diversified. J. D. Knox. *Steel,* Vol. 88, Jan. 1, 1931, pages 252-254.

The automobile builders were the first to use alloy steels in quantity. Now, the petroleum, agricultural, machine tool, chemical, railroad and other industries are important consumers. The use of alloy steel forgings is on the increase in all industries. The chemical and allied industries are using increasing amounts of heat and corrosion resisting alloys of Cr and Ni. These alloys are being widely used also for the interior and exterior decoration of large buildings. Larger amounts of tungsten carbide are being used for tool steels and cutting materials. JN (9)

Development of the Welded Fire Box Heating Boiler in Canada. Clifford W. Morgan. *Canadian Machinery,* Vol. 42, Nov. 12, 1931, pages 38-44.

The introduction of the low pressure welded steel firebox boiler, embodying in later types a simplicity of design which ensures a high standard of durability and low operating costs, marks a new era in heating design and construction. Several new types of welded firebox boilers are described and shown by a number of drawings. WAT (9)

Light Alloy Pistons. H. J. Maybrey. *Automobile Engineer,* Vol. 21, Sept. 1931, pages 351-352.

Lightness, mechanical strength at working temperatures, wearing properties, high thermal conductivity, low coefficient of linear expansion, cheapness must be considered in the selection of material for pistons. This article notes, however, that, beside these physico-chemical considerations, the thermal point of view (that is, transferring the heat from the zone of high temperature as quickly as possible) enters into the satisfactory solution of the problem. The investigations along this line of thought have led to the following points: no interior webbing must be employed to mechanically reinforce a weak crown; skirt and head of piston must be continuous; the material should satisfy a formula developed by the French Academie des Sciences which provides that thermal conductivity/density x coefficient of expansion becomes a maximum. A piston developed along these ideas is described. Ha (9)

The Design of Welded Steel Structures. X. H. A. McCreadie. *Welder,* Vol. 2, Aug. 1931, pages 1-6.

In this last instalment, some special constructions are discussed and ways for their calculation are given; for instance, gantries, and crane girders, stairs, piers, dock gates, steel carriage bodies. Ha (9)

Practice in Steel Construction (La Pratica delle costruzioni metalliche). F. Masi. Ulrico Hoepli Milan, 1921. Paper, 7 x 10 inches, 530 pages. Price 80 L.

The preface states that this has been written to fill a need for a technical handbook on structural engineering in the Italian language.

The metallurgical discussion of structural steel is very brief, and not very informative. It is stated that cast iron contains from 1.5 to 6% C. Acceptance tests are dismissed with very brief quotations from the Italian Standards. Design on the basis of use of the steels of higher elastic strength, such as Nos. 48 and 52, and the Si and Ni steels, is apparently well advanced in Italy.

The standards of the Italian railways forbid punching of structural steel, drilling or sub-punching and reaming being required. The book deals with riveted structures, only about 5 pages being devoted to welding and the use of welded assemblies.

The general principles of the mechanics of structures are given, and very many details of design discussed and shown in sketches, in regard to many types of buildings, bridges, cranes, towers, etc. The civil engineer will find this a very complete treatise, profusely illustrated.

H. W. Gillett (9) -B-

Development of Portable Mooring Masts for Dirigibles. Beran von Linden Lansdowne. *Iron Age,* Vol. 128, July 2, 1931, pages 18-20.

There are 3 types of masts: (1) mobile mast; (2) fixed-stubmast; (3) temporary stubmast. Strength of mast depends on size of airships and maximum wind velocities. Ultimate strength of mast should be greater than that of ship. Factor of safety of 2½-3 is ample. Attempts have been made toward international standardization of mooring mast cups and cones. VSP (9)

Steel Floors (Fussböden aus Stahlblech). *Die Schmelzschweissung,* Vol. 10, June 1931, page 140.

Discussion of the possible advantages and economy in using steel sheets for floors instead of wood and the required dimensions, supports, joints, etc. The costs for a floor of 75 mm. I-beams with 5 mm. steel sheets with fire proofing and a cork cover are given as RM 46 for one square meter. Ha (9)

Steel Metal's Important place in Great Modern Buildings. *Sheet Metal Worker,* Vol. 22, Oct. 16, 1931, pages 588-589.

Illustrations and descriptions of ornamental uses in hotels, etc. Ha (9)

The Application of Gas Welding in Art Craft (Die Anwendung der Gasschweisstechnik im Kunstgewerbe). *Die Schmelzschweissung,* Vol. 9, Oct. 1930, page 230.

Shows 2 examples of decorative art welding with gas flame. Ha (9)

Nickel Steel Boilers for New Canadian Pacific Locomotives. *Boiler Maker,* Vol. 31, Apr. 1931, pages 88-91.

The use of a nickel steel having a minimum tensile strength of 70,000 lbs./in.^{2} led to a 27% saving in weight of the barrel course plates against carbon steel boiler plate. Complete data for the locomotive are given. Ha (9)

Cast Steel or Cast Iron Grate Bars. *Boiler Maker,* Vol. 31, Sept. 1931, page 241.

In the locomotives of the United States, Canada and Mexico, only 6%, or a total of 4100 locomotives, have cast steel grates of different types. The large majority, 84%, use cast iron grates. Ha (9)

Metals to Use for Various Parts of Grinding Machines. *Edgar Allen News,* Vol. 10, Nov. 1931, page 992.

Where Mn steel is used for parts taking heavy wear or exposed to hammering, the hardening and flowing effect of this material under such loads must be taken into account in planning the method of bolting it together. Room for expansion must be allowed. Heat treated chrome steel is the most suitable material for grinding plates in ball mills, for partition diaphragms and end liner plates in tube mills. Ha (9)

Interesting Steel Castings for Mining Use. *Edgar Allen News,* Vol. 10, Oct. 1931, page 977.

One piece is a ladle of 7 tons; 7 ft. 6 ins. external, 5 ft. internal diameter; 6 ft. 11 ins. deep; wall thickness 2.5 ins. The other is a bale of 2.75 tons; 7 ft. 1⅛ ins. diameter at the top, 6 ft. 2 ins. diameter at the bottom; 2 ft. 1½ ins. deep. The material is a C steel of 32/36 tons tensile strength with 15% elongation in 2 ins. Ha (9)

Copper Steel in the Manufacture of Locks, Hinges and Similar Wares (L'Acier au Cuivre dans la Confection des Serrures, Charmieres et Materiél Similaire). *L'Usine,* Vol. 40, Oct. 2, 1931, page 11; *Cuivre et Laiton,* Vol. 4, Aug. 30, 1931, page 387.

The use of copper steel in the manufacture of hardware has increased considerably in France because of its rust-resisting qualities. Ha (9)

Plated *vs* Solid Sheets. *Brass World,* Vol. 27, July 1931, page 159.

Well made plated sheets are more economical to use than solid sheets. Examples of plated sheet applications are illustrated. WHB (9)

Arc Welded House Promises New Market for Steel. *Iron Age,* Vol. 128, July 23, 1931, pages 254-255.

A comparison of wood construction with welded steel construction (sills, studs and headers) showed $6720.00 for wood against $6744.00 for steel. The houses have a brick veneer. Ha (9)

Delicate Foods Protected by Lead or Lead-Tin Foil. *Brass World,* Vol. 27, Oct. 1931, page 221.

Pb-foil is used for the protection of tea-leaves against air and sunlight. Pb-Sn foil is produced by rolling a slab of Pb and a slab of Sn in juxtaposition and the 2 gradually reduced to foil, maybe as thin as 0.001 in. This foil is used where the foodstuff cannot be allowed to come in contact with Pb. WHB (9)

Compares Tungsten and Tantalum-Carbide Cutting Tools. *Iron Age,* Vol. 128, Oct. 29, 1931, page 1113.

A brief discussion of the usefulness of this product in other fields of the steel industry, although it is not made in large quantities itself. Ha (9)

British Aluminium Co., Ltd. *Metal Industry,* London, Vol. 38, Apr. 10, 1931, page 378.

A recent development is the use of aluminum alloy pistons in large Diesel engines. The electrical and building industries consume considerable aluminum. PRK (9)

The Making of Mirrors by the Deposition of Metal on Glass. *Bureau of Standards Circular* No. 389, 1931, 17 pages.

This circular has been prepared in response to numerous requests for instruction concerning the preparation of mirrors. The directions are very explicit and are based on the experience of the Bureau over a number of years. The account of the chemical deposition of silver on glass is dealt with in considerable detail, but the methods are also given for the production of reflecting films on glass by the chemical deposition of copper, gold, platinum, and lead sulphide, by cathode sputtering and by the condensation of vaporized metals. WAT (9)

Reading Builds 20 Steel Cabooses. *Railway Age,* Vol. 91, Aug. 8, 1931, page 203.

20 caboose cars are now under construction by the Reading at its Reading, Pa., car shops. The new cars are of all steel construction, equipped with a one piece cast steel underframe, overall length 33 ft. 10 in. Berths and lockers are arranged under the lookout compartment for 6 persons. WAT (9)

Ultra-Violet Reflecting Power of Hyb-Lum. Notes from the U. S. Bureau of Standards. *Journal Franklin Institute,* Vol. 211, Jan. 1931, page 116.

Brief note on "Hyb-Lum," alloy of Al, containing about 2% alloying elements, chiefly Ni and Cr group metals. It is used in therapeutic lamp reflectors. DTR (9)

Truck Tanks of Aluminum Eliminate Scale and Increase Pay-Load 24 Per Cent. *Automotive Industries,* Vol. 64, Apr. 1931, page 551.

Light metal can be safely used for truck tanks for transporting gasoline. In addition to tank, underframe is made of Al structural shapes. A 1400 gal. Al tank weighs 1200 lbs., and capacity load weighs 8680 lbs. Similar steel tank capacity would be 1200 gal. The extra cost of the Al tank ($1000) is made up due to transportation of less dead weight in 2/3 year. Also, it does not scale on the inside of tank, and gasoline will be kept cleaner; by giving the outside of tank a coating of clear lacquer, less heat is absorbed and thus the loss through evaporation cut down. DTR (9)

Use of Duralumin in Strut Attachment to an Upper Wing. *Aviation,* Vol. 30, Sept. 1931, page 555.

A number of interesting constructional features are noted in the attachment of the outer bay struts to the upper wing panel of the new Consolidated Model 21-A Trainer, built by the Consolidated Aircraft Corp. The ribs are formed of heat-treated duralumin. The chord members, both top and bottom, are of a modified channel cross-section with wide, turned back flanges. The web members are straight rolled channels and are assembled to the chord members by riveting with duralumin rivets. Short spacer tubes are used around the rivets to prevent crushing the channels. Completed ribs are assembled by sliding over the spars and are held in place by nailing directly into the wood. DTR (9)

HEAT TREATMENT (10)

Annealing (10b)

Electrically Heated Annealing Furnaces for the Steel and Other Industries. J. C. WOODSON (Westinghouse Elec. & Mfg. Co.). *Iron & Steel Engineer,* Vol. 8, Mar. 1931, pages 122-128; *American Metal Market,* Apr. 3, 1931, pages 3, 5; *Heat Treating & Forging,* Vol. 17, Mar. 1931, pages 285-288, 291.

Paper read at Convention of American Institute of Electrical Engineers, March 1931. Thorough applications of electric annealing furnaces in ferrous and non-ferrous industries. DTR+WHB+Ha (10b)

The Annealing of Steel (Beitrag zur Untersuchung über das Entharten von Stahlen). P. CHEVENARD. *Metallbörse,* Vol. 20, Aug. 16, 1930, page 1828.

The hardening of steel was investigated by means of photomicrographic magnetic and dilatometric methods. Dilatometric curves were determined for the thermic cycles of growth with gradually increasing temperatures and also for the phenomena of isothermic growth under exact determination of the change of length as a function of the time. A special dilatometer with movable photographic plates was used. Constant temperature was insured by special construction. The investigations were made on austenite, the only constituent that can be obtained in a pure state. It was investigated in the state of complete super-hardening. A mixture of austenite-martensite was investigated in a partially superhardened condition and the greatest hardness obtainable was determined in a quenched steel containing the maximum amount of martensite. The phenomena can be explained by the equilibrium diagram but they are complicated by the simultaneous occurrence of the various reactions. The author could eliminate the influence of the simultaneous reactions which had caused the variations of results before. Austenite can lead to the formation of cementite, a reaction which causes contraction, or a mixture of Fe and cementite may be formed under expansion. The formation of martensite, which follows that of austenite, is connected with a contraction that grows with the temperature. In quenched steels there is always a simultaneousness of these 2 phenomena, causing in certain sections of the expansion curve either an arrest in the contraction, a rise, or a slowing down. A direct transition of austenite into martensite during heating could never be observed. This secondary reaction in hardening always occurs in the second period of cooling. This simultaneousness of the phenomena in martensite and austenite can also be observed by means of the electric conductivity. WHB (10b)

Effects of Annealing on Chains. *Heat Treating & Forging,* Vol. 17, Apr. 1931, pages 360-364; May 1931, pages 468-472; June 1931, pages 582-585, 588.

Electric Carburizing Saves Labor of Eighteen Men. E. F. DAVIS (Warner Gear Co.). *Electrical World,* Vol. 98, Nov. 7, 1931, pages 827-828.

An abstract. The major saving of continuous annealing is in faster machining speeds and feeds, lower tool expense, the reduction of rejects due to noisy gears and the general improvement in production conditions. The continuous furnace is not for the small job shop. Furnace development is needed to eliminate roughing operations. WHB (10c)

What the Heat Treater Should Know about Nitriding of Steel. GEO. M. ENOS. *Fuels & Furnaces,* Vol. 9, Jan. 1931, pages 71-80.

The most practical advantage of nitrided steels is their extreme wear resistance. A brief history of the development is given; the nitriding process is explained; the equipment required for nitriding and the steels suitable for this process, the control of the process, testing for hardness and the physical properties of nitrided steels before and after nitriding, the Fe-N system and practical results are discussed and described. Ha (10c)

Carburizing Steels—Benefits Conferred by Alloying Metal. *Iron & Steel of Canada,* Vol. 14, May 1931, pages 87-88.

A discussion, republished from Vancoram Review, of the various types of carburizing steels which have been developed, with particular reference to the Mn-V steels in this connection. OWE (10c)

Gas Carburizing Apparatus. *Journal Franklin Institute,* Vol. 211, Mar. 1931, pages 367-371.

Abstract of *Franklin Institute Report* No. 2893, Oct. 1928. Low carbon steel carburized at 1500-2000° F., in contact with illuminating gas or solid charcoal. The exposed surfaces of the steel absorb about 1% of C to a depth of 1/64 to 1/16 in.; the core or middle portion retaining the original lower percentage of C. The parts are suddenly quenched and acquire a hard case or skin fit to resist wear and a tough core to withstand shock and give the necessary strength. Sketches show Machlet's improved carburizing apparatus. DTR (10c)

An Appraisal of Nitriding. M. A. GROSSMAN. *American Machinist,* Vol. 74, June 18, 1931, page 955.

Review. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 264. Ha (10c)

The Value of Nitriding. *Metallurgia,* Vol. 4, Aug. 1931, pages 123-124.

A general discussion of the method and its application. JLG (10c)

Nitriding Becomes Accepted Heat Treating Method. *Steel,* Vol. 88, Jan. 1, 1931, pages 282-283, 294.

Nitriding is now established as a low temperature hardening process and is being employed on larger castings and on greater quantities of steel. Cost reductions have been accomplished by the use and development of continuous and semi-continuous nitriding furnaces. The problem of containers has been brought close to solution by the development of enameled nitriding pots. A malleable cast iron has been developed which can be successfully nitrided. Short-time nitriding of common steels has been utilized for preventing corrosion. Improvements are seen in methods of sealing furnaces, in quenching systems, and in the greater use of gas-fired furnaces. The use of nitrided alloy tool steels and of nitrided steels in general is increasing. JN (10c)

Nitriding of Iron and Iron Alloys. W. EILENDER & O. MEYER. *Iron Age,* Vol. 128, July 23, 1931, page 255.

Abstract translation of an article in *Stahl und Eisen,* Jan. 29, 1931. Discusses the effects of nitriding on the surface hardness and the structure of Fe and its alloys with C, Al, Cr, Mo and V. See also *Metals & Alloys,* Vol. 2, Sept. 1931, page 177. VSP (10c)

Present Position of Nitralloy in Industry. M. A. GROSSMAN (Illinois Steel Co.). *Metals & Alloys,* Vol. 2, Sept. 1931, pages 150-154.

A paper read before the Washington-Baltimore Chapter, A. S. S. T. The author discusses the manufacture and treatment of nitralloy and the advantages of its use. The disappointments with it are recounted. The economics of the alloy and process are discussed. The paper deals with only one nitralloy, Cr 1.50%, Mo 0.20%, and Al 0.70% with varying C content. WLC (10c)

The Influence of Metallic Coatings on the Mechanical Properties of Steel in Nitriding (Der Einfluss metallischer Ueberzüge auf die mechanischen Eigenschaften von Stahl beim Nitrieren). TADAMASA YOSIKI. *Scientific Papers of the Institute of Physical and Chemical Research,* Tokyo, No. 292, 1931, pages 143-154.

The tests were made on a steel of 0.3% C which, after annealing, was nitrided at 650° C. by disintegration of ammonia gas from 10 min. to 1½ hrs. The tensile strength increased with time; elongation was reduced at first, then remained constant. After tinning, the same sample was again treated in the same manner; both tensile strength and elongation showed a diminution. Coating with different metals again showed that nitriding cannot be done with as good results as in the sample which is not covered. A chromium-nickel steel showed the same behavior under impact tests: the nitrided surface was removed by tinning and the improved properties decreased. From the results, it can be concluded that the very thin layer of iron nitride formed during nitriding greatly influences the mechanical properties of steel. 12 references are cited and a plate of micrograph illustrate some of the tests; the numerical data for them are given in tables. Ha (10c)

Carbonal Hardening. GEO. TURNER. *Automobile Engineer,* Vol. 21, Sept. 1931, pages 353-354.

Description of an electric resistance carburizing furnace for routine operation. Ha (10c)

A Practical Method of Obtaining the Depth of Carburized Case. J. SORENSON. *Fuels & Furnaces,* Vol. 9, Mar. 1931, pages 329-331.

The Brinell hardness test was used for determining the depth of the case. Tables show the values for carburized steels in 1/32 in., 3/64 in. and 1/16 in. depth. Ha (10c)

Energizing Action of Various Chemicals in the Carburization of Steel with Solid Carburizing Agents. R. A. RAGATZ & O. L. KOWALKE (Univ. of Wisconsin). *Metals & Alloys,* Vol. 2, Nov. 1931, pages 290-296.

5 references. Current theories of the action of energizers in carburizing are discussed. Compounds of the 8 groups of the periodic system were studied under described conditions. The energizing effect is not dependent upon the evolution of CO_2, but is a function of the properties of the metallic oxide portion of the energizer. Compounds such as calcium and magnesium carbonates which evolve considerable CO_2 are inert, while materials without evolution of CO_2 have marked energizing effects. Compounds of Cr, Mo, W, Mn, Fe, Ni and Co without the presence of any alkali or alkaline earth metals act as energizers. The inhibiting actions Sn, Bi, Sb and Pb are discussed. Carbonates of Na and Ba are the cheapest and strongest energizers. WLC (10c)

Malleableizing (10g)

Accelerated Annealing of Malleable Cast Iron. (Recint accéléré de la fonte malléable.) V. V. OUSSOV & N. N. POUSTYMYKOV. *Vestnik Metallopromychl,* Vol. 10, June 1930, pages 97-103; *Chimie & Industrie,* Vol. 25, Feb. 1931, page 352.

The American process is too long, requiring 100-120 hrs. The General Electric Company has succeeded in reducing the time required to 28-30 hrs., but this requires the use of electrical furnace. The authors have endeavored to render the process suitable for application in ordinary case hardening furnaces. Their work has shown that (1) in order to accelerate graphitization of the free cementite, it is merely necessary to keep the iron above 1000° for 2 hrs., at the end of which time the metal consists exclusively of the solid solution and of graphite; (2) to reduce the time required for graphitization of the cementite which separates on cooling, the metal must be cooled rapidly to 710° and maintained 4 hrs. at this temperature to decompose the pearlite formed by cooling into ferrite and graphite. This process required only 8-10 hrs. in the laboratory and 16 hrs. in a petroleum-heated muffle furnace. WHB (10g)

JOINING OF METALS & ALLOYS (11)

Welding & Cutting (11c)

The Weldability of Carbon Steels. (Ueber die Schweissbarkeit der Kohlenstoff-Stähle.) D. Seferian. *Schmelzschweissung,* Vol. 10, Nov. 1931, page 263; *Revue de la Soudure Autogene,* Vol. 22, No. 201, pages 2135-2140.

For the identification of steels from the metallurgical point of view, Grandon has developed a general formula for a welding coefficient which states that the weldability of ordinary steels is inversely proportionate to the C content. The following table is given:

Carbon content	Kind of steel	Welding coefficient	Weldability
up to 0.25%	very soft and soft	1-0.9	excellent
0.25-0.50%	semi-soft and semi-hard	0.6-0.5	moderate
0.50-0.80%	hard and very hard	0.3-0.1	not weldable

This factor can be used in the formula of Lame for the calculation of the thickness of welded tanks: $T = a\ Pd/2e$, where T is the safety factor of the steel, P the pressure to which the tank is subjected, d the diameter, e the wall thickness and a the welding coefficient of the table. The formula has, in many instances, been found to be satisfactory, but it is especially mentioned that it is applicable only with the welding methods and materials of our present knowledge. Probably, further developments in methods and in the flame of welding torches may tend to increase the welding coefficient. Ha (11c)

Butt-Welding Joints Having a Cross-Section of Eighteen Square Inches. M. Thomson. *Machinery,* Vol. 37, July 1931, pages 833-834.

The heated faces of motor frame rings are heated and forced together under a suddenly applied hydraulic pressure of 100,000 lbs., thus insuring a homogeneous weld. Ha (11c)

The Application of Welding to Armament. John W. Slattery & W. W. Ransom. *Army Ordnance,* Vol. 12, Nov.-Dec. 1931, pages 202-205.

Description of examples of repairing or reinforcing corroded or overstressed parts of ordnance by electric cutting and welding. The equipment of the Rock Island Arsenal is described. Ha (11c)

Oxwelding in Plant Maintenance. *Oxy-Acetylene Tips,* Vol. 9, Dec. 1930, pages 91-96.

The importance of a central welding department to plant operation is pointed out and illustrated by examples of automobile factories, oil refineries, refrigeration, foundries and steel plants, electric railways, etc. Welding should be organized on the same basis as other industrial plant maintenance activities. Ha (11c)

Ocean Outfall Oxwelded. *Oxy-Acetylene Tips,* Vol. 9, Dec. 1930, pages 86-87.

Description of welding and installing a wrought-iron pipe line for sewage disposal in the ocean. Ha (11c)

Welding Sequence Highly Important in Structural Members. *Electrical World,* Vol. 98, July 11, 1931, page 68.

The new Southern California Edison building in Los Angeles, Cal., was designed to be earthquake-proof and, therefore, was designed for horizontal forces as well as vertical loads. Floor beams were riveted and then electrically welded to the vertical H column so that full beam strength would be developed in the floor members. Electric welding was employed because of saving in material and the more compact detail of the welded connections. WHB (11c)

Cutting Risers with Oxy-Acetylene. *Metallurgia,* Vol. 4, July 1931, pages 91-92.

Runners, risers and fins can be economically cut from steel castings by means of the oxy-acetylene torch. This method of cutting is applicable to both large and small castings. Large castings should be heated before cutting and should be annealed after cutting. The blowpipes should be chosen with care. JLG (11c)

Electric Railways Use Oxy-Acetylene Welding. *Oxy-Acetylene Tips,* Vol. 10, July 1931, pages 115-119.

Illustrates several uses in power plant and rolling stock repair and maintenance which offered great savings. Ha (11c)

Strength of Welded Joints. *Aviation,* Vol. 30, Jan. 1931, page 63.

Abstracted from *N. A. C. Technical Report* No. 348. Gives information on strength, weight, and cost of types of welded joints. DTR (11c)

Bronze Welding Worn Overhead Frogs. *Electric Traction,* Vol. 27, June 1931, page 296.

A brief note on the results of service tests made by the Toronto Transportation Commission on the welding of worn overhead trolley frogs. It has been proved that worn parts built up with bronze, using an oxyacetylene blow-pipe instead of an electric arc will wear as long as new parts, and parts so built-up are readily ground. Parts electrically welded were ground with great difficulty and failed quickly in service. WAT (11c)

Fabrication Processes are Applied in New Fields. *Steel,* Vol. 88, Jan. 1, 1931, pages 280-281, 360.

New uses for electric and oxy-acetylene welding are seen in the manufacture of heavy-walled pressure vessels, in the joining of corrosion-resisting steels and in the construction of long-distance pipe lines. Electric resistance welding machines have been designed to join lengths of pipe in the shop and promise to become a factor in fabricated steel construction. Fusion welding has been applied to structural steel work and to the construction of pressure vessels. More cities are permitting the use of welded building construction. Progress has been made in the X-ray examination and other tests of welded joints. The use of riveting has also advanced. New applications of riveting are found in the fabricating of large traveling cranes made of Al and in all-metal dirigible construction. JN (11c)

The Welding of Saws. *Welding News,* Vol. 2, July 1931, pages 22-23.

Description of some cases of repairing big hand saws. Ha (11c)

The Autogenous Cutting of Structural Steels and Alloyed Steels. (Ueber das autogene Schneiden von Baustählen und legierten Stählen.) From the Research Laboratory of the Autogene-Works, I. G. Farbenindustrie A.-G. Frankfurt a. M. *Autogene Metallbearbeitung,* Vol. 23, May 15, 1930, pages 150-157; June 1, 1930, pages 166-173; June 15, 1930, pages 182-191; July 1, 1930, pages 205-210.

In cutting steel with a flame, the heat of the steel causes changes in the structure near the cut. 3 zones can usually be distinguished: an outer zone in which separation or accumulation occurs combined with a coarsening of the grain; an intermediate zone with a typical refined structure of a very uniform distribution of the C in the steel and fine grain; in the third zone, a transition to the structure of the material takes place. A great number of different steels have been tested and examined with regard to these changes and the physical-technical properties of the autogenous cuts. They are all described in detail and illustrated by micrographs, diagrams and tables. In conclusion, it is stated that autogenous cutting methods should be judged from 2 points of view: (1) the change of structure in the zones near the cut; (2) the appearance and the form respective of the cut. From the tests, no necessity could be found for structural steels up to 150 mm. to machine the cut afterwards on account of the change of structure. Autogenous cutting, in contrast to other machining methods, does not involve any forcible separation of the metal; the heat acts rather as a reinforcement which can be compared with surface hardening in a bath. Machining of the cut may sometimes lead to a deterioration of the material. Of still greater importance than the change of structure is the form and appearance of the cut. Autogenous cutting can be permitted without any objection if the surface is made smooth and straight. This appearance makes it possible to recognize immediately if cutting velocity and flame are properly adjusted and if segregations have taken place. 29 references supplement the paper. Ha (11c)

Recent Experience and Advance in the Utilization of Wheel-Set Built-Up Welding. (Neue Erkenntnisse und Fortschritte bei der Anwendung der Radsatz-Auftragsschweissung.) S. Sandelowsky. *Glasers Annalen,* Vol. 108, April 15, 1931, pages 149-154.

The paper takes the following steps: economy of the wheel-set built-up welding; strength and metallurgical properties; analyses of welding rods and material to be welded; influence exerted by carbon and by the speed of cooling down; pre-welding and welding voltages; significance of water cooling; economy of the welding of wheel axles. 10 illustrations. EF (11c)

Welding of Piping in New York Hospital—Cornell Medical Clinic. C. J. Thale. *Journal of the American Welding Society,* Vol. 10, Oct. 1931, pages 43-44.

Paper presented at the Fall Meeting of the American Welding Society in Boston, Sept. 1931. A brief review of procedure used on a large welding installation consisting of approximately 40,000 diameter ins. of welding. The types of piping welded were: high pressure steam piping for 200 lb. steam; medium pressure steam, 30 to 200 lbs.; low pressure steam, 5 lbs.; hot water heating piping; brine piping. Oxy-acetylene welding was employed; all the welding was done on the job. TEJ (11c)

Developments in Oxy-Acetylene Welding in Aircraft Industry. J. B. Johnson. *Western Machinery World,* Vol. 22, Oct. 1931, pages 451-453.

The past year has witnessed a great expansion in the aircraft industry. Several new factories have begun operations and many of the established factories have increased production. It is noticeable that oxy-acetylene welding has been adopted almost universally. The principal reason for the preference of oxy-acetylene welding over other methods is its adaptability to the welding of thin sections. The weld metal built up with a blow torch forms a smooth fillet and tapers off gradually into the base metal. This is not always true of weld metal deposited by other methods. In order to facilitate production some of the factories have installed acetylene generators and are piping acetylene and O to convenient locations in the plant. WAT (11c)

Patterson Steel Company Makes Employees Welding-Minded. J. A. Montgomery. *Welding,* Vol. 2, Oct. 1931, pages 676-678, 681.

These fabricators and erectors of structural steel taught the principles of arc welding to their employees. TEJ (11c)

American Experiences with Arc Welding (Amerikanische Erfahrungen auf dem Gebiete des Lichtbogenschweissens). *Die Schmelzschweissung,* Vol. 9, Mar. 1930, pages 58-61.

Description of some particular welds in marine practice and their tests. A large storage battery switch in a power station is also described and illustrations of some of the details of construction are included. Great economies in time and cost can be effected by welding bars and profiles instead of bolting them together. Tests with butt-welded plates of 6.3 mm. thickness showed the same good properties as welds with bevel. The first method was, therefore, admitted. Ha (11c)

In the Steel Plant; Oxygen Lance Cutting, a Routine Operation in the Production of Steel. *Oxy-Acetylene Tips,* Vol. 9, Dec. 1930, pages 83-85.

The oxygen lance method of tapping open hearth furnaces is economical and simple. One workman handles the lance while a second adjusts the pressure from a regulator on the drop line. The end of the lance is first put into the furnace until it is red hot. Then the oxygen is turned on gradually and the lance is placed against the plug in the tap hole and the oxygen pressure is gradually increased. In about one minute the plug is pierced. The use of the lance for removing hot tips from ingots is also described. It has also helped to save waste in reclaiming accumulated spills. Ha (11c)

Welding Practice on the Illinois Central System. *Boiler Maker,* Vol. 31, Jan. 1931, pages 9-12.

Instructions to welders and materials used and the current applied in arc welding are outlined. Ha (11c)

Report of Structural Steel Welding Committee. *Journal American Welding Society,* Vol. 10, Oct. 1931, pages 25-42.

First installment of a report by the Structural Steel Welding Committee of the American Bureau of Welding. The results of an investigation extending over a period of years which had for its principal object the determination of stresses that may be safely used in the designing of welded steel structures fabricated under ordinary commercial fabricating shop conditions. 2 sections of the report are included in this installment, consisting of an introduction and procedure followed in the tests. TEJ (11c)

Welding Standards. *Metallurgist,* Jan. 1931, pages 1-2.

The author questions the advisability of the comparatively recent movement to standardize welding. The movement has proceeded further in America than in England but he doubts if anyone is satisfied with the result achieved. "A number of non-destructive tests have been put forward—X-ray examination, electrical, magnetic and acoustical methods have all been proposed and tried with various degrees of success—but none of them as yet appear to have attained a status which would commend them to a British standardizing committee. Only the destructive tests remain, including a tensile or bending test on samples cut from a weld, and the examination of sections cut from the joint." Such testing is expensive in addition to producing a patchwork job that an engineer would hesitate to accept. "In many industries where testing technique is not yet fully developed, business is conducted on a basis of confidence between manufacturer and user. Many goods, even of an engineering character, are bought on the basis of the reputation of the manufacturer and the experience of the user without any rigid specification and with very little testing. While this method is difficult to apply or to maintain under modern conditions, there may still be a case for it as a basis for dealing with such a process as welding." VVK (11c)

The Autogenous Welding of Monel Metal. *Welding News,* Vol. 2, July 1931, page 21.

The essential points to be observed in the process are: size of blow pipe (75 litres acetylene/hr., maximum/ mm. thickness to be welded); perfect regulation of the flame with excess of neither acetylene nor O; use of a special cleansing flux applied to the filling rod and to the reverse of the edges to be welded. More or less rigid clamping of the edges according to thickness in order to reduce the effects of expansion and contraction as much as possible. A few suggestions to the beginner are given. In some cases, Ag brazing is preferable to welding because of the low temperature utilized, its mechanical properties and its resistance to oxidation. Ha (11c)

The Welding of Alloys; Oxy-Acetylene Process Adaptable to Ferrous and Non-Ferrous Metals. *Welding News,* Vol. 2, July 1931, pages 17-19.

The particular methods, precautions, flame adjustments, etc. are described for chrome and chrome-nickel steels, Mn steels, Mo, V and Si-Mn-Cr steels, Si irons, Al and its alloys, Ni and Monel metal, and Cu and its alloys. Ha (11c)

Dictionary of Welding Terms—English, German, Russian. (Fachausdrücke der Schweisstechnik—Deutsch, Englisch, Russisch.) Compiled by the Verein deutscher Ingenieure. VDI—Verlag, Berlin, 1931. Paper, 31 pages. Price 2 RM.

Welding engineers who want to keep informed about the development of their art must study not only the welding literature of their own country but that of foreign countries as well, but this is frequently very difficult because the standard technical dictionaries do not include welding terms which have come into use in the last few years. In order to remedy this condition the welding committee of the Verein deutscher Ingenieure has compiled a welding dictionary including Russian, German and English terms. It is intended to supplement the technical dictionary.
M. L. Moorman (11c) -B-

Repairing All-Metal Railway Coaches by Welding. A. J. T. Eyles. *Engineer,* Vol. 152, Aug. 14, 1931, page 168.

For permanent repairing of aluminum-paneled railway coaches, oxy-acetylene welding is recommended. Special technique and careful manipulation are required. Aluminum flux is used in the form of varnish on the welding rod. To secure homogeneity the welding rod used should be of pure Al. After welding, the weld joint and surrounding metal must be thoroughly cleaned to prevent corrosion. LFM (11c)

U. S. Navy Steps Out With Welded Boilers. *Power,* Vol. 73, May 12, 1931, pages 734-735.

To date the U. S. Navy has ordered 38 boilers with all welded drums. Detailed specifications for these boilers are described. They follow closely the A. S. M. E. code specifications published in the March 1930 issue of *Mechanical Engineering.* VVK (11c)

The Welding Processes. C. A. Adams. *Industry & Welding,* Vol. 2, Oct. 1931, pages 14-16.

The question today is not one of the process by which a weld is made but of its compliance with the engineering and economic requirements for the product welded. The use and particulars of gas flames, design and preparation of work, preheating, brazing and bronze welding are briefly discussed. Ha (11c)

Committee on Welded Rail Joints. Progress Report No. 7, May 1931. *Journal American Welding Society,* Vol. 10, Aug. 1931, pages 14-43.

A progress report of a joint committee of the American Railway Association and the American Bureau of Welding which was organized in 1931 to investigate the various types of welded rail joints in commercial use. The report includes a study of the heat effects of thermit welds on the adjacent rail material; the effect of preheating and postheating welded rail joints; repeated impact tests of joints; a study of butt joints and fish plate joints made with the atomic hydrogen process. The report also includes a study of stresses and distortion due to the heat of welding of low C to high C plates, by Professor T. R. Lawson (Rensselaer Polytechnic Institute). TEJ (11c)

How to Weld the Chromium-Nickel Steels. Part 2. S. Craig Alexander. *Welding,* Vol. 2, Oct. 1931, pages 684-687, 692.

Author gives details of oxy-acetylene and arc welding procedure for austenitic Cr-Ni steels. Expansion and contraction problems are pointed out and remedies suggested. Procedure is given for the welding of "18 and 8" to mild steel and galvanized steel. Directions are given for cleaning, grinding and buffing welds. TEJ+Ha (11c)

Resistance Welding Data. W. Anderson & Malcolm Clark. *Welding News,* Vol. 2, Oct. 1931, pages 28-29.

The 3 types of resistance welding are butt welding, spot welding and projection welding. They are described and the power consumption, size of transformers and speed of operation are given. Ha (11c)

Arc-Welding Large Cast-Iron Pots. Ernest Bauer. *Industry & Welding,* Vol. 2, Oct. 1931, pages 20-23.

Describes some repairs made by welding of cracks in 3 in. welds, thus salvaging expensive pots. Ha (11c)

Electrically Welded Stainless Tubing. J. S. Adelson (Steel and Tubes Inc.). *Welding,* Vol. 2, 1931, pages 689-692.

The author discusses the physical properties of resistance welded "18 and 8" tubing, a recent development. TEJ (11c)

Building Up Welding Fittings on the Job. F. S. Durham. *Welding News,* Vol. 2, Oct. 1931, page 25.

A brief description of welding pipe and fittings on the job. Ha (11c)

Use of Welding in the Fabrication of Stampings. A. F. Davis (Lincoln Electric Co.). *Metal Stampings,* Vol. 4, Apr. 1931, pages 347-350.

Deals especially with the use of arc welding for the assembly of heavy equipment from stamped and formed steel parts. A recent development in arc welding is an electrode known as "Lightweld," which is used in conjunction with a C electrode and permits the joining of metals as thin as 22 gage. Some applications of arc welding and stamping combinations are found in the fabrication of large steel winches and overhead tram-rail conveying systems. Advantages are lighter construction, greater strength and economy. MS (11c)

Fabrication of Chromium-Nickel-Iron Alloys. J. S. Ewing. *Proceedings American Association of Textile Chemical Colorists,* 1931, pages 13-15; *American Dyestuff Reporter,* Vol. 20, Jan. 5, 1930, pages 15-17.

Alloy containing 8% Ni and 18% Cr is austenitic in character, non-magnetic. Tensile strength 90,000 lbs./in.^{2}. Yield point 45,000 lbs./in.^{2}. Hot working range is 2150° to 1750° F. It can be arc welded, gas welded, resistance welded, or spot welded. (11c)

Aluminum Welding. *British Machine Tool Engineering,* Vol. 6, July-Aug. 1930, page 123.

The flux employed to dissolve the oxide formed when welding Al must operate at the temperature of fusion of the Al. A good flux for Al and its alloys should have a melting-point of approximately 590° C. One containing Li and potassium chlorides, potassium bisulphate, and potassium fluoride is recommended. WHB (11c)

Bronze Welds Superior to Cast Iron. W. A. Duncan. *Canadian Machinery,* Vol. 42, Oct. 15, 1931, page 44.

The reliability of bronze welding for cast iron pipe repair is satisfactorily illustrated. It is also claimed that this method is rapid and economical. WAT (11c)

A Welding Phenomenon of Increase of Notch-Impact Toughness of Autogenous Welds (Ueber einen Schweissvorgang zur Erhöhung der Kerbschlagzähigkeit autogener Schweissungen). H. Buchholz. *Autogene Metallbearbeitung,* Vol. 24, Oct. 1, 1931, pages 288-291.

The notch-impact toughness depends greatly on the treatment the material has undergone. Tests were made on an iron with 38.7 kg./mm.^{2} tensile strength and 27.5% elongation with an original toughness of 24 mkg./cm.^{2}. The welding seam was almost closed by one bead and a thin covering layer which closes the seam and at the same time anneals it. The tests proved that this annealing is sufficient to convert the insufficient notch-impact toughness of the coarse-grained super-heated weld structure (of the first process) into fine-grained structure which has high impact toughness. Properly carried out work can increase the toughness 4-5 times and, with hammering, even 7-8 times. The ratio of the notch impact toughness so obtained to that of the original material can be 50-90%. Right-handed welding gave, in general, better results than left-handed welding. Double V-welds do not show quite as high values as single V-welds, probably because of an overheating since the annealing cover layer has to be applied on both sides. Ha (11c)

Atomic Hydrogen Arc Welding. J. T. Catlett (General Electric Co.). *Metals & Alloys,* Vol. 2, Nov. 1931, pages 272-276.

The discovery that a stream of hydrogen passing through the electric arc is dissociated into the atomic rather than the molecular condition has led to a new process of welding. Hydrogen in this condition is very active and contact with comparatively cold surfaces results in the release of the energy imparted by the arc and under very reducing conditions which would assist in the purification of weld metal. The details of equipment for this type of welding are described and applications of the method are discussed. Microstructures of welded material are shown. Resulting welds are strong, ductile and remarkably free from porosity. Unusual welds are obtainable by the method; pure Zn, precious metals, W and even quartz may be fused. Pb burning is easily accomplished. Application to nitralloy has been successful. WLC (11c)

The Standard Testing Methods for Welds (Die normalen Prüfverfahren für Schweissungen). Kautz. *Schmelzschweissung,* Vol. 10, Nov. 1931, page 227.

General remarks on the making of tests; which tests—tensile, bending or shear tests—should be adopted; how the specimens should be prepared; non-destructive tests with X-rays and radium. Ha (11c)

Some Tests of Gas-Welded Structural Joints. H. H. Moss (Linde Air Products Co.). *Welding*, Vol. 2, Oct. 1931, pages 667-672.

Paper presented at the Annual Meeting of the American Welding Society, April 1931. Details of tests made to aid a Special Building Code Committee of Detroit in its consideration of the oxy-acetylene process during the revision of the city code. TEJ (11c)

Arc-Welding Steel Building Frames. Frank P. McKibben. *Canadian Engineer*, Vol. 59, Dec. 30, 1930, pages 751-752.

A list of 35 questions and answers on arc-welding for building inspectors. VVK (11c)

Progress in Structural Welding During the Last Five Years. Frank P. McKibben. *Welding*, Vol. 2, Sept. 1931, pages 602-604.

Within the past 5 years, over 100 towns and cities have modified their building codes to permit the use of fusion welding in steel building construction. Many other cities are considering adoption of similar ordinances. Elimination of noise is welding's greatest asset. Accurate cost data is difficult to procure. Automatic welding equipment can be used advantageously for shop fabrication if sufficient tonnage is obtainable to warrant its installation. The publication of a good, concise handbook for structural designers; the adoption of a code to permit welding in New York City; and the publication of the American Bureau of Welding's test data on welded joints, would accelerate the adoption of welding on building frames. Data regarding shop and field welding of a nineteen story office building, are included. TEJ (11c)

"Arcogen." The Combined Oxy-Acetylene-Electric Welding Process. *Welding Journal*, Vol. 28, July, 1931, pages 198-200.

Condensed from a lecture by Dr. Munter of Frankfort (Main) before the German Acetylene Association at Eisenach, Oct. 18, 1930. Description of a welding process developed by "Griesogen" of Frankfort, Griesheim, in collaboration with the A. E. G. of Berlin. The process combines the use of the oxy-acetylene torch and a metallic electric arc, securing the advantages of both. Concentration of heat and freedom from distortion result from the use of the arc while the acetylene flame protects the metal from oxidation. The method of operation is described and illustrated. Photographs show hot and cold bent and forged test welds. All materials which can be oxy-acetylene welded may be treated by the Arcogen process. TEJ (11c)

Welding of Copper and Bronze Pipe. H. V. Inskeep (Linde Air Products Co.). *Journal of the American Welding Society*, Vol. 10, Oct. 1931, pages 21-24.

Paper presented at the Fall meeting of the American Welding Society in Boston, Sept. 1931. Tests of experimental oxy-acetylene welds on different sizes of pipe and tubing show that the short bell and spigot joint best fulfills building water distribution requirements. The investigation included commercial red brass pipe, Muntz Metal pipe and copper tubing. Types of welding rod used were Cu, high strength bronze and ordinary bronze. TEJ (11c)

Arc-Welding for Automotive Shops. W. J. Chaffee. *The Battery Man*, Vol. 12, Oct. 1931, pages 23-26, 51.

The great adaptability of the arc-welding process in all types of repair work occurring in garages is noted and emphasized. Ha (11c)

To do Good Welding on Monel Metal. W. E. Warner. *Canadian Foundryman*, Vol. 23, Feb. 1932, page 8.

A very brief statement of methods that should be adopted in the welding of Monel metal, either by the oxyacetylene or by the metallic arc method. OWE (11c)

Welding Field Storage Tanks. E. E. Dillman. *Oil Weekly*, Vol. 63, Nov. 6, 1931, pages 40, 42, 44, 46, 48.

Tanks as large as 80,000 barrels in capacity may be constructed with all seams welded and all rivets eliminated from their construction. Process used is described. Diagrams, testing methods and specifications are included. (11c)

Pressure Welding of Low-Carbon Steels with Theoretical Considerations on the Mechanism of Such Welding. C. R. Austin & W. S. Jeffries (National Tube Co.). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 451, Feb. 1932, 42 pages.

Describes an extended investigation of the factors influencing simple pressure welding. About 300 samples were welded by bringing the ends of rods together while at a welding temperature and applying definite pressures. The quality of the welds were determined by mechanical tests, macro- and microscopic examination and by measurements of the electric resistance. Welds were made in various atmospheres. It was concluded that satisfactory welds were dependent on breakage of the surface film. Many samples had high tensile strengths, but low shearing resistances, which was taken to indicate that welding had not resulted. It was concluded that simple pressure welding in air can not produce good welds. Detailed results are included in the several tables. 1 reference. JLG (11c)

Four Tunnels in New Arc Welded Water Line for San Diego. *Steel*, Vol. 88, Feb. 19, 1931, page 52.

A large transmission pipe line of 40 in. and 36 in. electrically welded steel pipe will bring water from the Otay reservoir to San Diego, Calif., a distance of 19 miles. This will supply 17,000,000 gallons daily. To construct the line, it was necessary to tunnel through four large hills. JN (11c)

Recent Developments in Oxy-Acetylene Welded Pipe Lines. D. E. Roberts. *Oil Weekly*, Vol. 61, May 8, 1931, pages 51-54.

Close procedure control, improved welding rod, better welding equipment, and new and improved methods of welding have all contributed toward the progress during 1930. (11c)

Future of Automatic Arc Welding in Boiler Work. G. H. Koch. *Boiler Maker*, Vol. 31, Feb. 1931, pages 34-36.

The mechanism used, speed of welding and different types of welds are discussed. The author believes that the all-welded boiler will soon replace the riveted boiler for high pressures. See *Metals & Alloys*, Vol. 1, Oct. 1930, page 801. Ha (11c)

Automatic Arc Welding of Steel Sheets. A. M. Candy (Westinghouse Elec. & Mfg. Co.). *Metals & Alloys*, Vol. 2, Nov. 1931, pages 262-265.

Where the seams are simple and of reasonable length steel sheets may be advantageously welded by the automatic arc. Time delay in changing electrodes is reduced by the use of coils of wire automatically fed to the arc. The advantages of the automatic arc are summed up in economy and reliability. Equipment of this type of welding is described and applications are discussed WLC (11c)

How Welds are Tested. John H. Crowe, A. B. Kinzel & W. B. Miller. *Heating, Piping & Air Conditioning*, Vol. 3, Dec. 1931, pages 1021-1024.

Describes and explains the tests of oxy-acetylene welds, which consist of visual examination, hammer and anvil nick-break test, free bend test for ductility, tension test, Brinell and Rockwell hardness tests, specific gravity, stethoscope test, γ- and X-ray tests, compression and drift tests, and hydrostatic tests. WAT (11c)

Oxy-Acetylene Welding of Alloy Steels and Irons. J. H. Critchett (Union Carbide Research Lab.) *Metals & Alloys*, Vol. 2, Nov. 1931, pages 253-256.

Late years have seen many demands made by industry and met by the development of new alloy steels. Best known of these are the Cr and Ni-Cr heat and corrosion resistant steels. The wide use of these materials has led to extensive studies of their welding. The flexibility of the oxy-acetylene torch makes it readily adaptable to the special problems of many alloys. These alloys form infusible oxides resulting in porosity if an oxidizing flame is employed; a flame too rich in acetylene results in carburization of the weld and adjacent material with consequent loss of corrosion resistance. A neutral flame is essential. A flux is desirable which will dissolve iron and chromium oxide and produce a slag of proper viscosity to readily float the impurities. The technique of butt and flange welding is discussed. The problems of individual alloys are discussed under composition headings, 4-6% Cr, 12-16% Cr, 16-20% Cr, 20-30% Cr, 17-25% Cr-7-12% Ni, 7-25% Cr-17-22% Ni, 18% Cr-8% Mn, 1-2% Mn and 12% Mn steels are discussed. The necessity for flux and heat treatment in each case is discussed. Welding high Si cast iron is accomplished with proper flux and rod of the same composition. WLC (11c)

Flexible Welds in Metal Bellows. Thos. O. Ford. *American Machinist*, Vol. 75, Sept. 10, 1931, pages 423-424.

Welds of bellow plates formed by atomic hydrogen process are homogeneous with the original plate in structure and react similarly to heat treatment. The inside of the joint is partly filled with water; the nickel steel expansion element is arc-welded to forged flanges. The test method for the finished bellows is described. Ha (11c)

A New Process of Oxy-acetylene Welding. T. W. Greene (Linde Air Products Co.). *Journal American Welding Society*, Vol. 10, Oct. 1931, pages 19-21.

Paper presented at the Fall Meeting of the American Welding Society in Boston, September, 1931. A description of the recently developed Lindeweld process, features of which are special flame adjustment to give a carbonizing flame, a special welding rod and back-hand welding technique. Physical properties of welds are tabulated. TEJ (11c)

The Yale University Group of Welded Buildings. Gilbert D. Fish. *Journal American Welding Society*, Vol. 10, Oct. 1931, pages 9-12.

Paper presented at the Fall Meeting of the American Welding Society in Boston, Sept. 1931. A description of 4 completely arc-welded steel frame buildings being erected at Yale University. Bids on welded construction were about 13% lower than riveted. About 8 ft. of shop welding and 4 ft. of field welding was done/ton of steel. Erection seats and bolts were used. Some photographic illustrations of joints are included. TEJ (11c)

Riveting (11d)

Pin Riveting in Boiler Work. *Boiler Maker*, Vol. 31, Feb. 1931, pages 30-33.

This is a new process developed by the Skoda Works in Pilsen, Czechoslovakia. First, the shank material is uniformly and simultaneously forced from both sides into the rivet hole upon which the material flows into the countersunk portion of the rivet hole. The 2 heads are formed on the plates simultaneously as a purely metallic contact is realized, i. e., without the interposition of any foreign matter. Practice has proven that pin rivets which have been snapped in accordance with this patented method show a tightness of 99% and do not require any subsequent calking. A special device for setting these pin rivets is described. Ha (11d)

A New Riveting Method for Light Metals, in Particular for Refinable Aluminum Alloys (Ein neues Nietverfahren für Leichtmetall, insbesondere für vergütbare Aluminiumlegierungen). *Aluminium, Hauszeitschrift V. A. W. Erftwerk*, Vol. 3, Apr.-June, 1931, pages 160-166.

Hot riveting usually destroys the great hardness of high grade aluminum alloys and other means were sought for a method of riveting which conserves all good properties of the light metals. This is of particular importance in the construction of airplanes. Only a cold riveting method could fill these requirements; such a method is described and illustrated with rivets also of light metal. Many precautions are necessary to insure complete tight fitting of the rivets and rivet heads to the material. A table shows the dimensions of rivets, heads, riveting iron, physical properties of the material used. From tests of riveted joints, it can be stated that the strength of a riveted joint does not depend on the manner in which the rivet head is made but, rather, on the kind of alloy and the thermal pretreatment and on the dimensions. Under certain conditions, annealing can increase the mechanical strength, somewhat; in special cases, a high shearing strength can be obtained by a steel sleeve over the light-metal rivet. The sleeve is fully protected against corrosion by the rivet tightly surrounding it. Ha (11d)

WORKING OF METALS & ALLOYS (12)

Melting & Refining (12a)

Melting Gun Metal. *Electrical Review,* Vol. 108, May 8, 1931, page 808.
Fuel consumption tests on small gas-fired and oil-fired installations for about 300 lbs. charge gave, as average cost/day, 10.3 pence for the gas furnace and a consumption of 0.5-1.5 gal. of oil/100 lbs. melt for the oil-fired furnace. This compares very favorably with the operating costs of electric furnaces. Ha (12a)

Mixing Metals. *Metallurgist,* June 1931, pages 81-82.
The preparation of an alloy of definite composition by melting together the requisite metals would appear to be a simple matter but in practice certain difficulties and complications have to be overcome, and these vary from one case to another, according to the characteristics of the metals used and of the final alloy. The "secret methods" claimed by vendors of proprietary materials can, of course, be duplicated by any competent metallurgist. The claim that "natural" alloys, whose constituent metals were reduced together from the ores, possessed advantages over the same alloy produced synthetically has been shown to be due to the presence of small amounts of other metals which were not taken into consideration when the synthetic alloy was made. Among bronze founders, the opinion is rather widely held that repeated remelting is necessary in order to produce good, homogeneous metal. The disadvantages of remelting are the tendency to absorb gases from the furnace atmosphere, the introduction of oxides and other compounds from the gases and from the refractories, contamination during repeated charging and subsequent manipulations and the loss of metal by volatilization or by oxidation. The advantages are the elimination of dissolved gases from the metal if it is cast into fairly large ingots and allowed to cool sufficiently slowly to undergo gas-elimination by the presolidification process and that it secures improved mixing. The former potential advantage is lost if the metal is cast into small chill ingots. Thorough mixing can be obtained by improving the present inefficient stirring prevalent in the non-ferrous foundry. VVK (12a)

Open-Hearth Furnace Control Discussed at Symposium in Buffalo. *Iron Age,* Vol. 125, June 26, 1930, pages 1889-1890.
Papers were read by R. W. Simpson, Bradley and Joseph F. Shadgen. For best results with furnace control deeper checkers are needed. Temperature is a most important factor in the furnace operation. A high degree of preheat speeds up operations. Dynamic control increases production, decreases fuel consumption, gives a longer furnace life and better metallurgical operation. Furnace atmosphere is important. CO recorders in stack are not a very satisfactory measure of combustion for open-hearth furnaces. VSP (12a)

Open-Hearth Operators Talk over the Problem of Making Good Steel. *Iron Age,* Vol. 126, Nov. 27, 1930, pages 1623-1626; **Quality Control, Alloy Contamination in Making Open-Hearth Steel.** Dec. 4, 1930, pages 1701, 1745-1746; **Open-Hearth Men Consider Furnaces, Fuels and Mold Washes.** Dec. 11, 1930, pages 1777-1779.
From 13th semi-annual session of the open-hearth conference of the iron and steel division of the American Institute of Mining and Metallurgical Engineers at Cleveland, Nov. 20, 1930. Program was divided into 3 sessions, devoted to open-hearth operation, combustion control and quality control and also including a discussion of refractories. Use of superheated steam at about 650° F. showed a saving of 2 gal. of oil to a ton of steel as compared with steam for atomizing, but without superheat. Little advantage in superheat is noted, so far as flame temperature is concerned. Troubles with bifurcated spout may be avoided by keeping tapping hole of furnace straight. One operator uses tilting furnaces on account of high P content in his Fe. Large heats give a decided saving in operating cost, because there is less time required for each ton of steel; less bottom material; greater outflow of steel hourly, and labor cost lower for each ton. Time is gained in the making of a heat when a high percentage of hot metal is used in place of a high percentage of scrap. Size of ladles is increasing. Deep slag pockets are advantageous. Refractories suitable for use with temperatures of 3500° to 4000° F. are needed. Progress has been made in better silica brick. Rolling mill committee recommended beginning blooming with small draft, turning ingot 90°, after every 2 passes. Best results obtained by passing ingot through rolls at between 2150° and 2200° F. High S steel should be poured on "cold side" and rolled on "hot side." Liberal stirring with rods recommended in refining process. Progress report on alloy contamination of open-hearth steel was given by Dr. C. H. Herty, Jr. Cost of open-hearth roofs, close flame control is essential, advantages of using luminosity flames, mold and stool coatings were other topics discussed. VSP (12a)

Re-melting. *Metallurgist,* Nov. 1930, pages 162-163.
The present restrictions in current specifications on the use of scrap in the manufacture of brass should be retained; any variation therefrom should be arranged privately by the manufacturer and the customer. VVK (12a)

Rolling (12c)

The Arrangement of Passes on Stationary 3-High Blooming Mill Rolls (Ueber Anordnung von Kalibern auf festliegenden Trio-Blockwalzen). T. Dahl. *Stahl und Eisen,* Vol. 51, Oct. 1, 1931, pages 1228-1232.
The author shows that in rolling special steels on 3-high mills, the distortion of the rolled product is due to a non-uniform distribution of the upper pressure.
Generally speaking, an unsuitable arrangement of the passes on stationary 3-high rolls is sometimes to be found. The manner of obtaining an equalization and a diminishing of the upper pressure can be attained. The described method diminishes the distortion of the rolled stock. GN (12c)

Sheet Mill Practice. R. J. Wean. *Blast Furnace & Steel Plant,* Vol. 19, Feb. 1931, pages 261-263.
Discussion of the economies achieved by newer methods of continuous strip mills and the adaptation of existing equipment to meet present day competition without creating undue technological unemployment. A chart is given for figuring the possible savings. Ha (12c)

Shearing & Punching (12e)

Punching and Forming in the Strip. Chas. F. Smith. *American Machinist,* Vol. 75, Oct. 1, 1931, pages 522-523.
Discussion of the method best suited to least handling the strips and pieces punched from it. Ha (12e)

Machining (12g)

Greater Tool Life by Efficient Refrigeration. *Houghton's Black & White,* Vol. 3, Mar. 1931, pages 10-12.
A few practical suggestions for the arrangement for cooling tools and the selection of coolants. Ha (12g)

Turning Pistons. *Automobile Engineer,* Vol. 21, Apr. 1931, page 134.
A diamond-tipped tool is used on light alloys in cases where a high degree of finish is required. Ha (12g)

Progress in Milling Practice. *Automobile Engineer,* Vol. 21, May 1931, pages 194-195.
A few interesting examples of recent milling machinery which has speeded up production very considerably. Ha (12g)

Machinability of Metals. Alexander H. d'Arcambal. *Canadian Chemistry & Metallurgy,* Vol. 15, Oct. 1931, pages 270-271.
The relative machinability of steels is in the order: cold drawn Bessemer screw stock; open-hearth Bessemer screw stock; high-S; low-S; high-Mn; and basic open-hearth. The high machinability and finish of high-Mn steels gives them wide use in spite of their high cost. It is now believed that the coarser the grain the more readily machinable are the materials. High-Mn steels, sulphonated cutting oils, and Cr-plated tools are recommended. A field is seen for tantalum carbide-tungsten-carbide tool material. WHB (12g)

Milling with Tungsten Carbide Tools. *Engineer,* Vol. 151, June 12, 1931, page 659.
Brief comment on machining operation described in publication of Kearney and Trecker Corporation, Milwaukee. Milling is done with an inserted tooth cutter on a cast-iron pump body, one end of which must be faced. Due to its form, there are many interruptions but chipping of corners must be avoided. Compares performance of high-speed steel, Stellite, and tungsten carbide. Stellite feed per min. is 75% faster than high-speed steel. Tungsten carbide feed per min. is 170% faster than high-speed steel and 55% faster than Stellite. LFM (12g)

The Influence of Shape and Magnitude of the Section of the Chip on the Result of Measurements of Cutting Pressures on Turning Tools (Der Einfluss von Form und Grösse des Spanquerschnitts auf das Messergebnis bei Schnittdruckmessungen an Drehwerkzeugen). B. Windmueller. *Die Messtechnik,* Vol. 7, June 1931, pages 150-152.

At first it is shown how the pressure exerted on the tool in cutting the material is resolved into 3 components, the principal cutting pressure acting vertically, the feed pressure acting in axial direction of the working piece, and the back-pressure acting in transverse direction of the axis of the piece, usually in the direction of the cutting tool. The arrangements to measure these pressures by Taylor, Schlesinger, Losenhausen Okochi and Okoshi, and the measurement of the torque produced in cutting are described. It is shown that, because of the construction of these arrangements shape and magnitude of the chip influences the result. The inaccuracy due to this influence can be reduced by taking into account the depth of the cut. 2 examples illustrate the method. Ha (12g)

Machining Duralumin. John Younger & W. R. Jenkinson. *American Machinist,* Vol. 75, Aug. 13, 1931, pages 269-271.

A series of tests were made to determine the power consumption in machining both cast and wrought duralumin of 55,000-63,000 lbs./in.^{2} tensile strength and a Brinell hardness from 90 to 105. This material was used in place of steel, making possible a saving of about 3/5 of the weight. Cutting tests were made with different cutters and the horse power consumed measured at different speeds. Charts were made up showing the consumption at different speeds and feeds. Ha (12g)

Some Experiences with Tungsten-Carbide Tools. K. F. Smith. *Machinery,* Vol. 37, Feb. 1931, pages 415-416.

General remarks on feed, speed and angles of grinding as experienced in the Naval Air Station, San Diego, Cal. The output/man was greatly increased by these tools. Ha (12g)

The Cutting of Outer Threads with Automatically Opening Cutter Head (Das Aussengewindeschneiden mit selbstöffnendem Schneidkopf. Ein Beitrag zur Frage der Zerspanbarkeit von Eisen und Stahl). K. Schimz. *Archiv für Eisenhüttenwesen,* Vol. 5, July 1931, pages 35-44.

7 different materials with varying C, Si, Mn, P, and S contents were used during the experiments. The results show that the cutting of inner and outer threads are 2 types of machining which require different steels. The geometrical shape of cutterhead and dies limit the cutting performance. The performance is closely related to cutting velocity, cooling, angles of tool, diameter and properties of the material. Actual cutting is done by the teeth of the ground side. At low cutting velocities, the wear of the edge of the cutters is independent of the composition of the tool. Practical results with a cutting velocity of 6 m./min. show a torn surface at the end of the thread. The wear of the dies are in the first place dependent on the C content of the material. The increase of tensile strength caused by P is of minor importance. No relation exists between wear of the dies and length of the chips. The shortest chips are obtained with the highest C, P and Mn contents. GN (12g)

Optics in Metal Working. Ken G. Niblack. *American Machinist,* Vol. 75, Aug. 6, 1931, pages 225-228; Aug. 13, 1931, pages 272-273; Aug. 20, 1931, pages 307-309; Aug. 27, 1931, pages 346-347; Sept. 3, 1931, pages 380-382.

This series of articles explains the fundamentals of optical systems, magnification, deflection, refraction and describes in detail the instruments for testing materials and processes, such as micrometer microscopes, spectroscopes, contour projector, optical drill gage and optical flats. Ha (12g)

The Cutting Carbides. Frank W. Curtis (Kearney & Trecker Corp.). *American Machinist,* Vol. 74, May 14, 1931, pages 755-757.

Abstract of a *Society of Automotive Engineers Production meeting paper,* entitled "Latest Developments of Faster Milling with Tungsten and Tantalum Carbide Cutters." Discusses design of the milling machines, speeds and operating practices. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 313. RHP (12g)

Deep Drilling of Small Holes. J. T. Towlson. *American Machinist,* Vol. 75, Aug. 6, 1931, pages 248-249.

The drill is clamped into a chuck so that it protrudes only slightly and is fed by hand into the work. When the drill has penetrated the work as far as it can go, the chuck is screwed back and the drill is set out farther, thus drilling in steps. Ha (12g)

The Story of Carboloy. Part III. *Carboloy,* Vol. 2, May 1930, pages 2-4.

This installment deals with the proper setting of Carboloy (tungsten carbide) bits for tools and the best angles for cutting the different materials. The advantage of using larger shanks instead of small bits is pointed out. The bits are brazed by hydrogen-copper to the steel shank, with but very little Cu to be employed, but ample area must be provided for correct braze. Ha (12g)

Turning by Templet. *American Machinist,* Vol. 75, Aug. 13, 1931, pages 281-282.

Description of arrangement of templets. Ha (12g)

Drawing & Stamping (12h)

Machines for Hot-Forming and Stamping Nonferrous Metals. J. I. Bernitz. *Metal Stampings,* Vol. 4, Apr. 1931, pages 333-336.

Most commonly used machines for hot forming of nonferrous metals, particularly brass, are: (1) drop-hammer, (2) friction screw embossing press, (3) crank or eccentric shaft press and (4) hydraulic press. Drop-hammer has not been as successful with brass as with steel. It has a tendency to spread the material rather than to force it down into the cavities of the die. Almost any kind and size of hot forgings can be made on the friction screw press. Proper penetration to the center of the slug and the desired spreading effect are obtained with this press. Eccentric presses are limited to hot forming of small and medium sized articles requiring little deformation. Hydraulic press is suitable for materials which are handled at low temperature and require a slow deforming spread. MS (12h)

Experiments in Wire Drawing: The Drawing of Non-Ferrous Wires. Francis & Thompson. *Engineer,* Vol. 152, Oct. 2, 1931, pages 358-359.

Astract of a paper read before the Institute of Metals, Zurich, Switzerland, Sept. 15, 1931. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 314. LFM (12h)

Testing Deep Drawing Qualities of Sheet Metal. H. W. Gillett. (Battelle Memorial Institute) and discussion by C. L. Eksergian (Budd Wheel Co.). *Metals & Alloys,* Vol. 4, Oct. 1931, pages 214-222.

73 references are cited. The variables involved in die and press design are enumerated and discussed, and the variables in the quality of the sheet metal. Various tests for hardness and deformation under standard conditions are discussed with reference to their control of the quality of sheet to be used. The standards of tests applicable to one plant or operation must be applied elsewhere with caution and careful study. Mr. Eksergian discusses specifically the manufacture of automobile parts by deep drawing. WLC (12h)

Pickling (12i)

The Pickling of Metals. *Heat Treating & Forging,* Vol. 17, Oct. 1931, pages 959-960.

Solutions, maintenance of acid solution, pickling time, temperature of baths and catalyzers are described. Ha (12i)

Makes Pickling Tanks of Rubber and Brick Linings. *Iron Age,* Vol. 128, Aug. 6, 1931, pages 378-379.

Vulcanized rubber in combination with steel and masonry is being offered by the B. F. Goodrich Rubber Co., Akron, Ohio. VSP (12i)

Cold Working (12j)

The Cold Finishing of Steel Bars. J. R. Miller. *Blast Furnace & Steel Plant,* Vol. 19, Feb. 1931, pages 264-267, 276; *Heat Treating & Forging,* Vol. 17, Jan. 1931, pages 40-43, 49.

Discussion of the manufacturing process for cold rolling and cold drawing and the cost for producing certain goods. The steel used in these processes is usually open-hearth steel of 0.26-0.32% C and 0.60-0.80% Mn. Ha. (12j)

Strain-Hardening of Plastic Metals. E. V. Crane. *Iron Age,* Vol. 128, July 23, 1931, pages 250-253; Aug. 20, 1931, pages 498-499, 543-545.

Plasticity of metals is essential as a prerequisite for press operations. How the physical properties of various metals usually used for such treatment are affected by repeated cold working is shown by diagrams and tables. Successive strain-hardening, followed by softening under annealing and, thus, working back and forth between a hard condition and a soft condition is explained and the limits to which strain-hardening may be safely carried are outlined and illustrated in curves for bronze, carbon steels, Cu and Al. It is essential that cold working does not go beyond the limit of plasticity, since, otherwise, fracture will result. Cold working, however, increases the elastic limit and also the yield point which are the vital elements in plastic working. Ha. (12j)

Lead Coatings as Lubricant in the Cold Working of Metals (Emploi du plombage dans le travail a froid des métaux). G. De Dudzeele. *Congres International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 499-506. 8 figures.

In order to avoid annealing between passes and the loss of metal resulting from the necessary pickling, lead coating of seamless tubing and other cold-worked steel products, is advised. The Pb is not really a lubricant, since it takes slightly more power to cold work the lead coated products, but it prevents seizure of the tubing in drawing, and less lubricant is required. Seizure is especially notable with alloys high in Cr. Some high Cr steels can scarcely be worked without the lead coating. The Pb is applied by fluxing and dipping. It is applicable to brass, bronze, cupro nickel, nickel brass, etc., as well as to steel. In drawing tubes of 1% Cr, ¼% Mo, 4 passes on coated steel produced the same result as 5 passes on uncoated steel. Apparatus for hot-dipping to produce the lead coating is illustrated. Removal of the Pb is mentioned in the cost estimates tabulated, but the method of de-leading is not described. HWG (12j)

Machine for Cold-Forming Metal Strip. *Brass World,* Vol. 27, Sept. 1931, page 198.

A new method in cold-roll forming machinery for metals is announced by Kane & Roach, Inc., Syracuse, N. Y. The machine will manufacture a patented retainer strip, used in installing gypsum board. WHB (12j)

Cold Heading Die Life. A. S. Jameson. *Metal Stampings,* Vol. 3, Oct. 1930, pages 927-928.

Abstract of paper read before the American Society for Steel Treating, Sept. 22-26, 1930. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 272. MS (12j)

Cleaning (12k)

Cleaning Scale and Rust from Steel Parts. *Machinery,* Vol. 37, Jan. 1931, pages 375-376.

A "bright dip" electrolytic pickling process is described. The composition of the liquid is not given. Ha. (12k)

Electrolytic Metal Cleaning without Corrosion. *Chemical & Metallurgical Engineering,* Vol. 37, Oct. 1930, pages 634-635; *Metal Cleaning & Finishing,* Vol. 2, Oct. 1930, pages 899; *Maschinenkonstrukteur Betriebstechnik,* Vol. 64, May 10, 1931, page 111.

A new method, the Bullard-Dunn method, patented by the Bullard Company, Bridgeport, Conn., claims the purification of metal surfaces from oxides, scale, etc., which are present. It is suitable for iron and steel as well as for non-ferrous metals. MS&MAB (12k)

Cleaning (12k)

Trichlor-ethylene as Degreasing Material in the Metal Industry (Trichloraethylen als Entfettungsmittel in der Metallindustrie). GEO. WOLFF. *Oberflächentechnik,* Vol. 7, Aug. 19, 1930, pages 154-155.

The disadvantages of removing grease by boiling in lyes are explained. Trichlorethylene is a compound absolutely non-explosive and non-inflammable. It boils at 87° C. and, therefore, can be readily recovered by distillation from the grease and oil. It is superior to benzine in solving fats and oils, even rosin, pitch, sulphur, wax and paraffins. It does not etch or attack metals. If inhaled in great quantities, it has a narcotic effect with, however, no harmful after effects. Workmen, working with trichlorethylene, should be protected against inhaling. Installations for washing with this preparation and subsequent drying are described. Ha. (12k)

Polishing and Grinding (12l)

Sharpening Reamers. L. M. RICHARDS. *American Machinist,* Vol. 75, July 23, 1931, page 177.

Description of a method which removes the usual uncertainty of sizing, and increases the life between grinds tenfold. It is accompanied by circular grinding in the usual manner and then backing off to within 0.006-0.01 in. Ha. (12l)

Magnetic Chucks Keep Pace with Modern Surface Grinders. F. L. SIMMONS. *Iron Age,* Vol. 128, Oct. 29, 1931, pages 1114-1115, 1138.

The advantages of magnetic chucks for holding magnetic materials while being ground or polished are noted and a few constructions are illustrated. A much greater quantity of material may usually be handled in the same time that is required by mechanical holders. Ha. (12l)

Grinding Direct from the Drawing. O. P. VAN STEEWEN. *American Machinist,* Vol. 75, Sept. 3, 1931, pages 367-371.

Description of a machine which makes it possible to finish grind directly from the hardened piece the desired profile according to a drawing magnified 50 times, even if limited by straight or curved lines. It consists essentially of 3 parts, the work slide, grinding wheel head and pantograph with microscope and drawing board. The microscope facilitates observation of the work and the tool. The machine works accurately to microscopic tolerances. Ha. (12l)

Grinding Fixtures for a Threading Die. C. R. RANNEY. *American Machinist,* Vol. 75, Aug. 6, 1931, pages 241-245.

Detailed description of the precision tools for grinding threading dies and their set up. Ha. (12l)

Tool Grinding Control. P. E. GARLENT. *American Machinist,* Vol. 75, Oct. 15, 1931, pages 599-600.

A central system supplements the individual tool rooms that serve their respective departments so that uniform tool grinding throughout the plant is guaranteed. This system is in use at the Timken Detroit Axle Co. Ha. (12l)

Controlled Structure of Grinding Wheels. *Western Machinery World,* Vol. 22, Sept. 1931, page 399.

A new method employed by the Norton Co., of Worcester, Mass., for manufacturing grinding wheels, which makes possible finer refinement of grinding action and closer duplication of wheels is described. Regulation of the arrangement of abrasive, bond and pore space to produce a specific structure for a particular grinding operation, without changing the grain or grade is the essential feature of this new method. It permits about 12 structures without change of grade in a wheel, though for commercial practices not all of these are necessary or employed. The method is applied by controlling the volume percentage of the constituent parts of a wheel. WAT (12l)

Finishing Pipe Straps (Rohrschellenfertigung). KARL DEININGER. *Das Werkzeug* (supplement to *Maschinenkonstrukteur-Betriebstechnik*), Vol. 7, May 10, 1931, pages 105-106.

In producing pipe straps it is desirable that as few single operations as possible be necessary. The production of this attachment by means of a combined tool is explained, special attention being given to the present-day means of polishing. MAB (12l)

Cam Grinding. *Automobile Engineer,* Vol. 21, Feb. 1931, pages 64-65.

A recently introduced cam grinding attachment of the Churchill Machine Tool Co., Ltd., is described. It is arranged to give an even surface speed by retarding the rotation of the work as it swings away from the grinding wheel whilst accelerating the speed at the opposite motion. Ha (12l)

Advantages of Mechanical Lapping Over Hand-Lapping. *Grits & Grinds,* Vol. 22, June 1931, pages 2-7.

Tests made over 2½ yrs. with plug gages of 4 different manufacturers gave evidence that in every instance the mechanically lapped gage plugged more holes than the hand-lapped gage. It also indicates that the maintenance costs were reduced. Ha. (12l)

Photomicrographs Show Superiority of Mechanically Lapped Gages. *Grits & Grinds,* Vol. 22, June 1931, pages 7-11.

A collection of microphotographs taken of a hand-lapped gage that had to be discontinued after 8000 holes while the mechanically lapped gage stood up to 25,389 holes. Ha. (12l)

The Polishing of Aluminum and Brass. *Metal Industry,* N. Y., Vol. 29, May 1931, page 208.

The details are given for the rough and fine polishing of castings, etc., of aluminum and of brass. PRK (12l)

Dressing Rolls in Aluminum Rolling Mills by Hand Grinding. R. J. ANDERSON. *Rolling Mill Journal,* Vol. 5, Dec. 1931, pages 763-766.

The principles and practice employed in the maintaining of fine surface finish on rolls used for rolling Al sheet and foil are discussed and the tools described. Ha (12l)

Improved Quality and Reduction of Costs in Polishing. (Gütesteigerung und Kostensenkung beim Schleifen.) KUNG. *Maschinenbau,* Vol. 10, Feb. 19, 1931, pages 111-113.

The basic questions in the discussion of polishing are worked out. Several instances are given where provision is being made for calculated data. MAB (12l)

Experiments in Metal Polishing. EDWIN M. BAKER & GEORGE E. HOLBROOK. *American Machinist,* Vol. 74, May 14, 1931, pages 749-751.

Condensed from a paper before the Electrochemical Society, Birmingham, Ala., Apr. 1931. See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 21. RHP (12l)

Cleanliness of Polishing Abrasives. H. R. POWER. *Metal Cleaning & Finishing,* Vol. 3, Jan. 1931, pages 43-44.

The author notes that the presence of oily dust in abrasive grains lowers their efficiency. The abrasive dust formed by attrition, however, does not have any ill effects. The tests are described. Ha (12l)

Burnishing with Tungsten Carbide. F. J. SANDERS. *Machinery,* Vol. 37, May 1931, pages 674-676.

Description of a machine in which cams are burnished accurately to size. Production costs could be reduced 80%. Ha (12l)

Comparison of Two Grinding Machines. (Vergleich zweier Schleifmaschinen.) E. SACHSENBERG. *Maschinenbau,* Vol. 10, Jan. 1, 1931, pages 12-14.

Two kinds of handles for a hand-grinding machine are compared for their economic values and for their suitability for the operator. Tests are made. MAB (12l)

Double-wheel Grinding Method for Cast-iron and Hard-alloy Cylinder Liners. *Abrasive Industry,* Vol. 12, Sept. 1931, pages 36-37.

The introduction of centrifugally cast and hard-alloy liners for bores of automotive engine cylinders brought new problems in the finishing of the outer surfaces. It is essential for the liner to make a metal-to-metal contact with the bore of the cylinder. Grinding has proved to be the most satisfactory method, but difficulty has been experienced in the holding of the work and the prevention of distortion during grinding. The expanding arbor fitted to the special machine has proved successful in grinding this work because the adjustment is sensitive and eliminates the possibility of distortion. WAT (12l)

Controlled Structure of Grinding Wheels Means Better Grinding. *Grits & Grinds,* Vol. 22, June 1931, pages 11-12.

The Norton Co. manufactures their grinding wheels under strict control of the abrasive grain, the bonding material for holding the grains together and, also, the pores formed by the grain and bond. In this manner an absolutely uniform product of any desired structure can be obtained. Ha (12l)

Coloring (12m)

Black Coloring of Wire Products, a Description of German Low Cost Processes. *Wire & Wire Products,* Vol. 6, June 1931, pages 228-229, 250.

The black coloring of nails, hair pins, safety pins, wire eyes, wire clips and other products is intended partly to cover the shiny metal and partly to increase the durability of the article. Nails are usually burnt in oil or fat; for pins and needles, a purely chemical coloring in a solution of 10 g. of sulphate of copper, 15 g. stannous chloride, 20 g. hydrochloric acid in 1 liter of distilled water is employed. Small iron ware is colored in the diamond black oxide process; they are dipped for a short time in a hot coloring bath to obtain a deep black matt coloring. The polish is obtained by placing the articles in sawdust moistened with oil and rotated in a drum. Some other processes, using lyes or sulphur, are described. Mass articles are often colored black by lacquering; spirit as well as soap lacquers may be used. Fat lacquers are particularly durable. Methods of spraying and drying are described in detail. Ha. (12m)

Sandblasting (12n)

Overloading Reduces Efficiency in Sandblast Barrel Machines. LOUIS D. PEIK. *Foundry,* Vol. 59, Sept. 15, 1931, pages 53, 55.

Results of a series of tests indicated that the following causes influence cleaning production: (1) depth of loading, (2) capacity of barrel, (3) angle of blast, (4) speed of barrel and (5) mixture and class of work. VSP (12n)

Progress made in the Removal of the Crust of Cast Steel (Progres réalisés dons le décapage de l'acier coulé). A. SISSON-LEHMANN. *L'Usine,* Vol. 40, July 31, 1931, page 33; *Revue Fonderie Moderne,* Vol. 25, Aug. 25, 1931, pages 314-316.

Sand blasting for cleaning cast steel pieces of the hard skin due to vitrified molding sand is still a fairly neglected and very expensive item of a steel foundry. In 2 French steel foundries, good results have been obtained by the replacement of sand in the sand blast by steel grit. The advantages claimed are diminution of cost of transportation, purchasing and storing of the special sand for blasting purposes which must also be dried and sifted. Steel grit can be had easily in the steel work; it is powdered when blown on to the casting; its effect is, however, less rapid than that of sand. For each ton of steel cleaned, about 2-4 kg. of steel grains were used. The economical advantages are discussed in much detail. Ha. (12n)

The Advantages of Steel Grit and Shot for Sand-Blasting Work. G. H. ZIRKER. *Engineering Progress,* Vol. 12, Apr. 1931, pages 92-94.

In using a Si-Mn steel grit for sand blasting operations, removing rust and grease, several advantages over quartz sand are obtained. The life of steel as grit is about 60 times that of sand, which means that considerably less expense for storing, transporting and drying is involved. The high resistance to wear results in nearly dustless operation, so that the disagreeable dust removal is reduced considerably. Air consumption is from 10 to 40% lower. The most effective pressure was found to be from 1 to 3 atmospheres for finer grades and between 3 and 6 atmospheres for the coarse grades, whereas quartz sand requires between 0.5 and 3 atmospheres. Several examples were cited where operation with steel grit led to improvement and economies. Ha. (12n)

DEFECTS (13)

A Suggested Method of Determining the Cleanness of a Heat of Steel. Samuel Epstein (Battelle Memorial Institute). *Metals & Alloys*, Vol. 2, Oct. 1931, pages 186-191.

The author points out that chemical methods are supplanting microscopic means of determining the cleanness of steel. This he attributes to the failure of the metallographer to realize the importance of sampling. 2 classes of inclusions exist: small, fairly uniformly distributed inclusions and segregations or large inclusions occuring at random. 3 methods appearing recently in the literature are reviewed. The proposed method developed at the South Chicago plant of Illinois Steel Co. has as its first consideration adequate sampling. Systematic sampling from stated portions of ingots and uniform reduction and size of specimens is followed. The results of such a method are described. The technique of polishing for study of inclusions is important. WLC (13)

Research on Wrought-Iron Chains. The Nature of Defective Lamination in Wrought-Iron Bars and Chain Links. H. J. Gough & A. J. Murphy. *Iron & Coal Trades Review*, Vol. 122, May 8, 1931, pages 731-736; *Engineering*, Vol. 151, May 22, 1931, page 566.

The fractured surface of a bar or chain link sometimes reveals the presence of one or more laminations exhibiting a brittle, coarsely crystalline appearance, the remainder of the section having the normal appearance of ductile wrought iron. This phenomenon was investigated; test methods, preparation of specimens are described and graphical results given. See *Metals & Alloys*, Vol. 2, Nov. 1931, page 273. Ha & LFM (13)

Elimination of Transverse Fissures in Steel Rails. *Iron & Steel of Canada*, Vol. 14, Aug. 1931, pages 127-128.

Reference is made to a process which has been perfected by I. C. Mackie of the Dominion Iron & Steel Company for preventing the formation of transverse fissures in steel rails. The invention relates to the discovery of the precise stage in the production of rails when too rapid cooling results in "shatter cracks." OWE (13)

Corrosion and Radiator Solder Seam Failure. W. H. Wilson. *Automotive Industries*, Vol. 65, July 18, 1931, pages 84-87.

Some years ago there was much talk, particularly in the field, about the corrosive effects of anti-freezes in general on the metals of the cooling system. Little definite knowledge was at hand concerning the action of water, heat, aeration, anti-freeze on solder, copper, iron, brass, aluminum and rubber—the materials most commonly used in cooling systems. The processes of radiator clogging and radiator disintegration had not been intensively studied. All these subjects have been under investigation. The conclusions can be summarized as follows: 1. The solder used in the manufacture of the five most commonly used makes of cellular radiators has considerable resistance to corrosion. Road shock and vibration are evidently necessary to produce the type of solder failure usually found in automobile radiators in the field. 2. Water can have a very severe corrosive action on brass radiators. Anti-freeze solutions caused no apparent corrosion of brass, whereas ordinary water corroded brass water passages sufficiently to cause the appearance of many leaks in the form of small, round holes, or weak spots down the center of the ribbon. (13)

CHEMICAL ANALYSIS (14)

Rapid Method for the Determination of Vanadium in Ferro-Vanadium (Schnellverfahren zur Bestimmung des Vanadins in Ferrovanadin). A. Eder. *Stahl und Eisen*, Vol. 51, Oct. 1, 1931, pages 1236-1237.

The described American titration method for V offers the disadvantage that at room temperature V_2O_4, towards the end of the titration with permanganate, has too low a velocity of oxidation so that the end of the titration cannot be determined accurately. This disadvantage cannot be eliminated by titrating with an excessive amount of permanganate and re-titrating the excess of permanganate with arsenic acid. This new titration method is described in detail and illustrated by an example. GN (14)

Application of the Spectrograph to the Analysis of Non-Ferrous Metals and Alloys. H. W. Brownsdon & E. H. S. van Someren. *Engineer*, Vol. 152, Oct. 2, 1931, pages 359.

Abstract of a paper read before the Institute of Metals, Zurich, Switzerland, Sept. 15, 1931. See *Metals & Alloys*, Vol. 2, Nov. 1931, page 274. LFM (14)

The Detection of Foreign Elements in a Metal by Spectral Analysis (Sur la recherche par l'analyse spectrale des éléments étrangers dans un métal). Lucien Amy. *L'Industrie Électrique*, Vol. 40, Jan. 10, 1931, pages 20-21; *Comptes Rendus*, Vol. 191, Dec. 1, 1930, pages 1049-1050.

Description of a very sensitive method which consists in photographing 2 spark spectra side by side. The one is between 2 pieces of the metal to be investigated and the other between 2 pieces of the pure metal. The procedure and the precautions to be observed are described in detail. Ha (14)

Fundamentals of Chemical Analysis as Applied to Electroplating. L. C. Pan. *Metal Cleaning & Finishing*, Vol. 3, Jan. 1931, pages 37-40; Feb. 1931, pages 129-132.

Methods and apparatus for controlling the composition of plating baths, reading analysis charts and making up standard reagents are described. The gravimetric and volumetric methods are explained. Ha (14)

The Determination of Nickel and Chromium in Metal Alloys and Cast Iron. (Die Bestimmung von Nickel und Chrom in Metallegierungen und Gusseisen.) V. Pestelli. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Nov. 13, 1931, page 883.

The existing methods are reviewed and new ones discussed to permit a greater accuracy. No definite conclusions as to the best methods have been arrived at. Ha (14)

ECONOMIC (16)

The Significance of Specifications in Purchasing Steel. P. Parke (The Pullman Co.). *Railway Age*, Vol. 91, Dec. 5, 1931, pages 867-868.

Material specifications are of particularly economic importance to the large steel user in that: (1) They are evidences of the fact that thought and study have been given to the severe requirements for which a particular material is intended. (2) They constitute a standard for measuring and checking materials as supplied. Such checking insures against delay and waste in fabrication which would occur with improper materials. (3) They are invaluable to the large consumer who commonly draws his material from several sources of supply. Their proper application, in such cases, insures that materials from different sources will be of uniform and suitable quality. (4) They promote the highest and best use of materials for each particular purpose. (5) They open a field of fair competition. WAT (16)

Production Economy in Iron and Steel Works. Otto Cromberg. *Iron & Steel of Canada*, Vol. 14, May 1931, pages 77-80, 91; abstracted in *Engineer*, Vol. 151, May 15, 1931, pages 534-535.

Paper read before the Iron & Steel Institute May 7-8, 1931. Only the first part is given in this issue of Iron & Steel of Canada. It includes a discussion of a fundamental study of the laws of factory management which has been carried out in Germany since the war. The article is accompanied by 5 tables and an output diagram. The tables show the results of time studies with various machines and men; the curves show the improvement in production resulting from strict supervision of contract outputs and of repair work. See also *Metals & Alloys*, Vol. 2, Nov. 1931, page 276. OWE (16)

Reorganization of the Iron and Steel Industry. *Engineer*, Vol. 151, May 8, 1931, page 508.

Short note commenting on memorandum issued by the National Federation of Iron & Steel Manufacturers. Cites instances of the effort being made to improve conditions in the iron and steel industry both in Great Britain and in the Dominions. Gives names of some of the companies which have combined forces to take advantage of large scale production methods. LFM (16)

The Metal Industries in the North. Trade Conditions in the West of Scotland. *Metal Industry*, London, Vol. 38, May 1, 1931, pages 449-451.

Not only has the world wide depression affected the ferrous and non-ferrous industries, but also have the decline of export trade, curtailment of Admiralty work, lack of expansion in the home markets, and heavy local taxation. PRK (16)

Steel for Tinplate. *Tin*, Sept. 1931, pages 3-6.

An economic investigation of the Welsh tinplate industry which is said at present to be unable to compete with tinplate from other countries on account of the manner of making the steel by the basic Bessemer process instead of by the open-hearth system as in other countries. A possible remedy is seen in the duplex process. Ha (16)

Reduction and Refining of Lead in 1930. *Mining & Metallurgy*, Vol. 12, Jan. 1931, pages 7-8.

Review of the progress, especially in the new Australian plants. Ha (16)

The Continental Steel Cartel. *Engineering*, Vol. 131, Jan. 23, 1931, pages 114-115.

Editorial commenting on recent decision of the Continental Steel Cartel to reduce the total quota. This is an attempt to assist the recovery of the Continental steel industry from the present decline. For the first quarter of 1931, a reduction of 30% will be made in the quota. LFM (16)

Steel, Confident Recovery Near, Girds for Tenser Rivalry. E. C. Barringer. *Steel*, Vol. 88, Jan. 1, 1931, pages 241-244, 254.

The 10 largest producers of steel have spent the year 1930 in strengthening their competitive positions with many new subsidiary relationships involving merger or purchase. The Bethlehem Steel Corp. has expanded considerably, extending its influence westward by absorbing Cambria and Lackawanna, and by attempting to merge with the Youngstown Sheet and Tube Co. The U. S. Steel Corp. has built 21 new open-hearth furnaces and greatly improved its facilities in the Chicago, Pittsburgh, Lorain and Cleveland Districts. The greatest competition between U. S. and Bethlehem promises to be in the field of structural steel with welded steel pipe a likely close second. JN (16)

Gold and Silver in 1929. J. P. Dunlop. *Mineral Resources of the United States, 1929, United States Bureau of Mines*, Oct. 1931, pages 877-920. Part 1.

Gold production in the U. S. in 1929 was 2,208,386 oz., worth $45,651,400, a decrease of 514,000 oz. from 1928. Silver production was 61,327,868 oz., worth $32,687,754, an increase of 2,865,361 oz. and a decrease of $1,512,813 in value. Arts and manufactures used 54.5% of the domestic output of new Au and 50.4% of the Ag. Figures for world production are given. AHE (16)

Economic Significance of Special Alloy Steels. H. Batcheller. *Mining & Metallurgy*, Vol. 12, July 1931, pages 312-318.

An economic discussion of the steel industry in general, methods of merchandizing, suggestions for improving conditions, research work and alloyed steels and treating processes for refining and future possibilities. Ha (16)

Building Industry Attains Leadership in 1930 as Consumer of Finished Rolled Steel. *Steel*, Vol. 88, Jan. 1, 1931, pages 248-251.

Gives short discussion of steel demand in 1930 with series of charts and tables showing percentages of annual steel output utilized by the 5 main groups of consumers; building industry, railroads, automotive industry, oil, gas and water industries, and exports for the years 1922 to 1930. A table of steel ingot production shows the tonnages consumed by each of the above groups. Two comprehensive tables give the percentages and the actual gross tons of each type of finished steel product consumed by each group of users. JN (16)

Society for Electrochemical Industry of Norway. (Det Norske A/S for Electrokemisk Industri). *Journal du Four Electrique*, Vol. 40, June 1931, pages 212-214.
This company occupies the predominant position among Norwegian organizations covering the whole field of activities from ore prospecting to the manufacture of chemicals. Just recently the company developed a satisfactory process for production of steel directly from ores in an electric furnace. JDG (16)

Ferro-alloy Trade in France in 1930 (Le marché francais des ferroalliages en 1930). *Journal du Four Electrique*, Vol. 40, Feb. 1931, pages 49-50.
A brief survey of the amounts of ferro alloy consumed in 1930 and the price variations of Fe-Si, Si-Mn, Fe-Mn and ferro-chromes. JDG (16)

Per Capita Steel Use Declines; United States Still Leads. *Steel*, Vol. 88, Jan. 1, 1931, page 270.
The consumption of steel in the U. S. in 1930 was 731 lbs. per capita, a decrease of 27% from 1929. In Belgium-Luxemburg, it was 581 lbs., a decrease of 38%. England consumed 356 lbs. per capita, a loss of 39%; and Germany used 301 lbs., a decrease of 31%. France, however, lost but 1 lb. per capita, using 298 lbs. per capita in 1930 as against 299 lbs. in 1929. JN (16)

Platinum is Surprisingly Cheap. *Journal Society Chemical Industry*, Japan, Vol. 34, June 1931, page 181B.
The price of Pt which recently broke to the level of 7 yen momme (3.75 g.) has collapsed again to a point as low as 6.50 yen, or only 1/10 of 64 yen/momme in 1918. Japan is importing about 11 kg. of Pt/mo. ½ of which is used for technical purposes, the other half for ornaments. MAB (16)

Uniform Cost Methods for Steel and Alloy Foundries. *Steel Founder*, Vol. 2, Apr. 1931, pages 12-13.
The Steel Founders Society of America has worked out a uniform cost sheet which it advocates for general use. Ha. (16)

New Worlds for Steel to Conquer. *Steel*, Vol. 88, Jan. 1, 1931, pages 245-247.
New ideas in architecture show a tendency for exposing the steel framework of buildings. This is seen in a few hospital and church structures in Europe and, to its fullest extent, in the new building of the Worcester Pressed Steel Co. A new building of the A. O. Smith Corp. uses steel plate floors, movable steel partitions, steel wall columns, steel grid flooring and steel plate floor base. The development of steel frame homes of moderate cost, with interior furnishings, sashes, ventilating panels and kitchen and bathroom fittings all of steel, offers a future market for steel products. The use of steel for farm buildings will also create a demand. A large future outlet for steel appears to be in the construction of pipe lines of electrically welded pipe for oil, natural gas, gasoline and, possibly, powdered coal. Much steel will be required, also, for constructing elevated thoroughfares for motor traffic in congested city districts. JN (16)

Steel Plant Expansion Continues Despite Reduction in Earnings. *Steel*, Vol. 88 Jan. 1, 1931, pages 295-297.
In spite of the depression, many millions of dollars were expended in 1930 for steel plant and rolling mill expansion. This is seen in the construction of by-product coke ovens, basic open hearth furnaces, Bessemer converters, rolling mills for producing large diameter electric welded pipe, and plate strip mills. Stacks, blast-furnaces, hot blast stoves and regenerative furnaces were redesigned and enlarged. Improvements were made in sintering plants, in the molding and cooling of pig-iron, in the wider use of natural gas, and in the installation of large type turbo-blowers and combustion control equipment. JN (16)

Production of Iron and Steel in Canada, June, 1931. *Iron & Steel of Canada*, Vol. 14, July, 1931, page 113.
A statement of the production of pig iron, ferro-alloys, steel ingots and castings, and prices in Canada during June 1931. OWE (16)

Production of Iron and Steel in Canada, May, 1931. *Iron & Steel of Canada*, Vol. 14, June 1931, page 97.
A statement of the production of pig iron, ferro-alloys, steel ingots and castings, and prices in Canada during May 1931. OWE (16)

The United States Iron Industry in 1930. *Iron & Steel of Canada*, Vol. 14, May, 1931, page 86.
Abstracts from publications of the U. S. Bureau of Mines, Department of Commerce, covering the year 1930 in the iron and steel industry of the United States.

Production of Iron and Steel in Canada, April, 1931. *Iron & Steel of Canada*, Vol. 14, May, 1931, page 83.
A statement of the production of pig iron, ferro-alloys, steel ingots, and castings, and prices in Canada during Apr. 1931. OWE (16)

General Contraction in World Production of Iron & Steel for 1930. *Iron & Steel of Canada*, Vol. 14, Mar. 1931, page 50.
A brief article accompanied by tables giving details of the decline in world production of iron and steel during 1930 and referring particularly to the variation in production in Great Britain and to the effect upon the market of the East Indian tariff on galvanized sheet. OWE (16)

World Steel Production in Spectacular Drop. *Steel*, Vol. 88, Jan. 1, 1931, pages 266-267.
The year 1930 saw a tremendous drop in the world's iron and steel production. Steel output decreased 19% and pig iron 17.4%. In Germany, steel production fell off 27.5%; in Great Britain 21.2%; in Belgium. 17%; while in France, steel production decreased only 3.4%. The U. S. production fell off from 47.25% of the world's total to 44%. Tables are given showing the production of steel and pig iron in each country from 1913 to 1930. JN (16)

Present Position of the Iron and Steel Industry, *Engineer*, Vol. 151, May 29, 1931, page 606.
From memorandum issued by the National Federation of Iron and Steel Manufacturers. Comments on measures recommended for improving the iron and steel industry such as relief from excessive taxation, protection of the home market, stabilization of world prices and market conditions, and the use of tariffs for obtaining entry to markets now barred by tariffs. LFM (16)

PLANTS & LABORATORIES (17)

Christiania Steel and Rolling Mills (Christiana Spigerwerk Staal og Valseverker). *Journal du Four Electrique*, Vol. 40, June 1931, pages 236-237.
The present works, with the capacity of 40,000 tons per annum, were the results of absorption of the smaller concerns by the original organization founded in 1853. Beside the usual steel mill equipment, it has a 6000 kwh. furnace for direct production of steel from ore which was installed in 1922-1925 and solves the problem economically. Its subsidiary, Norsk Valsewerk at Bergen, produces almost the total requirement of Norway for tin plate. JDG (17)

A New Copper and Brass Rolling Mill in India. *Metal Industry*, London, Vol. 38, May 15, 1931, pages 497-498.
A description of a rolling mill with a capacity of 50 tons of Cu/wk., erected by the Krupp Works. PRK (17)

Norwegian Zinc Company, Ltd. (Det Norske Zinkkompani A/S). *Journal du Four Electrique*, Vol. 40, June 1931, pages 230-231.
The largest European electrolytic zinc plant with the capacity of 40,000 tons a year uses Anaconda type installation. General description is given. JDG (17)

Metallurgical Investigations at Bell Laboratories. *Metal Progress*, Vol. 19, May 1931, pages 33-38.
Notes on the problems and equipment in use at the Bell Laboratories for Metallurgical Investigations. WLC (17)

Steel Plant Built at the Door of a Great Market. *Iron Age*, Vol. 126, Nov. 27, 1930, pages 1606-1610, 1665.
Describes the plant of the Great Lakes Steel Corporation with an annual capacity of over 500,000 tons. Its products will consist of billets, sheet bars, forging bars, strip steel, automobile spring steel, rim sections, bumper steel, window-sash sections, concrete bars and small angles and channels. Approximate cost is about $25,000,000. Plant units are laid out for straight-line production. Future extensions can be made with minimum interference with operations. VSP (17)

Norwegian Nitrides Corporation (Det Norske Nitridaktieselskap). *Journal du Four Electrique*, Vol. 40, June 1931, pages 224-226.
Though originally intended for manufacture of nitrides, the plants of the company never manufactured them. Metallic Al is the only product. 2 plants at Eydehavn and Tyssedal are in operation at the present, under control of British and American Aluminum Companies and Compagnie des Produits Chimiques d'Alais. JDG (17)

The Sand-Spun Pipe Foundry of the Staveley Coal and Iron Company, Limited. *Foundry Trade Journal*, Vol. 45, July 30, 1931, pages 71-73; Aug. 6 1931, pages 83-85.
A detailed description of the sand-spun pipe foundry of the second largest manufacturer of cast iron pipes in the United Kingdom. This factory is designed for an annual output of 80,000 long tons of pipes from 4 in. to 12 in., inclusive, nominal diameters, of 16-foot laying length. The article is accompanied by 12 photographs and 1 diagram, showing the general lay-out of the plant. The Company holds the sole patent rights for Great Britain from the Sand-Spun Corporation. OWE (17)

Meeting Steel Mill Problems at Canadian Plants. *Canadian Chemistry & Metallurgy*, Vol. 15, July 1931, pages 195-197.
Special reference to specifications and the plant of the Algoma Steel Corp. at Sault Ste. Marie, Ontario, seems to reflect the Canadian industry as a whole. WHL (17)

Spring Production for Railway Rolling Stock. *Metallurgia*, Vol. 3, Apr. 1931, pages 199-203.
Describes equipment and methods used by Great Western Railway Co. in manufacturing both laminated and coiled springs. C steels are used for both types. JLG (17)

Expected Activity of New Aeronautical Laboratory. *Journal Society Chemical Industry*, Japan, Vol. 34, June 1931, pages 179-180B.
Reviews what is supposed to be the world's most perfect laboratory of its kind, the Aeronautical Research Institute of Tokyo Imperial University at Komaba, officially opened May 11, 1931. It has space for specialized research in aeronautical physics, chemistry, metallurgy, material, motor, and psychology for aviator. It has a large wind tunnel, a library and central workshop. MAB (17)

The Aluminum Alloy Rolling Mills at Chippis. *Journal Institute of Metals*, Vol. 47, June, 1931, page 5.
Slabs of 100-1000 kg. in weight are rolled down on a 3-high mill with 700/250/700 x 1700 mm. rolls. They then go through a 3-high hot mill of 900/450/900 x 3300 mm. for the production of heavy structural plates or through a 3-high strip mill for sheets of smaller sizes up to 1m. wide. All furnaces are electrically operated with one exception and consume 1500 kw. Other equipment is briefly mentioned. Ha. (17)

Pressed Steel Sleeper Plant at the Glengarnock Works of Colvilles, Ltd. *Iron & Coal Trades Review*, Vol. 123, Nov. 20, 1931, pages 785-787.
A full description of the plant for making railroad ties from bar to finished product. The presses develop 220 tons each. The sleeper-bar heating furnace has a normal output of 15-20 tons of bars/hr. Ha. (17)

Gary Mill Designed for 25,000 Tons a Month of 26-In Strip. *Iron Age*. Vol. 126, Aug. 21, 1930, pages 488-490.
Describes the 28-in. strip mill of the Illinois Steel Co. at Gary, Ind. Mill which comprises 7 two-high stands of rolls 24 in. in diameter, 6 two-high stands of 28-in. rolls and 2 sets of vertical edging rolls, all of which are motor driven. Produces strip steel up to 26 in. in width at rate of 25,000 tons/month. VSP (17)

Stavanger Electric Steel Company (Stavanger electrostaalverk A S). *Journal du Four Electrique*, Vol. 40, June 1931, pages 218-219.
This plant organized in 1910 possesses a completely equipped steel works with the annual capacity of 6000 tons of common alloy and stainless steels. An exceptional quality of the finished product can be obtained here because the original ores which are worked by a duplex process contain 0.06% V and 2% Ti beneficially affecting the quality of steel. JDG (17)

Heat-Treating Pipe Couplings to Withstand High Pressures. *Fuels & Furnaces,* Vol. 9, Jan., 1931, pages 55-58.

The plant equipment for heating, reheating, temperature control and the burner equipment of the Dresser Manufacturing Co., Bradford, Pa., is described and illustrated. Ha. (17)

The Laboratories of the Iron and Foundry Institute of the Academy of Mines Clausthal (Die Laboratoriumsanlagen des Instituts für Eisenhütten—und Giessereiwesen der Bergakademie Clausthal). *Giesserei mit Giesserei-Zeitung,* Vol. 18, Oct. 30, 1931, pages 848-850.

A description of the melting and pouring rooms, the equipment of the metallurgical, heat and materials testing laboratories. The practical work of students is described. Ha. (17)

Increases Production with Handling Equipment. *Foundry,* Vol. 59, Oct. 15, 1931, pages 40-41.

The layout and equipment of the foundry of the American Seating Co., Grand Rapids, Mich., is described. Ha. (17)

Non-Ferrous Metals Research. *Electrical Review,* Vol. 108, June 12, 1931, pages 994.

Description of new administrative buildings and central research and development laboratories in London. Ha (17)

Heat Treating Equipment in a Modernized Plant. *American Machinist,* Vol. 75, Oct. 22, 1931, pages 635-637.

Description of the plant of R. Hoe & Co. Ha. (17)

Specializes in Stoves for Seventy-Six Years. PAT DWYER. *Foundry,* Vol. 59, Sept. 15, 1931, pages 26-28, 40.

Describes the plant of the Pratt Manufacturing Co., Watertown, Mass., established in 1855. VSP (17)

Electrification of Merchant Mills. E. J. POOLE & O. C. CALLOW. *Freyn Design,* No. 9, Oct., 1931, pages 1-4.

A description of a recently electrified 16 in. guide mill, a 12 in. bar mill, a 10 in. guide mill and a 10 in. bar mill of the Carpenter Steel Co. in Reading, Pa. Ha (17)

Tool Heat Treating at Schenectady. R. H. MITCHELL. *American Machinist,* Vol. 75, July 23, 1931, page 163.

Brief description of the layout of the plant and arrangement of equipment. Ha. (17)

The Newport News Shipyard; How Welding is Revolutionizing Ship Construction. JAMES W. OWENS. *Welding,* Vol. 2, Nov. 1931, pages 734-736.

Notes the great extent to which welding is now used. Ha. (17)

The Development of the Herminenhütte in Laband, Upper Silesia, with Special Reference to the New Constructions and Reconstructions After the Year 1926 (Die Entwicklung der Herminenhütte in Laband, O.-S., unter besonderer Berücksichtigung der Neu- und Umbauten nach dem Jahre 1926). C. NETTER. *Stahl und Eisen,* Vol. 51, October 22, 1931, pages 1306-1313.

Report 89 of the Rolling Mill Committee of the Verein deutscher Eisenhüttenleute. Whereas a previous paper dealt with a description of this Upper Silesian steel plant before the modernization (see *Stahl und Eisen,* Vol. 51, Sept. 24, pages 1189-1192) the present paper gives a detailed account of the changes that have been effected by the reconstruction of the rolling mills since the year 1926. After dealing with the reasons for the modernization, the new rolling mills are individually described. The production capacity could be increased from 6800 tons of hoops and bars to a monthly production of 3000 tons of hoops and 9000 tons of bars with 2 shifts/day. The production of the mill is not large in comparison with the large mills in Western Germany, but it is nevertheless remarkable due to the large number of various shapes which are rolled during a shift. GN (17)

Melts Bronze in Crucibles. FRANK MCKLVEEN & R. H. STONE. *Foundry,* Vol. 59, Sept. 15, 1931, pages 38-40.

Describes operation of the Robertshaw Thermostat Co., Youngwood, Pa. The company produces castings in 85-5-5-5 metal and, as castings are Cr plated, the requirements are severe. The melting equipment consists of 5 tilting type furnaces made by Campbell-Hausfield Co., each taking a standard No. 125 Steel-Harvey graphite crucible. Unusual economies in fuel consumption have been achieved. Outlines daily practice. Lining of combustion chamber is rammed in place using a silicon-carbide refractory. Cost of melting can be taken either as ready to pour out of the furnace or cost of metal delivered to the molds. VSP (17)

Indirect Heat Utilized in Dual Purpose Oven. J. B. NEALEY. *Foundry,* Vol. 59, May 1, 1931, pages 70-71.

Describes the oven installation at the plant of Hansell-Elcock Co., Chicago, which produces castings ranging from a few oz. to 30 tons. VSP (17)

Facilitates Production of Large Steel Castings. E. C. KREUTZBERG. *Foundry,* Vol. 59, May 1, 1931, pages 44-49; *Steel,* Vol. 88, May 14, 1931, pages 35-37, 52.

Describes the new plant of the General Steel Castings Corporation, Eddystone, Pa. Castings for locomotives and railroad cars are to be the chief products. The present capacity of the plant is between 6000 and 7000 tons of castings/mo. Steel is melted in 3 50-ton open hearth furnaces. Patterns and core boxes are handled collectively. Continuous core oven 230 ft. long is arranged in 5 tiers. It is heated by 4 oil fuel units. Ha+VSP (17)

The New Montreal Foundry of the Canadian National Railway Company. *Foundry Trade Journal,* Vol. 45, Aug. 13, 1931, pages 99-101; *Canadian Foundryman,* Vol. 22, May, 1931, pages 7-11.

A description of the gray iron foundry at the Point St. Charles (Montreal) shops of the C.N.R., which is the fourth unit to be completed under a rehabilitation and modernization program. The article is accompanied by 10 photographs. OWE (17)

Electrical Equipment for Gulf States Steel Universal Plate Mill. R. H. WRIGHT. *Blast Furnace & Steel Plant,* Vol. 18, Nov. 1930, pages 1710-1711.

A direct current reversing motor of 4000 h.p. and 80/160 r.p.m., 80 volts drives the 32 in. 3-high universal mill; it is supplied by 3200 kw. fly-wheel motor-generator set. The electrical installation for the auxiliaries is described in detail. Ha. (17)

MISCELLANEOUS (20)

Wire Cable Compacted by Stretching it Beyond Working Load. *Iron Age,* Vol. 125, June 12, 1930, pages 1748-1749.

In order to equalize irregularities and ununiformities of manufacture in wire cables, they are pre-stressed beyond the working load. The method of doing this in the works of J. A. Roebling is described in detail and examples of a few bridges where the suspension cables were treated in this manner are given. Ha. (20)

Calculation and Administration of Spare Parts in Steel Mills (Verrechnung und Verwaltung von Ersatzteilen auf Hüttenwerken). *Archiv für Eisenhüttenwesen,* Vol. 5, Aug. 1931, pages 127-128.

Report 51 of the Committee on Plant Efficiency of the Verein deutscher Eisenhüttenleute. Brief résumé and discussion of papers on the above subject at a meeting of the mentioned committee. GN (20)

Intermediary Compounds Formed during the Catalytic Synthesis of Ammonia. Detection of a "Surface Nitride" Consisting of Tungsten and Nitrogen (Zur Kenntnis der Zwischenverbindungen bei der katalytischen Ammoniaksynthese. Auffindung der Bildung eines "Oberflächen-Nitrids" aus Wolfram und Stickstoff). G. MESSNER & W. FRANKENBURGER (I. G. Farbenindustrie). Zeitschrift für physikalische Chemie, Bodenstein Festband, 1931, pages 593-607.

The heterogeneous systems (1) W-NH_3, (2) W-H_2, (3) W-N_2 and (4) $W(N)_x$-H_2 are investigated and effects observed indicating 2 modes of union of gases at the metallic surface, i.e., in the case of (1) and (2) and absorptive and in the systems (3) and (4) a chemical binding. Conclusions drawn are (a) NH_3 and H_2 are normally absorbed by pure W powder; (b) a phenomenon never identified before (the molecular binding of N by metallic W) was detected and proved to be a chemical reaction by the determination of the temperature dependence, course of velocity and non-reversibility; (c) the nitride discussed slowly absorbs H between 20° and 200° C. and probably forms a hydrogenation product with the N_2 previously absorbed; (d) the reactions given under (b) and (c) are considered as partial processes closely connected with the catalytic synthesis of NH_3 with W as a catalyser. EF (20)

Training Apprentice to Foreman. E. H. BALLARD. *Transactions & Bulletin, American Foundrymen's Association,* Vol. 2, Jan. 1931, pages 767-770.

The author feels that training is more necessary than ever in the foundry, because of keener competition which requires a higher standard to put the foundry on a plane equal to that of other manufacturing departments. CHL (20)

Binary Catalysers on Molybdenum-Base Applied for the Ammonia Synthesis (Ueber binäre Molybdän-Mischkatalysatoren bei der Ammoniaksynthese). A. MITTASCH & E. KEUNECKE (Research Laboratory I. G. Farbinindustrue, Oppau). *Zeitschrift für physikalische Chemie,* Bodenstein Festband, 1931, pages 574-582.

The system Co-Mo and Fe-Mo, as well as mixtures of Mo with Cu, Cr, W and Mn, were investigated as catalysers with reference to the ammonia synthesis. An increase in efficiency could be secured if the components form compounds. This is also true for the systems Ni-Mo, Co-Mo, Fe-Mo, Mn-Mo. The combination Cu-Mo acts merely additively, since the components are indifferent. Formation of solid solutions weakened the catalytic effect of the binary systems W-Mo and Cr-Mo, which do not enter a chemical compound. The formation of a chemical compound does not, however, necessarily result in an activation, as was revealed with the system Mo-S, which disclosed a remarkable, poisonous effect. EF (20)

Cupola Slag is Granulated. M. J. GREGORY. *Foundry,* Vol. 59, June 1, 1931, page 75.

Slag running out against a stream of water over a tank is broken up into pieces of about ¼ in. mesh. Ha. (20)

The Photo-Electric (Bequerel) Effect on Electrodes of Bismuth Oxide (Die Gesetzmässigkeiten des lichtelektrolytischen Effekts (Bequerel-Effekts) an Wismutoxydelektroden). A. COEHN & R. MYKOLAJEWICZ (University of Göttingen). *Zeitschrift für physikalische Chemie,* Bodenstein Festband, 1931, pages 641-655.

Only electrodeposited Bi_2O_4 shows the Bequerel-effect among a large number of metal oxides. The photo-electric reduction of Bi_2O_4 to Bi_2O_3 accounts for the change in electrode potential when the electrode is radiated. A local element between the Bi_2O_4-Bi_2O_3 mixture and the carrier metal exerts an influence, too. Bi_2O_4 is furthermore reduced to Bi_2O_3 due to the light energy absorbed. The oxygen liberated diffuses to the surface where O_2 changes the potential. The quantum yield, however, is of a very small order: 10^{-5}-10^{-4} electric elementary charges per light-quantum. EF (20)

Directions for the Design of Proper Water Chambers for Acetylene High Pressure Apparatus (Richtlinien für den Bau geeigneter Wasservorlagen für Azetylen-Hochdruckapparate). H. FRIEDRICH. *Forschungsarbeiten auf dem Gebiete des Schweissens und Schneidens mittels Sauerstoff und Azetylene,* Series 6, 1931, pages 65-80.

The German rules for acetylene operations require a safety device, usually a water chamber in front of the acetylene developer which acts as protection against back firing of the flame and against the possibility of O entering the acetylene pipes. The different methods and the testing of their efficiency are discussed, described and illustrated. See also *Metals & Alloys,* Vol. 2, Oct. 1931, page 227. Ha. (20)

A New Profile for Spring Plates (Ein neues Federblattprofil). *Krupp'sche Monatshefte,* Vol. 12, Jan. 1931, pages 7-9.

A new profile for spring plates which marks a remarkable progress in the making of springs is described. The new shape offers the advantage of making softer and more durable springs. GN (20)

FOUNDRY PRACTICE & APPLIANCES (22)

Meeting the Demand for Aluminum Castings. *Canadian Foundryman,* Vol. 22, Aug. 1931, pages 7-11.

The characteristics and applications of a number of Al alloys are described and details given of pattern and core design, suitable molding sands and gating requirements in the production of castings from these mixtures. Reference is made to "modification" and heat-treatment processes and to methods of inspection. OWE (22)

Centering Ingot Mold Cores. *Foundry,* Vol. 59, Jan. 1, 1931, page 74.

Description of several methods of centering ingot mold cores as well as the practice in some foundries. Ha (22)

Prevent Losses with Proper Gates and Risers. PAT DWYER. *Foundry,* Vol. 59, Jan. 1, 1931, pages 56-60; Jan. 15, 1931, pages 48-51; Feb. 1, 1931, pages 66-68; Feb. 15, 1931, pages 49-51; Mar. 1, 1931, pages 66-69; Apr. 1, 1931, pages 57-59; May 1, 1931, pages 52-54; June 1, 1931, pages 60-62; June 15, 1931, pages 41-43; July 1, 1931, pages 53-56; July 15, 1931, pages 41-43; Aug. 1, 1931, pages 53-56; Oct. 1, 1931, pages 51-53, 56; Oct. 15, 1931, pages 34-36, 38.

The causes of 50 defective castings were analyzed and found to be due, in the majority (44) of cases, to faulty molding practice. The importance of proper arrangement of patterns and disposition of the gate or gates, their shape, size and positions is noted and illustrated by examples. Interesting results were obtained with a system of small gates and slow pouring. The nomenclature of foundry terms is explained. Ha (22)

Corrugated Pipe Pattern Forms Mold and Core. PAT DWYER. *Foundry,* Vol. 59, June 15, 1931, pages 57-60.

Describes the molding and pouring at the American Castings Co., Birmingham, Ala. Ha (22)

Bronze Pressure Castings Require Exact Practice. J. E. CROWN. *Foundry,* Vol. 59, June 15, 1931, pages 39-40. *Metal Industry,* London, Vol. 39, Aug. 7, 1931, pages 127-128.

The importance of such factors as selection of alloys, design of patterns, method of molding, character of cores and type of heads and gates in the successful production of bronze pressure castings is noted by a description of the practice employed in the U. S. naval gun factory. The analyses of several alloys which are applicable are given. Ha+PRK (22)

Bond Fitting Cores with Cement. PAT DWYER. *Foundry,* Vol. 59, Mar. 1, 1931, pages 77-80.

Melting and molding practice at the plant of the Walworth Co., Boston, is described and illustrated. Ha (22)

Recent Developments in Cast Iron and Foundry Practice in Great Britain. J. G. PEARCE. *Iron & Steel Industry & British Foundryman,* Vol. 4, July 1931, pages 329-332; Aug. 1931, page 377; *Foundry Trade Journal,* Vol. 44, June 25, 1931, pages 436-438; Vol. 45, July 9, 1931, pages 21-24, 27.

Condensed article from the Institute of British Foundrymen. The work at the British Cast Iron Research Association is briefly reviewed. "Balanced blast" cupola is described. Controlled cast iron may, possibly, be produced by completely removing graphite and then inoculating the melt with material calculated to yield fine pearlite and normal graphite. See also *Metals & Alloys,* Vol. 2, Nov. 1931, page 280. CHL+OWE (22)

The Laboratory and the Foundry. R. ARZENS. *Iron & Steel Industry & British Foundryman,* Vol. 4, Aug. 1931, pages 364-370.

General. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 279. CHL (22)

The Best Practice in Casting Bronzes. *Brass World,* Vol. 27, Aug. 1931, pages 181-183.

A report of the Non-Ferrous Committee on recommended practices at the meeting of the American Foundrymen's Association in Chicago, Ill., May 4-7, 1931, is reviewed. Tentative recommended practice for the alloy; Cu 85, Sn 5, Pb 5, Zn 5 are shown. Physical properties for sand casting are tabulated. Recommended practice for manganese bronze and for the alloy containing Cu 80, Sn 10 and Pb 10 is also discussed. WHB (22)

Patternmaking and its Relation to Design and Foundry Practice. MATTHEW RUSSELL. *Canadian Foundryman,* Vol. 22, May 1931, pages 12-14.

An article in which the question of designing castings to compete with welding is dealt with in some detail, and in which methods of designing patterns for various purposes are discussed. The article is accompanied by 13 diagrams. See also *Metals & Alloys,* Vol. 2, Nov. 1931, page 280. OWE (22)

Improvements in Physical Properties in Large Carbon and Alloy Castings. J. D. FENSTERMACHER. *Steel Founder,* Vol. 2, June-July 1931, pages 4-7.

The principles of good alloy steel casting—(1) the production of a metal of predetermined quality, (2) good foundry practice, (3) proper heat treatment—are set forth and several very large castings are illustrated. From 59 heats made by the Columbia Steel Co. of Pittsburgh, the weights of the pieces varied between 40,000 and 64,400 lbs. The ultimate strength was, on the average, 75,800 lbs./in.^{2}; elastic limit, 44,100 lbs./in.^{2}; elongation in 2 in., 30.5%; the reduction in area, 48.5%. Ha (22)

Stainless Steel Castings Need Fine Facing Sands to Obtain Smooth Finish. EDWIN BREMER. *Foundry,* Vol. 59, Feb. 15, 1931, pages 38-42.

The melting and pouring practice of the West Steel Casting Co. for stainless steel castings is described; the standard 18-8 alloy is usually used. The material is produced in the electric furnace; all scrap is employed without any addition of Ni; the bath temperature is raised to 3200° F. as rapidly as possible; and the liquid metal is tapped from the furnace into 2000-lb. bottom-pour ladles. The precautions necessary in melting to obtain the dissociation of C from Cr and to form austenite are described. Ha (22)

Addition of Fluorspar to the Cupola (Addition de spath fluor au cubilot). D. Deuvorst. *Congres International des Mines, de la Métallurgie et de la Géologie appliquée. Section de Métallurgie,* 6th session, Liege, June 1930, pages 785-790. 14 references.

Compares use of 3% limestone on weight of Fe with that of 2% limestone, plus ¾% fluorspar. No difference was found in composition of gas, Fe or slag. More coke was recovered unburnt without spar than with it. The use of spar injures the lining and the fume is harmful to vegetation. See also *Metals & Alloys,* Vol. 2, Dec. 1931, page 321. HWG (22)

Preparation and Distribution of Molding Sands. H. L. McKinnon. *Iron Age,* Vol. 128, July 30, 1931, pages 312-313.

The quality of the work produced and profits secured from operations depend on the proper handling of the 2 activities. A thorough description of methods and apparatus for handling and preparation of sand is given. Ha+VSP (22)

Outlines Methods for Making High-Test Gray Iron in the Shop Making Machine Tool and Jobbing Castings. L. M. Sherwin & T. F. Kiley. *Foundry,* Vol. 59, July 1, 1931, pages 45-48; July 15, 1931, pages 47-49.

Internal shrinkage, sponginess and porosity can be eliminated by the use of low C cast iron. Chills are used sometimes, particularly if the casting has sections less than ¼ in. Methods of control, typical analyses of product and microstructures are discussed. Compares machining strength and other physical properties of a number of mixtures. Using up to 2% Mo, the following results are obtained: (1) the combined C is raised, but not above eutectoid; (2) the transverse strength is increased; (3) Brinell hardness is increased; (4) solid contraction is decreased; (5) pearlite is sorbitized; (6) graphite flakes are made smaller; (7) deflection is increased. Part 2. Main purpose of Ni in castings is to aid machinability. The use of ferrosilicon to 1.25% causes shrink holes. Cr is added to Fe used for high temperatures. Castings of high test Fe offer more resistance to tool penetration but are free from hard spots. Dry sand molding is followed in production of high test Fe to insure sound and good surfaced casting. VSP (22)

Physico-Mechanical Testing of Sands (Analyse physico-mécanique des sablés). Andre Guedras. *Aciers Spéciaux, Métaux et Alliages,* Vol. 6, May 1931, pages 239-242.

Moisture in foundry sand can be determined in 20-25 min. by a new method. To a 100 gm. sample of foundry sand, are added 200 cm.^{3} xylene or toluene. This mixture is heated in a closed vessel to boiling temperature. The water will begin to evaporate first, followed by the xylene. The condensed mixture of the 2 liquids is collected in a graduated cylinder. As these 2 liquids do not mix, they separate into 2 distinct layers, from which the percentage of moisture could be measured. Determination of silica, clay and of the colloidal matter is carried out on the same sample of sand. This analysis requires use of $CaCl_2$ solution of 1.12 specific gravity and alcohol. GTM (22)

Studies on the Filling Frame of Molding Machines. (Studien über den Füllrahmen an Formmaschinen.) A. Rodehueser. *Giesserei-Zeitung und Giesserei,* Vol. 18, Feb. 6, 1931, pages 116-124.

To obtain a certain uniform denseness in molding boxes, the molding box must have a definite height which can either be calculated or be determined graphically from diagrams which are developed. Differences in the denseness, due to the shape of the pattern, can be equalized by calculable differences in the height of the molding sand or in the dimension of the pressure plates. Certain axioms are developed which, if observed, reduce the molding time and guarantee a more uniform product. In this manner the economy of pressure molding machines is increased. Several examples illustrate the procedures. Ha (22)

The Structure of the Compressed Molding Sand and Its Importance in the Testing of Compressed Molding Sand. (Der Aufbau des verdichteten Formsandes und seine Bedeutung für die Formsandprüfung.) W. Reitmeister. *Die Giesserei mit Giesserei-Zeitung,* Vol. 18, Mar. 1931, pages 257-260.

First the conception of "structure" of the sand is defined as the volumetric ratio of the constituents of the sand to the volume of the grain of condensed sand. By considering humidity, grain and grain size, this factor is developed and tested for several kinds of sand and represented in diagrams. In this way the porosity and volume of pores can be exactly defined. Ha (22)

The Moore Hot-Blast Cupola. Jas. T. MacKenzie. *Transactions & Bulletin American Foundrymen's Association,* Vol. 2, Aug. 1931, pages 197-204; *Foundry Trade Journal,* Vol. 45, Sept. 10, 1931, pages 165-166.

Description of the installation and operating records showing variations in the temperature and amounts of coke consumed with the hot-blast cupola is given. Comparisons are made with the hot-blast and cold-blast cupola processes. OWE+CHL (22)

A Note Upon the National Position of Metallurgical Knowledge and Efficiency in Ordinary Iron Foundries. Horace J. Young. *Foundry Trade Journal,* Vol. 45, Dec. 10, 1931, pages 366-368.

A discussion of the characteristics of the average foundry, followed by suggestions as to the economies and advantages of metallurgical standardization and control. Points out that expensive raw materials are usually unnecessary in foundry practice but that scientific mixing of the ingredients is essential. Some discussion of the solution of graphite in molten pig iron and of pig-iron composition closes the paper. OWE (22)

Wrought-Iron Core Support in Gray Iron (Flusseisenkernstütze im Grauguss). M. von Schwarz & H. Schropp. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Sept. 11, 1931, pages 725-731.

A series of micrographs show the structure of a core support which has become an integral part of the surrounding cast iron. On the basis of these micrographs, the phenomenon is discussed in detail. Ha (22)

FURNACES & FUELS (23)

Industrial Gas and Electric Furnaces. E. Gossow. *Engineering Progress,* Vol. 12, Oct. 1931, pages 217-222.

A general survey of operating characteristics and classification of industrial furnaces. The furnace atmosphere, fuel gases and burners are discussed and a few large installations are described. Ha (23)

The Problem of Melting Furnaces for the Iron Foundry (Le problème du four de fusion dans la fonderie de fer). T. Geilenkirchen. *Congrès International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 791-800. 12 figures.

Describes cupolas, reverberatories fired with different fuels, recuperative furnaces, the Brackelsberg powdered coal furnace and electric furnaces. For temperatures required by special irons, outside the range of the cupola, the Brackelsberg furnace is considered most promising for European conditions. The electric furnace is considered less suitable for average European conditions than for American ones. In discussion (page 851), Ronceray stated that the Brackelsberg furnace was not an improvement, and would not have a permanent place in the foundry, but Thomas and others defended it. HWG (23)

High Frequency Steel Furnaces. D. F. Campbell, *Chemical Age,* London, Vol. 23, Metallurgical Section, Oct. 4, 1930, pages 19-20.

Iron & Steel Institute paper, Sept. 16, 1930, at Czechoslovakia. See *Metals & Alloys* Vol. 2, Jan. 1931, page 16. VVK (23)

Some Experimental Data on the Influence of Dry and Wet Cleaning on Coke Properties and on Gas and By-Product Yields. A. C. Fieldner. *Report of Investigations* 3114, *United States Bureau of Mines,* May 1931, 9 pages; *Fuel,* Vol. 10, July 1931, pages 320-327.

Within the moisture limits of the coals tested (4.2% maximum moisture) there was no difference observed in the effect of dry or wet cleaning on the coke, gas, or by-products. In the plant tests, the nut and range size of coke showed from 1.3 to 2.9% more of ash than the stove size from the screened lump coal, whereas the washed coal showed an increase of 0.2 to 0.8%, indicating that the free impurities tend to segregate in the smaller sizes. The heating value and the cubic-foot yield of gas from the washed coal is greater than from the unwashed, and in slightly greater proportion than that due to the difference in the diluents, ash and moisture. The yield of tar and light oil is higher from washed coal than from unwashed, even after allowing for the difference in ash and moisture. A high percentage of mineral matter in the coal appears to promote cracking of tar. The yields of ammonium sulphate in the iron-retort tests were materially less from the washed coal containing 4% of moisture than from the unwashed coal containing 1.2% of moisture. But in the laboratory silica-tube tests the yields were slightly higher from the washed coal. It is believed that the silica-tube results for ammonia are more indicative of the practical results because of the known catalytic effect of hot iron on the decomposition of ammonia. These conclusions apply to washed coal containing not over 4% of moisture. Further experiments should be made with increasing percentages of moisture to determine its effect, and likewise with different sizes and kinds of impurities with reference to their effect on coke structure. Changes in size may reverse the effect, as in the case of fusain. Large pieces of fusain mixed with coal weaken the coke, whereas finely divided fusain mixed with strongly fusing coal improves the physical properties of the coke. WAT (23)

An Electric Reflection Furnace (Ein elektrischer Reflexionsofen). C. Benedicks & J. Härden (Metallografiska Institutet Stockholm). *Zeitschrift für technische Physik,* Vol. 12, Apr. 1931, pages 234-243.

The authors designed an electric reflection furnace mainly consisting of an elliptical mirror of Cu and an electric arc and claim the following advantages: (1) non-conducting materials are melted without being in touch with foreign matter (crucible walls); (2) extremely short time required for running up to the melting point; (3) temperatures higher than 2000° C. (about 3620° F.) are easily attained; (4) utilization of the equipment for melting in vacuo. Experiments were carried out with the object of determining the efficiency of the new furnace. The best result yielded 25% of the input (energy required for the electric arc); presumably the Cu-mirror was in a highly polished state. Data of the water-cooled Cu-mirror: 42 cm. diameter, 14.5 cm. focal distance, Cu sheet of 1.5 mm. thickness. See also *Metals & Alloys,* Vol. 2, Dec. 1931, page 322. EF (23)

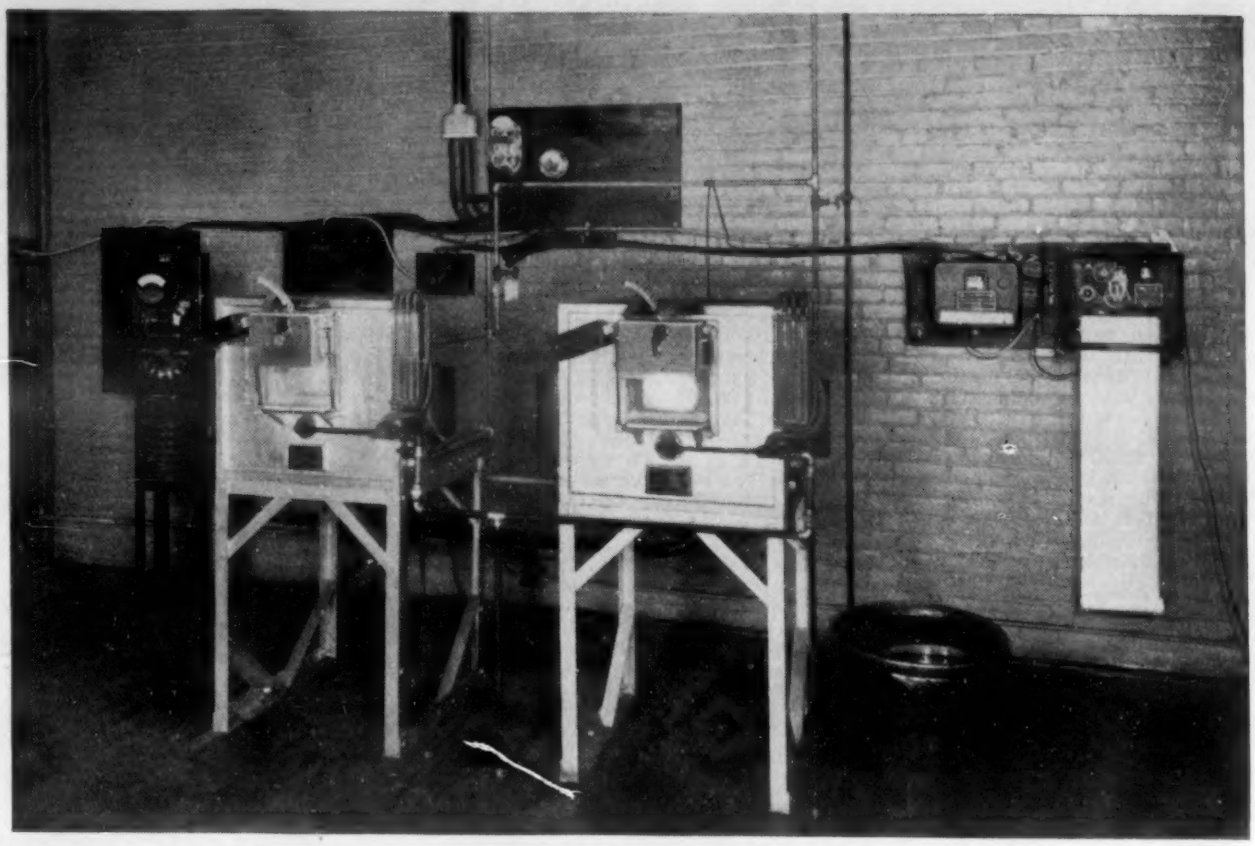
Produces Special Purpose Iron in Rotary Furnace. *Foundry,* Vol. 59, July 1, 1931, pages 49-52.

Rotary furnace fired with powdered fuel is developed in Germany. It is designed for the production of high grade iron castings and alloy gray iron castings containing Ni, Cr, V, Mo, Cu, Mn, etc. Also used for the production of malleable iron. Characteristic of the furnace is the high grade of Fe produced. Tabulates results of tests made on standard arbitration bars known as the A.S.T.M. specification A49-29. The furnace is designed as a flexible unit. VSP (23)

Development in By-Product Coke Production. A. C. Fieldner (U. S. Bureau of Mines). *Iron Age,* Vol. 128, July 16, 1931, pages 165, 207.

Abstract of a paper read before the American Society of Mechanical Engineers at Chicago. Early manufacture of blast furnace coke in beehive ovens was an enormous waste. In 1929, 90% of the production was in by-product ovens. By-product ovens have not only displaced beehive ovens in producing metallurgical coke, but they are supplying base-load gas in conjunction with coke for domestic fuel. Further developments may be checked in certain localities served by long distance natural gas pipe lines. S recovery purification process promises to give new by-product S adapted to fungicidal and agricultural purposes. Phenol is being recovered in salable form. VSP (23)

In These Two "Globar" Equipped Furnaces Some Heat-Treating History Was Made



THE completed report on a series of furnace demonstrations made some months ago in Cleveland goes far indeed in establishing more outstanding records for Globar Brand Elements, the Hayes Furnace and treating by electric heat.

Sixty-six practical demonstrations were made—metallurgists, heat treaters, plant executives—steel men—came either to run or supervise the operation of these furnaces.

They brought their own tools—everything from the most delicate cutters and reamers to drills, heavy forming tools and dies.

They did their own heat-treating—drew their own conclusions—in other words it was a practical demonstration.

And the results?

Well, in many instances, they were astonishingly successful.

The "Globar" equipped Hayes Furnaces with atmospheric control, heat-treated high speed saws without scale—without warpage—high speed threading dies came out perfectly hardened—chasers and dies clean, unscaled, with a Rockwell as high as 65–67.

They took out spline and gear cutters with a Rockwell hardness of 66–67 with no dimensional change. And so on through the whole series—practically every demonstration test beyond the expectations of ordinary heat-treating practice.

Through it all, Globar Brand Elements were the source of dependable, accurately controlled uniform heat, maintaining the necessary high temperatures—helping to make possible this outstanding record.

Factors Influencing the Design of Normalizing Furnaces. E. E. Griffiths. *Heat Treating & Forging,* Vol. 17, Feb. 1931, pages 173-176; *Sheet Metal Industries,* Vol. 4, Jan. 1931, pages 759-765.

General requirements for all normalizing furnaces include: (1) they should be capable of heating the sheets above their A_3-temperature; (2) the rate of heating and cooling should be controllable; (3) each individual sheet of any particular gage and specification should be treated alike. The surface of the sheets must not be damaged by scratching, pitting or oxidation. The sheet should be delivered from the furnace as flat as possible. The principal types of present normalizing furnaces are the rotating disk conveyor, the walking-beam conveyor, the continuous conveyor. The design, heat insulation, recuperation, mechanical upkeep and operating costs are discussed and curves showing the absorption of heat by sheets and furnace walls and the losses through the latter are given. See also *Metals & Alloys,* Vol. 2, Mar. 1931, page 75. AWM+Ha (23)

A New Experiment to Demonstrate the "Pinch" Effect (Ein neuer Versuch zur Demonstration des "Pinch"-Effektes). E. Blaich. *Elektrotechnische Maschinenbau,* Vol. 48, Dec. 7, 1930, pages 1083-1085.

An experiment is described in which a fiber cylinder filled with Hg was used. The Hg represented the molten metal in the induction furnace. When an alternating current of sufficient strength was sent through the metal, forces were generated which made the metal rise or fall in the communicating U-tubes and a complete circulation could be obtained. This is due to a contraction or pinching effect at certain points and is accompanied by violent local currents in the molten metal. Electromagnetic forces are the cause of this phenomenon. The theory for the calculation of the forces created is briefly developed. Ha (23)

New Economies from an Old Furnace. G. M. Bayne (Canadian Westinghouse Co.). *Electric Journal,* Vol. 28, Nov. 1931, page 640.

The conversion of porcelain enamelling furnace from oil to electric operation has shown surprising economies in at least one recent case. A Canadian manufacturer found more even distribution and closer control of heat, resulting in a 75% reduction in rejects, less warpage and a better and more glossy surface on the enamelled parts. Other advantages include: a thinner coat of enamel, and clipping is reduced. No repairs have been necessary in 1 year's operation. WHB (23)

Testing and Rating of Fuel-Fired Industrial Furnaces. Part XVIII. W. C. Buell, Jr. *Fuels & Furnaces,* Vol. 8, Nov. 1930, pages 1495-1498; Dec. 1930, pages 1645-1648, 1659.

It is shown how a heat balance is made up of the whole furnace and its parts. Ha (23)

Industrial Heating. W. E. Swale. *Electrical Review,* Vol. 108, June 19, 1931, pages 1051-1052.

The supply of electric power to heating and furnace installations in its reaction on the power supply and rates charged for it are discussed. A table gives load factors and operating features of furnaces and ovens of various industrial undertakings. Ha (23)

Successful Open-Hearth Furnace Operation with Coke Oven Gas. A. J. Ebner. *Freyn Design,* No. 9, Oct. 1931, pages 5-7.

A group of 9 furnaces in the Hoesch Steel Works, Dortmund, Germany, consisting of 5 30-ton units, 3 of 100 tons and one 150-ton unit (the last of the tilting type) use from 9300 to 10,400 ft.^{3} of coke oven gas/gross ton of steel produced; the gas has a heat value of 527 B.t.u./ft.^{3}. These figures cover the entire campaign including all gas used in the furnaces. The charges consist of 75% scrap and 25% iron, of which approximately 85% of the heats use hot metal and the remainder, cold pig. Water cooling of doors, frames and ports requires an average of 1580 gals./ton of steel. The 100-ton furnaces make 3.3 heats a day, or 15.5 tons/hr. The hearth load is 68 lbs./ft.^{2}/hr. After a period of 1200 heats, the checker bricks must be renewed. A drawing of the construction of a furnace is reproduced. Ha (23)

Some Future Fuel Problems in Metallurgical Practice. H. C. Armstrong. Paper before *Third International Conference on Bituminous Coal* in Pittsburgh, Pa.

The author discusses, from the British viewpoint, the problem of coal and its eventual replacement by another fuel. The exhaustion of the better qualities of coal with low S will compel either the use of a method to eliminate the deleterious effect of the contact of steel with S gases (in the blast furnace and Siemens melting furnaces) or a changing over to other fuels and, perhaps, other furnace designs. The economical factor will be of determining influence. Ha (23)

Automatic Control of Blast Furnaces Gains Favor. *Steel,* Vol. 88, Jan. 1, 1931, pages 291-294.

The achievements of the blast-furnace industry in 1930 include decreased flue dust losses and fuel consumption, wider use of blast furnace and coke oven gas mixtures for heating open-hearth furnaces and coke ovens, extensive adoption of hot blast stoves, construction of stationary towers and gas washing equipment and an increase in the number of sintering plants for treating ores high in moisture, S and percentage of fines. A great advance was the installation of turbo-blowers up to 110,000 ft.^{3} capacity with complete remote, automatic volume indicators and volume control. Complete automatic control and operation of the furnace stock house was accomplished, including recorders to mark the operation of top, skips, stock line and bin gates. The full automatic charging of coke by weight and by volume was also achieved. The tendency to increase the hearth diameter of the blast-furnace without materially increasing the stock line diameter has resulted in less economical practice. JN (23)

Practical Applications of Heat in Metallurgy. H. Dobbin. *Iron Age,* Vol. 128, July 16, 1931, pages 180-181, 208.

A general discussion of combustion problems, reducing atmospheres, etc. The author's aim is to show the means by which, with proper equipment and arrangement, savings may frequently be realized. See *Metals & Alloys,* Vol. 2, Sept. 1931, page 189. Ha (23)

Controlled Atmospheric Steel-Hardening Furnaces. *Industrial Chemist,* Vol. 7, June 1931, pages 256-257.

A brief description of a new-type Birlec furnace designed to operate at temperatures up to 1350° C. The heating elements are "Globars" located at the sides of the furnace and extending from front to back. RAW (23)

Electric Heating Furnaces. *Metallurgia,* Vol. 4, May 1931, pages 1-3.

A description of some of the large heat-treating furnaces made by the Hevi Duty Electric Co. JLG (23)

Metal Processing with Electric Furnaces. *Brass World,* Vol. 27, Oct. 1931, page 223.

The Process Engineering & Equipment Corp., Attleboro, Mass., manufactures an electric furnace applicable to various processes such as bright annealing in one operation. The furnace known as "Preeco" employs a special atmosphere for bright annealing such products as strips, blanks, stampings and wire of such metals as brass, steel, sterling, Cu, Ni-silver, phosphor-bronze and other alloys. Cu-brazing may be carried out without drilling, tapping, riveting or welding to produce tight joints in a wide variety of metals. Bright Ag soldering is accomplished in this furnace. The furnace is illustrated. WHB (23)

Industrial Resistance Electric Furnaces (Le four electrique a resistance a usage industriel). *Journal du Four Electrique,* Vol. 40, July 1931, pages 281-287.

A general survey of the possibilities of electric resistance furnaces for industrial applications and a brief description of muffle furnaces, salt bath furnaces, high temperature furnaces both with liquid resistor and with silite elements manufactured by Siemens Co. JDG (23)

An Inexpensive Electric Furnace. *Electrical Review,* Vol. 108, June 5, 1931, page 944.

Complete winding and building data for an electric resistance furnace for temperatures up to 900° or 1000° C., at 110 V. and 60 amp. The furnace can operate under vacuum. Ha (23)

Perfect Electric Galvanizing Furnace for Wire. *Canadian Foundryman,* Vol. 22, Apr. 1931, page 11.

Brief description, accompanied by 1 photograph, of an electrically heated and controlled furnace operating at the Hamilton (Ontario) plant of the Frost Steel and Wire Co., Ltd., for the continuous galvanizing of steel wire. OWE (23)

Induction Furnace with an Automatic Temperature Control by Means of a Ferro-Magnetic Muffle. (Four a induction a moufle ferro magnétique autorégulateur de température.) R. Perrin & V. Sorrel. *Revue de Metallurgie,* Vol. 28, Aug. 1931, pages 448-452; *Aciers Speciaux, Metaux et Alliages,* Vol. 6, July 1931, pages 352-353.

The use of magnetic induction permits the very accurate regulation of the temperature ranges of a muffle furnace in which the muffle itself acts as a heat generating unit. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 280. GTM+JDG (23)

Continuous Furnace for Normalizing Sheets. *Iron & Coal Trades Review,* Vol. 122, Apr. 10, 1931, pages 581-582.

The hearth of this furnace is moved in strokes of 2 ft. each by hydraulic power at 750 lbs./in.^{2} The output is about 2 tons/hr. There is no water cooling; the fuel consumption is less than 1¾ cwt. (196 lbs.) coal/ton of sheets normalized. The furnace is in operation at the plant of John Lysaght, England. Ha (23)

Rotary-Hearth Furnace for Annealing. *Iron Age,* Vol. 126, July 10, 1930, page 97.

Describes motor driven furnace having rotating hearth for open or box annealing, or carburizing. It is made by King-Taudevin & Gregson, Sheffield. This design is being introduced into the U. S. by the H. L. Dixon Co., Pittsburgh. Port arrangement, use of recuperators and of gas and air control effects a low fuel consumption even with reduced atmosphere. Furnace is generally designed for producer gas fuel, although natural gas, oil or tar may be used. Approximately 225 lb. of coal/gross ton of steel, not including boxes, is average figure for English practice. VSP (23)

Rotary Hearth Furnace for Heat Treating. R. E. Barker (H. L. Dixon Co.). *Heat Treating & Forging,* Vol. 16, Sept. 1930, pages 1189-1190; condensed in *Fuels & Furnaces,* Vol. 8, Sept. 1930 pages 1257-1258; *Steel,* Vol. 87, July 1931, page 51.

Describes furnace designed by King-Taudevin & Gregson, Ltd., Sheffield, England, in which low fuel consumption is effected by improved port arrangement. Any degree of reducing atmosphere may be obtained by accurate control of air and gas supply. This has increased the life of the pots at least 6 times. Furnace is generally designed for producer-gas, although construction may be modified for natural gas, oil or tar. MS (23)

Industrial Furnaces for Gas. IX. Small Forge Furnaces. X. Large Forge Furnaces. Lawrence Biemiller, *American Gas Journal,* Vol. 135, Oct. 1931, pages 68-69; Nov. 1931, pages 62-63.

IX. The design and construction of small forges is discussed. Suggested uses are: tool dressing, hardening, annealing, and brazing. Gas has been used extensively in this type of furnace owing to its convenience and the ease of its use. Oil is often used in larger forges. X. Since large special forge furnaces handle large tonnages of metal and use large quantities of fuel, the most important features of furnace design such as material handling equipment, automatic temperature control, automatic furnace pressure control, efficient insulation, preheated air and refractories of long life are necessarily observed. Small billets, up to 6 or 8 ins. in each dimension are often heated in a rotary hearth furnace. Medium sized billets are handled in "straight thru" furnaces whereby the billets are pushed by mechanical or hydraulic pushers over water cooled skid rails. The walking beam furnace is also used extensively especially for heating brass billets. A very complete description of the design and operating data of this type of furnace is given. Very large individual forgings such as the forging for a reaction chamber of an oil cracking unit (which is 45 feet long, 6 feet in diameter inside, with walls 6 inches thick), are often heated in large oven furnaces, sometimes of a temporary construction. CBJ (23)

Coke-Oven and Blast-Furnace Gases for Metallurgical Furnaces. *Iron & Coal Trades Review,* Vol. 123, Oct. 2, 1931, pages 506-507.

Some recent developments in Germany are described and the installations are illustrated. Ha (23)

The Reactivity of Coke Coated with Lime and the Production of Low-Carbon Iron in the Cupola. *Foundry Trade Journal,* Vol. 45, Sept. 3, 1931, page 151.

Translation of an article by E. Piwowarsky which appeared in *Die Giesserei.* Piwowarsky has shown that it is not correct to assume that coke is rendered less reactive with carbon dioxide by coating it with lime. A series of experiments are described with the object of supporting this contention. The article also refers to Corsalli's criticisms of Piwowarsky's results, which appeared in a later issue of the German journal. Corsalli opines that the behavior of lime-coated large-size coke cannot be compared with that of small pieces, such as were used in Piwowarsky's experiments. Further, the method usually adopted in treating coke with lime is not as simple as that suggested by Piwowarsky; in fact, coke may be protected by lime to such an extent as not to be burned at all in the cupola. OWE (23)

Investigations on the Coking Power and the Swelling of Coal. H. A. J. Pieters. *Fuel,* Vol. 10, Nov. 1931, pages 484-488.

A method is described for the determination of the velocity of gas evolution from coal which is being heated at a constant rate, which appears to be a valuable characteristic of coal. The velocity of gas evolution attains some typical maxima corresponding with (a) the loss of water, (b) the decomposition during the period of low temperature carbonization, (c) the carbonization of semi-coke. All good coking coals show a characteristic maximum in the velocity of gas evolution at about 480° C. Poorly coking coals are decomposed at a more constant rate. WAT (23)

A New Cyanide Furnace. R. F. James & Glenn Coley (Detroit Edison Company). *Journal Franklin Institute,* Vol. 211, Mar. 1931, pages 327-334.

Illustrates new electrically heated cyanide pot for hardening steel. The heating element is made of usual Cr-Ni alloy. With electrical input of 43 kw. after 1800 work hours, no deterioration of elements had occurred. Used for hardening steering gear sectors, this furnace consistently produced over 4 lbs. of work/kwh. The writers found that (1) cyanide or its components have a harmful effect upon Cr-Ni alloys; (2) the reaction between these 2 materials increases rapidly with an increase in temperature and 1650° F. is the maximum safe temperature for economic operation; (3) it is not economically practical to exclude cyanide or its components from the element chamber; (4) the deterioration of Cr-Ni heating elements heated in air is exceedingly slow (at temperatures below 1800-2000° F.) DTR (23)

Tonnage Melting by Coreless Inductions. E. F. Northrup. *Fuels & Furnaces,* Vol. 9, Apr. 1931, pages 473-478; May 1931, pages 603-605; June 1931, pages 711-715; July 1931, pages 833-838; Aug. 1931, pages 923-928; Sept. 1931, pages 1067-1072.

The coreless induction furnace is most appropriate for the production of C-free metals and alloys because no C is used, either as electrode or in any other way. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 281. Ha (23)

REFRACTORIES & FURNACE MATERIALS (24)

Silicon Carbide and Its Application in Metallurgy. H. R. Houchins & C. McMullen (Carborundum Co.). *Metals & Alloys,* Vol. 3, Jan. 1932, pages 12-14.

6 references are cited. Application of silicon carbide as a resistor material in heat treating furnaces operating at temperatures higher than ordinary metal resistors will stand is discussed. Use of carborundum in recuperators, combustion chambers, and muffles is efficient on account of the refractoriness of the material and its high thermal conductivity. It does not store up quantities of heat. Lesser uses as bonded brick in non-ferrous melting furnaces, in graphite crucibles, and as an outer protection tube for thermocouples are described. WLC (24)

The Manufacture of Magnesite Bricks. *Chemical Engineering & Mining Review,* Vol. 23, June 5, 1931, pages 335-336.

A deposit of magnesite near Attunga, N.S.W. is now the main source of supply for magnesite brick manufacture in Australia. Austrian and Attunga dead-burnt magnesites are compared in chemical analysis. The Austrian product contains about 7% Fe_2O_3, which lowers the temperature at which the material will sinter during calcination and acts as a bond. The Attunga magnesite with a bond of mill scale was found to make excellent bricks. The manufacture is reviewed. WHB (24)

Control and Testing of Refractories in Gas-Works. M. G. Charlet. *Gas Journal,* Vol. 194, June 10, 1931, page 831.

Reviews paper presented before the Annual Congress of the Association Technique de l'Industrie du Gaz en France, Apr. 21 to 25, 1931. The object of the tests is 2-fold: first, the control of the quality of the standard materials employed, and second, the investigation of new products. Cracks, flaws and inclusions of fusible matter and dimensions are checked and inspected. MAB (24)

Steel Industry Favors Dolomite and Chromite Refractories over Magnesite. *Brick & Clay Record,* Vol. 79, July 28, 1931, pages 80, 82.

Statistics reveal, at present, a preference for dolomite and chromite materials. Of these, about 40-70 lbs. of dolomite/ton of steel is at present used as a patching material. Ha (24)

Crucibles of Graphite. (Über Graphit-Tiegel). E. R. Thews. *Tonindustriezeitung,* Vol. 56, Jan. 14, 1932, pages 60-62.

The composition and properties (resistivity against chemical attack and heat, heat conductivity etc.) of the many types of graphite crucibles are described as they are used for metallugical purposes. Some important points which are to be observed in the manufacture of crucibles are discussed. GN (24)

INSPECTION (26)

Magnetic Inspection of Rails. *Metallurgist,* Dec. 1930, pages 189-190.

Acoustical, electrical and magnetic properties of rails have been used for detecting defects. The Sperry electrical method is quite well known in America. The magnetic method has been more widely used in England. The leakage of magnetic flux is measured or looked for rather than the determination of total internal flux. This leakage method appears especially applicable for detecting cracks and fissures. In one form of test, the rail or other part is suitably magnetized and then treated with finely divided iron particles suspended in a liquid medium, by pouring the liquid mixture over or spraying it on to the surface. Where leakage occurs, as it does at a fissure, the magnetic poles attract the iron particles, which collect about them. Fine cracks, difficult or impossible to detect by visual inspection, can be revealed in this way on smooth surfaces. This method is now in use in England by railway and motor transport companies for regular inspection of important steel parts, such as wheel axles, liable to failure through fatigue cracking. In another form of test, the leakage flux is detected electrically by means of current induced in a traversing search coil when it encounters the magnetic leakage field. This form of test has been developed particularly for testing rails *in situ.* A portable apparatus, developed by Suzuki in Japan and recently mounted by Sakurai on one continuously moving truck is described. VVK (26)

The Spark Test as a Production Tool. A. K. West. *American Machinist,* Vol. 75, July 9, 1931, pages 72-74.

The nature and shape of sparks produced when grinding permit the differentiation and distinguishing of alloy steels. A few photographs illustrate some typical examples. Ha (26)

A Mirror Comparator for Production Inspection. O. P. van Steewen. *American Machinist,* Vol. 75, Sept. 10, 1931, pages 417-418.

A combination of optical and mechanical transference produces a magnification of 1000:1, so that an error of 1/1000 in. would show 1 in. deflection in the microscope. Arrangement of the device on the work piece is illustrated. Ha (26)

EFFECTS OF ELEMENTS ON METALS & ALLOYS (27)

The Influence of Third Metals on the Constitution of Brass. III. Influence of Tin. (Der Einfluss von dritten Metallen auf die Konstitution der Messinglegierungen, III Der Einfluss von Zinn). O. Bauer & M. Hansen. *Mitteilungen der deutschen Materialprüfungsanstalten,* Sonderheft 17, 1931, pages 3-20.

Attention was confined to the region between 52 and 66% Cu, 0.5 and 5% Sn, 33 to 47% Zn. The diagrams and conclusions of previous workers are discussed. In the experimental work, 30 alloys were studied by thermal analysis and microscopically examined after long annealing and quenching from 800°, 700°, 600°, 575°, 550°, 525°, 500°, 475°, 450° and 400° C. The ternary equilibrium diagram is shown and many pseudo-binary diagrams plotted for constant Cu and Sn content. Sections of the ternary solid diagram are shown for the different quenching temperatures. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 250. HWG (27)

Some Uses of Aluminum in Steel. W. F. Darch. *Western Machinery World,* Vol. 22, Dec. 1931, pages 570-572.

Lightness, electrical and thermal conductivity, ability to resist corrosion, high ductility and strength when alloyed with small amounts of certain other metals and heat treated have combined to place aluminum in a prominent position in the manufacture of steel. Calorizing is reviewed. Aluminum is an important constituent in the thermit-welding process. Aluminum is a necessary element in steels which are to be successfully nitrided. WAT (27)

Nickel Cast Iron in the Automotive Industry. Thos. H. Wickenden. *Nickel Cast Iron News,* Vol. 2, Aug. 1931, pages 3, 10.

A few cast iron compositions with Ni additions for cylinder block specifications are given. The advantages of adding Ni either alone or with other alloying elements are: (1) refining the grain by producing finer graphite flakes and securing a high lustre on a finished surface; (2) reduction of porosity and internal shrinking resulting in pressure-tight castings; (3) eliminating chilled corners and edges and other spots in gray iron, thereby improving the machinability; (4) increasing the hardness of gray iron, especially in heavy sections retaining the machinability above 300 Brinell; (5) equalizing the hardness in thick and thin sections, resulting in reduction of casting strains and resulting warpage; (6) securing great resistance to wear and abrasion; (7) Securing stability of composition, strength and hardness at elevated temperatures. The particular advantage for use in brake drums is noted. Ha (27)

How Silica and Silicon Affect Die Casting Machineability. G. L. Werley & E. A. Anderson. *Iron Age,* Vol. 128, July 16, 1931, pages 183-186.

Describes experiments conducted on alloy containing 4% Al, 3% Cu, 0.1% Mg and the balance high grade Zn, commonly known as "4-3-0.1" alloy. Castings containing 0.38% silica dulled tools rapidly. Even castings containing 0.01% silica were injurious to the tools. Silica is not detrimental to tensile strength and Brinell hardness. Neither is it soluble in 4-3-0.1 alloy. Si has no appreciable effect on the machinability of Zn alloy die castings. Si may be oxidized to silica in the alloy. VSP+Ha (27)

Silicon and Manganese. (Silicium et Manganèse.) Try-Chalons. *Revue Fonderie Moderne,* Vol. 25, Sept. 10, 1931, page 334.

To obtain good quality of castings from a cupola furnace, the composition of the charge should be selected according to the thickness of the pieces to be cast and to the corresponding velocity of cooling. The contents of Si and Mn must be adapted correspondingly. A table showing the most suitable contents of Si and Mn for thicknesses from 3-50 mm. is given. For very low C, Si should be increased a little for thin castings. Ha (27)

INSTRUMENTS & CONTROLLERS (28)

Ladle Heat Measured Quickly and Accurately. R. D. Bean. (Brown Instrument Co.) *Metal Progress,* Vol. 20. Oct. 1931, pages 60-63, 104.

The author describes an immersion pyrometer for the measurement of the temperatures of foundry metals such as Al and brass with a discussion of the use of the instrument. WLC (28)

Measurement and Control of Temperature in the Hardening Shop (Temperaturmessung und -regelung in der Härterei). A. Grunwald. *Feinmechanik und Präzision,* Vol. 39, Oct. 1, 1931, pages 151-156; Nov. 1, 1931, pages 179-183.

The importance of exact temperature measurement and temperature control particularly in the hardening process is pointed out. The hardening heat must not exceed that which is absolutely necessary, it must last a certain time and only as long as all parts have assumed uniform heat, and tempering must be carried out at a certain temperature best suited for the particular steel. If these precautions are not observed, hardening cracks occur, the steel is overheated and is burnt, or an upsetting effect takes place. The instruments for the supervision of this process, radiation pyrometers, thermocouples, resistance thermometers, and their accessories are thoroughly treated; their principles are explained and connections illustrated. Ha (28)

Automatic Combustion Control Systems for Wire Furnaces. F. Aschner & H. Mayer-Witten. *Wire & Wire Products,* Vol. 6, Nov. 1931, pages 440-441, 446.

As the economy of the process and the quality of the production in the manufacture of wires depends greatly on the uniformity of temperature, the control of furnaces has become of utmost importance. In this article automatic controlling systems and the types of regulators used in Germany are described; full layouts are given and installations illustrated. Ha (28)

Recent Advances in Pyrometry. Ezer Griffiths. *Journal Institute of Metals,* Vol. 47, June 1931, pages 1-4.

This review covers recent progress in pyrometry, particularly high-temperature measurements of the melting points of metals. For the calibration of instruments, several points of the International Scale are available:

Temperature of freezing Zn	419.45° C.
Temperature of freezing Sb	630.5° C.
Temperature of freezing Cu in a reducing atmosphere....	1083° C.
Temperature of freezing palladium	1555° C.
Temperature of melting W	3400° C.

Thermoelectric recorders and optical pyrometers are described and surface pyrometers and accessory apparatus and a high-frequency furnace for obtaining high temperatures are treated. Ha (28)

Temperature Measurements of Liquid Copper and Its Alloys (Ueber Temperaturmessungen an flüssigem Kupfer und seinen Legierungen). H. Miething & Ch. Winkler. *Die Giesserei mit Giesserei-Zeitung,* Vol. 18, Feb. 27, 1931, pages 181-184.

Immersion pyrometers are subject to great wear and, therefore, are not suitable for a continuous supervision of the pouring temperature. For this reason, an attempt was made to determine how exactly radiation pyrometers indicate the temperature as the liquid metal cannot be considered a black body. The measurements described were made with a Holborn-Kurlbaum pyrometer on pure Cu, phosphor-bronze, bronze B, bronze 4, bearing bronzes and red brass, and brass. The exact analyses for these alloys are given. Where possible, several color filters were used. The corrections for the measurement at the free-radiating surfaces are determined and tabulated for all metals. The agreement with the immersion measurements are fairly good except for those metals which emit vapors when great differences due to absorption can take place. Ha (28)

On the Platinum Resistance Thermometry. Part 1. Calibration of Bridge and Annealing of Platinum Bulb. Part 2. Determination of Constants of Platinum Bulb and Accuracy of Resistance Thermometry. Mototaro Matsui & Shuu Kambara. *Journal Society of Chemical Industry,* Japan, Vol. 33, Oct. 1930, pages 401B-403B, 403B-407B.

The accuracy of resistance thermometry is 0.01° C. against temperature below 500° and 0.1° against temperature above 500°. They have not, however, a fixed point above 500° which, determined to 0.01° and to obtain any temperature above 500° which has reproducibility to 0.01°, is difficult. Hence the resistance thermometry may be said as the most accurate measurement of temperature at the present time. MAB (28)

Temperature Regulator for Melting Furnaces (Temperaturregler für Schmelzofen). H. Rechenberg. *Elektrotechnische Zeitschrift,* Vol. 52, Dec. 3, 1931, pages 1498-1499.

A platinum resistance in the furnace changes its resistance with the temperature and disturbs the balance of a Wheatstone bridge of which it forms one leg. The galvanometer is deflected and closes, according to the direction of the deflection the circuit of an amplifying tube which operates through a relay, a resistance in the heating circuit of the furnace. A curve of a run at 850° C. is given which shows deviations of less than $\pm$ 1° C. Ha (28)

Galvanizing Pot Temperature Control Made Automatic. H. R. Simonds. *Steel,* Vol. 89, Oct. 5, 1931, pages 39-43.

A brief description of pyrometric control of temperature of a few plants with galvanizing pots of 30 and 50 tons. The thermocouple is suspended over the edge of the pot and immersed in the molten zinc. Ha (28)

An Object Stage Which Can be Turned in Any Direction. (Ein allseitig drehbarer Objekttisch.) M. Straumanis. *Zeitschrift für technische Physik,* Vol. 12, Nov. 1931, pages 576-578.

The author designed a simple object stage which can be turned to any direction during crystallo-physical, crystallographic and metallographic work. EF (28)

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

Cold Treating Duralumin Rivets. Robert Johnson. *Metal Industry,* N. Y. Vol. 29, Sept. 1931, page 383.

Rivets of heat treated and quenched duralumin, when kept at 10° F, did not harden at the end of 1 wk. and at the end of 2 wks. had hardened only slightly. When housed in wooden boxes containing dry ice, such rivets are kept in condition for 1 day around a plant. PRK (29)

Engineering Requirements for Heat Resisting Metals. J. C. Woodson, *Heat Treating & Forging,* Vol. 17, July 1931, pages 700-705, 709; Aug. 1931, pages 796-799.

The application of such metals in metallurgical processes is discussed. Malleable and cast resistors for furnace resistor elements and their classification for use with different temperatures are described. Examples and compositions for different purposes are given and recommendations for future improvements are added. Ha (29)

Quick Determination of Limiting Creep Stress. Correspondence from W. Rosenhain, London, England. *Metal Progress,* Vol. 21, Feb. 1932, pages 65-66.

The writer discusses the intercrystalline failure of metals at elevated temperatures. The shortcomings of creep measuring devices described are pointed out. Kinship between this type of failure and fatigue is suggested. WLC (29)

The Coefficient of Expansion of Cast Iron. (Beitrag zum Koeffizienten des Gusseisens.) F. Roll. *Giesserei-Zeitung,* Vol. 27, Jan. 1, 1930, pages 4-7.

A review of the effect of temperature and alloying elements upon the coefficient of thermal expansion of cast Fe. (29)

Behavior of Some Irons and Steels under Impact at Low Temperatures. Robert Sergeson. *Transactions American Society for Steel Treating,* Vol. 19, Feb. 1932, pages 368-384.

Includes discussion. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 284. WLC (29)

Review of June 1931, Chicago (A.S.T.M., A.S.M.E.) Symposium on Effect of Temperature on the Properties of Metals. H. J. French. *Conference on Metals & Alloys, Case School of Applied Science, Cleveland, Ohio.* Paper No. 11, Nov. 1931. Mimeographed. 14 pages.

A general abstract of the Symposium papers. (See *Metals & Alloys,* abstract section, Vol. 2, Sept. 1931, pages 191-193; Oct. 1931, pages 231-232; Nov. 1931, page 283; Dec. 1931, pages 324-325 for abstracts of individual papers.) Ha+HWG (29)

Monel Metal and its Utilization at Elevated Temperatures. (Monel Metall. Über die Verwendung in der Wärmetechnik.) A. Schulze. *Die Wärme,* Vol. 53, May. 1931, pages 334-337.

The thermal and mechanical properties of Monel metal are briefly reviewed and its utilization as construction material is discussed with particular reference to turbine blades. EF (29)

Corrosion Problems Affecting Oil-Vapor Condensers. A. E. Pew. *Refiner & Natural Gasoline Manufacturer,* Vol. 10, May 1931, page 79.

Corrosion from the water side and oil side of condensers and the effect of modern design on the corrosive action are discussed. The salts can be removed from the water but there generally remains 5.5 cc. of O/liter. The action of this gas can be minimized by keeping the pH value above 10. On the oil side of the tube, corrosion is due to S and its gaseous derivatives and to salts and their acid derivatives. The enlargement of the distance and fractionating equipment has increased the use of the tubular condenser over the submerged coil. The high velocity of the cooling medium in the tubular condenser, 3.5-5 ft./sec., means vapor velocity of 50-90 ft./sec., which causes high erosion unless the design is right. Outlet-water temperature should be limited to 140° F. or lower. At 170° F. scaling followed by dezincification of admiralty metal tubes occurs. With water-outlet temperature of 135° F. and vapor-inlet of 600° F., salt water can be used successfully as the cooling medium. The choice of materials of construction is also thoroughly discussed. WAT (29)

Tensile Properties of Boiler Plate at High Temperatures (Festigkeitseigenschaften von Kesselblechen bei erhöhten Temperaturen). A. Pomp. *Stahl und Eisen,* Vol. 50, Dec. 11, 1930, pages 1737-1741.

The elastic limit, tensile strength, elongation and reduction in area of 12 boiler-plate steels have been determined at the ordinary temperature and at 300°-500° C., and the results are shown in tables and graphs. These indicate that there is a relation between the tensile strength at the ordinary temperature and the elastic limit at high temperatures up to 500° C. WAT (29)

On the Thermal Expansion of the Alloys of Iron, Nickel and Cobalt, and the Cause of the Small Expansibility of Alloys of the Invar Type. H. Masumoto. *Kinzoku no Kenkyu,* May 1931, pages 237-252; *Science Report, Tohoku University,* Series I, Vol. 20, 1931, pages 101-123.

The mean coefficient of thermal expansion between 30° and 100° has been determined for binary and ternary alloys of iron, nickel and cobalt. Generally speaking, the hexagonal solid solution has a greater, and the α solid solution a smaller coefficient of expansion than the γ solid solution. The expansion coefficient-concentration curve in the iron-nickel system has a maximum at a 25% Ni content and two minima at 18 and 36.5% Ni. In the iron-cobalt system, it has two breaks at about 79 and 95% Co content and an inconspicuous maximum at 35% Co, and in the nickel-cobalt system, it has a break at 70% Co. In the case of the ternary system of iron-nickel-cobalt, the minimum at 18% and the maximum at 25% Ni content found in the expansion coefficient-concentration curve of iron-nickel alloys, diminish first rapidly and then gradually with the addition of cobalt till they almost disappear at 40% Co content. The small coefficient of expansion of invar containing 36.5% Ni rapidly diminishes with an increasing content of cobalt in the alloy; it reaches a minimum at about 5% Co, and afterwards rapidly increases. For alloys having small expansibility, the measurement of thermal expansion was made from the liquid air temperature up to the vicinity of the critical point, and the available range of temperature for the small expansibility has been examined. The value of the smallest coefficient of expansion obtained here was less than 10^{-7}. An addition of a small content of manganese to the ternary alloys having a small expansibility lowers the Ar_3 transformation. A theory is proposed, by which the small expansibility of invar is satisfactorily explained from magnetic data, without assuming the existence of a compound Fe_2Ni or the A_3 transformation. The theory is as follows: the small expansibility depends upon the ferromagnetic state of the alloy, the paramagnetic state of the same alloy having greater expansibility. The mean coefficient of expansion of an alloy is shown by $\epsilon = \delta - \frac{\kappa I_\infty}{\Theta}$, where δ is the inclination of the paramagnetic part of the expansion-temperature curve, I_∞, the saturated magnetisation Θ, the temperature of A_2, κ, a constant. Iron-nickel concentration curve has a maximum of κI_∞ at about 40% Ni, and hence a minimum of ϵ at 36.5% Ni. If 5-6% Co is added the value of ϵ attains 10^{-7} or less. KT (29)

Designing High Temperature Steam Piping, Part I. Flexibility of 1000° F. Line. Arthur McCutchon. *Heating, Piping & Air Conditioning,* Vol. 3, Oct. 1931, pages 825-831.

An installation of a turbo-generator unit design to operate with steam at 1000° F. in the Delroy power house of the Detroit Edison Co. tests the theories of design quite as severely as it does the metals of which the unit is constructed. Engineering studies involved in the actual layout of this piping to provide for the movement due to expansion and a means of compensating for the effects of "creep" on certain of the flange joints have more than a nominal interest. The material used in this unit is the 18-8 type Cr-Ni steel, containing about 0.15% C. A chart is presented showing the linear expansion of this steel as compared with a medium carbon steel to temperatures of 1100° F. A distinct characteristic of this type of alloy is an unusually high coefficient of linear expansion. A similar chart is also given for the modulus of elasticity. The elastic modulus for the 18-8 steel decreased from 27 million lbs./in.^{2} at room temperature, to about 21 million at 1200° F. Calculations at 1000° F. used 21.6 million lbs./in.^{2} as a basis. The total allowable working stress, considering bending plus longitudinal pressure was placed at from 6,000 to 7,000 lbs./in.^{2} for the material used. The type of design employed to compensate for the linear expansion and "creep" will be discussed in Part 2 of this article to appear in the future. WAT (29)

Creep Determinations on Structural Steels at High Temperatures. *Metallurgist,* June 1931, pages 85-86.

An extended abstract of the work of Pohl, Scholz, & Juretzek, *Archiv für Eisenhüttenwesen,* Aug. 1930. See *Metals & Alloys,* Vol. 2, Feb. 1931, page 51. VVK (29)

REDUCTION METALLURGY (31)

Investigations on the Agglomeration of Siegerland Siderite by Coking with Coal (Untersuchungen über die Stückigmachung von Siegerländer Feinspat durch Verkoken mit Kohle). W. Luyken & E. Bierbrauer. *Archiv für Eisenhüttenwesen,* Vol. 4, May 1931, pages 505-511; *Stahl und Eisen,* Vol. 51, June 11, 1931, pages 739-740.

Report No. 27 of the Committee on Ores of the Verein deutscher Eisenhüttenleute. Siegerland siderite of various grain sizes was mixed with coal and coked in a small experimental furnace of 200 kg. capacity. The coal-iron ore mixtures contained 25%, 34% and 43% ore. Size and impact strength were determined. By dropping the coked product, having a grain size above 60 mm. 4 times from a height of 1.80 m., 90.8% of the coked product retained a grain size above 40 mm. when the amount of ore in the mixture amounted to 34%; 87.7% of the coked product had a grain size above 40 mm. when the amount of ore constituted 43% of the mixture. In coking the same coal without adding ore, an impact strength of only 80-85% is obtained. In adding ore, however, the loss of ammonia gas and benzol increases with increasing amount of ore. After these preliminary tests, tests on a large scale were made which showed the same favorable properties of the coked product. An essential advantage of this ore-coke is its high reactivity which amounts to 75-90% in comparison with 27-30% of the coke which does not contain ore. During the coking, up to 75% of the Fe content of the ore is transformed to metallic Fe. In spite of the previous unfavorable experience with Fe bearing coke in the blast furnace, its use seems to be favored by the above noted high reactivity. This new process seems to guarantee the economy of ore mining in the Siegerland ore mining district. GN (31)

Preliminary Tests on the Use of Coking Coals in Metallization of Iron Ores. W. R. McClelland. *Canada Department of Mines, Mines Branch Report* No. 720, 1931, pages 199-201.

A mixture of 24.36% magnetite and 19.12% hematite was successfully metallized by the Musso process using coking coals. Details of 3 tests are given. AHE (31)

New Process of Zinc Reduction. *Metal Industry,* London, Vol. 38, May 15, 1931, page 499.

Details are given of the experimental production of Zn by reduction of zinc oxide by methane. The information is taken from circulars issued by the Department of Commerce, Bureau of Mines, Washington. *Metals & Alloys,* Vol. 2, Aug. 1931, page 155. PRK (31)

Modern Installations of Blast Furnaces and Hot Blast Apparatus (Installations modernes de hauts fourneaux et d'appareils a vent chaud). *Revue Technique Luxembourgeoise,* Vol. 23, Sept.-Oct. 1931, pages 207-209.

Description and construction data of 3 new blast furnaces of 500 tons daily output and a volume of 867 m.^{3} Ha (31)

Oxidation from the Point of View of Heredity (Die Oxydation unter Berücksichtigung der Vererbung). *Giesserei mit Giesserei-Zeitung,* Vol. 18, Nov. 6, 1931, page 866.

Paper for the Scientific Committee of the Association Technique de Fonderie de Belgique at the Foundry Congress, Milan, Sept. 1931. The different behavior of chemically equal pig irons is traced to the influence of oxidation during the melting in the blast furnace. The conditions are not fully explained and require further investigation. Ha (31)

True Pyrite Smelting. Arthur J. Caddick. *Metal Industry,* London, Vol. 36, May 30, 1930, pages 577-578.

Usual amount of coke used varies with the class of ore treated, grade of matter required and furnace practice. Gives particulars of practice for 2 blast furnaces, each smelting 16,000 tons without the use of any carbonaceous fuel. This, according to the author constitutes a world record. Gives a record of the 2 furnaces. The success of the smelting operation depends upon a strict watch of ore mixture required at the time according to general condition of the furnaces and upon proper amount and pressure of blast. VSP (31)

Blast-Furnace Data and Their Correlation. Part 2. E. C. Evans, L. Reeve & M. A. Vernon. *Iron & Steel Institute, Advance Copy* No. 6, May 1931, 68 pages; *Iron & Coal Trades Review,* Vol. 122, May 8, 1931, pages 743-753; *Engineering,* Vol. 131, June 9, 1931, pages 807-810.

The mathematical expressions given by Evans and Bailey in Part 1 are modified slightly to agree with additional data. Operating results from over 220 furnaces are given and discussed. For an individual furnace, as the time of stock descent decreases the iron factor (pounds of C burnt to CO in hearth per ton of pig iron) increases, and the advantages gained by increasing the output over a certain amount are counterbalanced by increased hearth requirements. For optimum fuel consumption and output, the time of stock descent for rich burdens is less than that for poor burdens. Detailed records for one blast furnace are given and analyzed. 9 references. LFM+JLG+Ha (31)

The Flash Roasting of Iron Pyrites. Horace Freeman. *Chemical Age,* London, Vol. 25, Aug. 1, 1931, pages 111-112.

The pyrite preferred for the flash-roasting process is flotation pyrite dried down to 2-3% moisture content and containing about 50% S (dry basis). See *Metals & Alloys,* Vol. 2, Sept. 1931, page 194. (31)

Reduction of Lead Ore without Coke. (Brennstofflose Bleierzverhüttung.) N. C. Kyriacou. *Metall und Erz,* Vol. 28, Sept. 1931, pages 447-451.

Contains 16 references. Lead ore is roasted with sand and lime to burn out sulphur forming PbO and $PbSO_4$. $PbSO_4$ is then broken up with the formation of silicates. At the same time the material changes from powder to granular form. The roasting is done in a rotary furnace 40 m. long, taking about 2 hrs. Good results in reduction have been obtained by using anthracite powder instead of coke. 10 to 15% is added to a 2500 kg. charge of lead oxide. A hot fluid slag containing only 0.25 to 0.55% Pb is formed. The process is very economical and is much cheaper than the ordinary coke process. CEM (31)

MANUFACTURERS' LITERATURE REVIEWS

In this department we each month list the catalogs and other printed matter issued by manufacturers. Unless otherwise noted, any of the items listed may be secured free upon application to the issuing firm. Manufacturers who have not yet sent in their printed matter are invited to do so.

314 **Chrome Brick**—Bulletin 1-13-15 of E. J. Lavino & Co., Bullitt Bldg., Philadelphia, Pa., stresses the unusual chemical and refractory properties of chrome ores in the manufacture of refractories. Physical properties of brick made by their improved process are illustrated. Several of their pamphlets show the application of these bricks in basic open-hearth furnaces, in soaking pits and recovery furnaces.

315 **Blowers**—Bulletin No. 500-1 of the Northern Blower Co., W. 65th St., Cleveland, Ohio, is devoted to their continuous operating air filters, giving details of construction and operation.

316 **Bright Annealing**—A leaflet sent out by the Process Engineering & Equipment Corp., Attleboro, Mass., calls attention to their special atmosphere electric conveyor furnaces, installed to replace two fuel fired batch type furnaces and to eliminate pickling, cleaning and drying equipment. Another leaflet issued by the same company describes their furnaces for copper brazing.

317 **Air Tools**—Catalog AG-200 of the Madison-Kipp Corp., Madison, Wis., is devoted to their Air Chippers ,which may be used for swaging, riveting, scraping, wood chiseling, stone chipping, etc., and their Air Grinders. Grinding wheels, smoothing stones and buffing tips for use in this latter machine are illustrated. A price list is included.

318 **Special Alloys**—A leaflet issued by the Federated Metals Corp., 295 Madison Ave., New York, lists their special alloys, indicating their uses and compositions.

319 **Metal Testing Machinery**—Catalog 390 of Louis Schopper, sent out by Testing Machines, Inc., 314 Broadway, New York, illustrates measuring appliances for investigating the strength of materials. Machines for carrying out tests respecting tensile properties, compression, bending, etc., Ball hardness testers and pendulum impact testers are described.

320 **Hydraulic Tables**—Bulletin No. 25 of the Baldwin-Southwark Corp., Philadelphia, Pa., is a compilation of data of interest and value to those engaged in the design or use of hydraulic equipment.

321 **Cadmium Plating**—The January issue of the Udylite News, published by the Udylite Co., Detroit, Mich., contains a résumé of the articles that have appeared in the bulletin during the year 1931. There is also a description of an electric windshield defroster which is finished in Udylite.

322 **Hardening High Speed Steel**—Bulletin No. 1012-2 of the Sentry Company, Taunton, Mass., describes their Diamond Block method of hardening high speed steel. The bulletin is illustrated with micrographs. The same company has developed a non-metallic tray to be used in connection with this hardening method. High speed tools hardened by this method are said to retain their original surface free from scale, soft surfacing or carburization.

323 **Annealing Furnaces**—Leaflets describing their electric bell type annealing furnaces may be obtained from the Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

324 **Die Castings**—An attractive booklet describing their aluminum die castings has been prepared by the Aluminum Company of America, Pittsburgh, Pa. The booklet is profusely illustrated.

325 **Steel Pipe and Tubes**—A 39-page bulletin issued by the National Tube Co., Pittsburgh, Pa., is devoted to their stainless and heat resisting pipe and tubes with particular reference to U S S 18-8 alloy tubular products. Extensive tables show their resistance to various chemicals and different sections of the booklet discuss their fabrication and metallurgical properties.

326 **Dehumidification of Air**—Special Development Bulletin No. 16 of the Dow Chemical Company, Midland, Mich., is a very thorough discussion of the dehumidification of air by calcium chloride. It contains data which is reliable and directly applicable to humidifier design.

327 **Fluxes**—A leaflet issued by Krembs & Co., 669 W. Ohio St., Chicago, Ill., lists their fluxes and indicates the use for which each kind is intended. Prices are included.

ALPHABETICAL INDEX TO ADVERTISERS

◆ ◆ ◆

328 **Chain Drives**—The Link-Belt Co., 501 N. Holmes Ave., Indianapolis, Ind., has sent out a leaflet announcing their 3/16" pitch silent chain.

329 **Non-Ferrous Castings**—The Development and Research Department of the International Nickel Co., 67 Wall St., New York, N. Y., has recently issued a booklet entitled "The Use of Nickel in Non-Ferrous Castings." In this report the effect of nickel on the properties of brass and bronze is noted. Several useful tables are given showing typical compositions of nickel for various purposes. A list of special alloy compositions containing nickel, with their trade names is convenient for reference.

330 **Steel Foundry Phraseology**—The January issue of *Research Group News*, published by the Electric Steel Founders' Research Group, 541 Diversey Parkway, Chicago, Ill., features an article on steel foundry phraseology which includes a short glossary of foundry terms. The same issue contains an article entitled "First and Final Costs as Influenced by Design."

331 **Carburizing Furnaces**—A late bulletin of the Surface Combustion Corp., Toledo, Ohio, is devoted to their continuous gas carburizing furnaces and contains an article on one of their units installed by the Chrysler Corporation.

332 **Gas Producer**—Bulletin No. 45 of the Semet-Solvay Engineering Corp., 40 Rector St., New York, N. Y., is a very thorough discussion of their Koller type gas producer, and includes a cross section diagram of a typical installation.

333 **Carborundum**—The Carborundum Co., Niagara Falls, N. Y., has compiled a booklet containing full information on cemented tungsten carbide and its characteristics and a detailed explanation of the grinding process.

334 **Foundry Equipment**—The January issue of Better Methods published by the Beardsley & Piper Co., Chicago, Ill., describes an installation of one of their Sandslingers in the Spring City Foundry, Waukesha, Wis.

335 **Boilers**—Combustion Engineering Corp., 200 Madison Ave., New York, N. Y., has just issued a catalog describing the C-E VM type boiler. It is of the bent-tube type and is adapted to plants having limited space conditions.

336 **Lead-coated Copper**—Application of lead-coated copper to vertical surfaces and roofing is illustrated in the February issue of the Bulletin of the Copper & Brass Research Association, 25 Broadway, New York.

337 **The Laboratory**—The Vol. 5, No. 1, issue of this periodical of the Fisher Scientific Co., Pittsburgh, Pa., is a tribute to Justus von Liebig, pioneer in the design of chemical apparatus.

338 **Engineering Achievements, 1931**—The Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa., has issued a collection of descriptions of their technical achievements during the past year, in steam generating plants, transmission, switchgear, transportation and the home.

346 **Illium**—An alloy developed by the Burgess-Parr Co., Moline, Ill., offers remarkable resistance to a great many corrosives. Its physical properties, fabrication and applications are discussed in an attractive booklet issued by the company. It is classed as a non-ferrous alloy composed of nickel, chromium, copper, molybdenum and tungsten with small amounts of iron, manganese, silicon and carbon.

GENERAL (0)

Textbook of Physical Chemistry (Lehrbuch der physikalischen Chemie). *Ferdinand Enke, Stuttgart.* **Vol. I. Basic Principles of Physical Chemistry. The Fluid State of Aggregation of Pure Substances.** 1928. 966 pages. Price 82 RM. **Vol. II. The Solid State of Aggregation of Pure Substances. Dilute Solutions.** 1928. 924 pages. Price 88 RM. **Vol. III. The Statistics of Chemical Reactions in Dilute Mixtures.** 1930. 893 pages. 92 RM. **Vol. IV, Part 1. The Statics of Chemical Reaction. Chemical Kinetics.** 1931. 288 pages. Price 26 RM. Paper, 6½ x 10 inches.

This work is still unfinished. The remaining parts of Vol. 4 and Vol. 5 will contain what might be called "atomic physics." The subjects treated are discussed with clearness and completeness. The viewpoint is inclusive rather than critical. The theoretical discussions are well handled. The experimental methods and apparatus described represent in many cases "classical" rather than modern procedure. For example, Kohlrausch's bridge for the conductivity of solutions is given in detail, but scant mention is made of modern alternating current bridges. In the main, only subjects concerned with "physical properties" and subjects amenable to mathematical theory are presented. The colloidal state of matter is not mentioned. The crystallography section is unusually large, but barely mentions the use of X-rays in this field. One very well known American writer is mentioned only in connection with work he did in Germany in 1894. Another equally prominent American physical chemist gets but little more mention. In applications of thermodynamics the situation is somewhat better. H. W. Russell (0) -B-

Journal of the (British) Institute of Metals, 1931, No. 2, Vol. 46. Institute of Metals, London, 1931. Cloth, 5½ x 8½ inches, 571 pages. Price 31 s. 6d.

This volume of proceedings contains the autumn lecture by U. R. Evans, on Thin Films in Relation to Corrosion Problems, in which he remarks that some people do not believe in thin films because they "will never accept a simple explanation if a complicated one can be suggested; it is possible to offer no help to persons of this mentality; indeed I am assailed by doubts as to whether they are worth helping."

He takes a crack at those who divide metallurgy into ferrous and non-ferrous by commenting, at one point, as follows: "These examples, however, have been taken from iron —a metal which this Institute does not officially recognize, although I cannot but think that some of the members in their private capacity may be dimly aware of its existence."

The other articles deal with oxidation of Cu alloys, protection of Mg alloys against corrosion, attack on steel in hot galvanizing, spectrographic analysis, wire drawing, brittleness of Cu, testing thin Cu strip, work-hardening of Cu, Brinell testing, cold-rolling and heat-treatment of Pb alloys, Duralumin, unsoundness in Al sand-castings, macro-etching of Al-Si alloys, failure of high strength brass, data on Cu Mg, Ni Cu, Au Cu and Ag Hg alloys, melting Ni Cr alloys in hydrogen and with electric furnaces for bright annealing.

As usual, the discussion adds materially to the value of the papers. H. W. Gillett (0)-B-

Effects of Mechanical Treatments on the Strength of Materials Used in Aviation. (Les effets des traitements mecaniques sur la resistance des materiaux employes dans l'aviation). E. Pretet. *Revue de Métallurgie,* Vol. 28, Dec. 1931, pages 661-672.

The final properties of the materials are pronouncedly affected by mechanical working in any stage of their manufacture. A certain amount of mechanical deformation is necessary for all metals, but it must be done correctly. JDG (0)

The World of Metallurgy. John A. Mathews (Crucible Steel Co. of America). *American Institute Mining & Metallurgical Engineers, Preprint,* 1931, 13 pages.

An address delivered at Columbia University, which defines the field of metallurgy and discusses progress in this field. See editorial comment, *Metals & Alloys,* Vol. 3, Feb. 1932, page 28. JLG (0)

The Economic Significance of Specifications for Materials. Value of Specifications in the Manufacture of Steel. John Brunner (Illinois Steel Co.). **The Economic Significance of Specifications from the Standpoint of a User of Steel.** P. Parke (Pullman Co.). **The Economic Significance of Specifications for Materials from the Point of View of a Producer of Concrete.** J. P. H. Perry (Turner Construction Co.). **The Use of Specifications for Concrete from the Point of view of the Consumer.** Arthur R. Lord (Lord & Holinger). **Specifications from the Standpoint of a Large Purchaser of Engineering and Special Materials.** J. W. Bancker (Western Electric Co.). *Journal Western Society of Engineers,* Vol. 36, Oct. 1931, pages 280-301.

A series of 5 papers, read at a joint meeting of the Society with the American Society for Testing Materials, covering the viewpoints of a producer and a consumer of concrete, a producer and a consumer of steel and a large user of other materials. 8 advantages of specifications to the producer or seller, 9 to the consumer or buyer and 5 to the purchasing organization are listed. 4 faults of ill-considered specifications are: (1) unnecessary limitations due to ignorance of the properties governing successful and economic use of the material, (2) ambiguity, resulting in continued controversy, (3) unnecessary incompatibility with standard or commercial practices and (4) inclusion of limitations which the supplier cannot reasonably be expected to meet since the origin of the variation is beyond his control. The trend in specification work continues to be toward simplification and standardization with more coöperative work between those interested. WHB (0)

Steel Metallurgy in 1930. G. R. Fitterer. *Blast Furnace & Steel Plant,* Vol. 19, Jan. 1931, pages 99-100.

Brief review on wrought iron, transportation of metal, rolling mills, open-hearth ports, open-hearth chemistry. Mn-Si deoxidizers, converters, electric furnaces and alloy steels. Ha (0)

Science in Action. E. R. Weidlein & W. A. Hamor. McGraw-Hill Book Company, New York, 1931. Cloth, 6 x 9¼ inches, 310 pages, 32 figures. Price $3.00.

A survey of scientific research as applied to American industries, written for the non-technical "business man" reader, and based upon the authors' experience in directing the work of Mellon Institute.

Such a wealth of material is available on the achievements of scientific research that any one subject is sketchily dealt with. Metallurgy is covered in about a dozen pages all told, and the great bulk of the comment refers to chemistry, largely organic chemistry.

Metallurgy, according to a table shown, leads in the number of separate laboratories studying the problems of a given group of industries, with 226, the runners-up being paints and varnishes, 177; pulp and paper, 166; foods, 155. 20 fields are mentioned, each of which is dealt with by 75 or more laboratories.

Beside the general historical statements which make up the bulk of the book, and which show the bearing research has had on the establishment of new industries and the rejuvenation of old ones, there are chapters on scientific management, on the management of industrial laboratories, and on the qualities needed in research workers.

Much of the book is re-written from more detailed articles and talks which were, in general, rather more effective in their original than in their present form. In the desire to make the book all-inclusive, only brief generalizations are given on the various topics, so that the style is very compressed and a bit cold-blooded. The romance and adventure of scientific research is evident, but so submerged that it seldom breaks through to the surface. Non-technical writers, Floyd Gibbons, for example, using the same material, would have produced a more lively volume. It would be interesting to know whether the restrained style of the authors carries more conviction to the businessman reader than a more flamboyant one. Scientific workers will prefer it as it is, and will find it an interesting record of achievements that they may hope to emulate.

The paper used in the book does not allow the illustrations to show up to full advantage. H. W. Gillett (0)-B-

Report of the Technical Director, U. S. Government Printing Office. B. L. Wehmhoff, pages 116-128. Annual Report of the Public Printer, 1931.

The tarnishing of bronze stamping leaf is chiefly governed by the protective coating on the leaf.

Linotype metal continued to be standardized at 11½% Sb, 4 to 4½% Sn, balance Pb. An alloy of 11½% Sb, 6½% Sn, balance Pb produces sharper type faces.

Monotype metal is standard at 16.8% Sb, 7.3% Sn, balance Pb. For large type and rules one of 19% Sb, 10% Sn, balance Pb was satisfactory.

Stereotype metal remains at 13% Sb, 6½% to 7% Sn, balance Pb.

Bismuth up to 4% is neither beneficial nor detrimental in stereotype metal. With 2% Bi the plates were slightly brighter, which facilitates examination of the type face for defects.

The International Association of Electrotypers has adopted 3½% Sb, 4% Sn, balance Pb as standard electrotype backing metal.

Nickel electrotyping is now done with a solution of 7 oz./gal. of double nickel salts instead of 3 oz./gal. Covering of the wax proceeds more rapidly, double the current density is used and the time is cut some 25 to 30%.

In copper electrotyping the use of phenolsulphonic acid as addition agent produced a 42% thicker deposit on the printing surface, after plating for the same time, as when glue was used.

No trouble was met with copper sheets for half-tone work, but zinc sheets used in line work have been unsatisfactory in some cases and this problem is being studied. H. W. Gillett (0) -B-

Coöperative Research in the Iron and Steel Industry. F. N. Speller. *Engineering,* Vol. 131, June 19, 1931, page 802.

Paper read before the American Iron & Steel Institute, May 1931. See *Metals & Alloys,* Vol. 2, Sept. 1931, page 159. LFM (0)

Report of Technical Committees of the deutschen Gesellschaft für Metallkunde. (Mitteilungen der deutschen Gesellschaft für Metallkunde. Arbeiten der Fachausschüsse.) *Zeitschrift für Metallkunde,* Vol. 23, Sept. 1931, pages 266-268; Oct. 1931, pages 291-292.

Includes following reports: Spectroanalysis (Gerlach), Magnetism of Pure and Alloyed Noble Metals and Its Meaning for the Theory of Metals (Vogt), Thermoelectric Force in the System Au-Cu (Gerlach), Explanation of the Change in Susceptibility During Tensile Loading (Gerlach), Oxygen in Silver-copper Alloys (Raub). With discussion. RFM (0)

Magnetic Materials in the Year 1931. T. D. Yensen. *Yearbook American Iron & Steel Institute,* 1931, pages 452-485.

Includes discussion. The author reviews briefly the present theoretical views of the nature of ferro-magnetism and the effect of impurities; it is shown how the results from these considerations have led to the high-grade magnetic irons; their equilibrium diagrams are discussed. It is pointed out that the discrepancy between the theoretical curves for ferromagnetic materials and the early experimental curves were due to impurities and other factors which distort the crystal lattice. The development of methods of controlling these factors by means of new methods of analysis and new metallurgical processes it will be possible to produce magnetic materials to suit all requirements of practical application. 30 references. Ha (0)

The Constructor and the Science of Materials. (Konstrukteur und Werkstoffkunde.) A. Krauss. *Maschinenbau,* Vol. 10, Feb. 5, 1931, page 65.

The author makes some remarks concerning the unsuccessful use of material by the builder who does not take into consideration the possibility of residual strains in his structures. MAB (0)

The Theory of Metal Dissolution. II. III. (Zur Theorie der Metallauflösung.) M. STRAUMANIS (University of Riga). *Zeitschrift für physikalische Chemie,* Sec. A, Vol. 153, Feb. 1931, pages 107-111; Vol. 154, Sept. 1931, pages 150-158.

The difference effect cannot be interpreted as a mere resistance phenomenon. The author, therefore, stands by the theory previously developed (see *Metals & Alloys,* Vol. 2, Oct. 1931, pages 208, 217). The vectorial properties of the metal space lattice are responsible for the phenomenon discussed. The potential becomes nobler during the dissolution of metals. Part III. The author claims that the potential differences are not responsible for the anisotropic behavior of the metals in regard to their dissolution speed. Based on thermo-dynamic conclusions and on the theory of crystal growth, Straumanis concludes that the different surfaces of a metallic crystal display equal electro-chemical equilibrium potentials if the valence of the ions does not change. The differences in the dissolution velocities of the various crystal surfaces are ascribed to "included layers" of a regular arrangement which actually dominate the magnitude of the dissolution factors as the number of the elements/cm.^{2}, their resistance and the over-voltage of the cathode. EF (1)

Permanent Electric and Magnetic Moments of Crystals. F. ZWICKY. *Physical Review,* Vol. 38, Nov. 1931, pages 1772-1781.

The conditions for the existence of self-perpetuating electric moments in crystals are discussed. If these conditions are satisfied, the crystals must either show macroscopic electric moments or they will necessarily possess a definite type of a secondary structure. Certain complications, however, come in if one is dealing with metals. Experimental investigations on single crystals suggest that there are secondary lattices of very different types. Ferromagnetic crystals behave abnormally in regard to plastic deformation. Single crystals ordinarily glide along certain planes belonging to a discrete crystallographically determined set. In Fe, however, only the (111) direction is distinguished, but any plane through it may be a slip plane. This becomes comprehensible if one considers that the elementary parts of the magnetic secondary structure of iron are slightly tetragonal. Adjacent blocks are in phase only for distances less than 200A.U. making use of Bitter's estimate. Fe is therefore, in a way, more similar to an amorphous substance than to other metal crystals whose secondary structures are characterized by spacings of the order of 1μ. It is to be hoped that if Fe single crystals are annealed and distorted in a magnetic field that they also will exhibit definite crystallographic slip planes. Experiments to check this are being carried out. WAT (1)

Determination of the Melting Point of Platinum (Détermination de la température de fusion du platine). G. RIBAUD & P. MOHR. *L'Industrie électrique,* Vol. 40, Mar. 10, 1931, page 113.

By means of optic extrapolation, from the melting point of Au, the melting point of Pt was found to be at 1762° C. = 2305° K. with an error of ± 2°. Ha (1)

Silver and Its Application to Chemical Plant. DONALD McDONALD. *Journal Society Chemical Industry,* Vol. 50, Feb. 27, 1931, pages 168-178.

A very excellent review covering Ag's economic history, occurrence and metallurgy, physical and chemical properties, alloys and applications. VVK (1)

Tantalum and Niobium—Costly Metals With Growing Uses. *Chemical Trade Journal,* Vol. 88, Jan. 23, 1931, pages 77-78.

A monograph on the Mineral Industry of the British Empire and Foreign Countries dealing with Ta and Cb has been issued. Tantalite and columbite are the most prominent minerals. Methods of producing metallic Ta and Cb and the physical and chemical properties are discussed. Ta forms alloys with a number of metals including Fe, Mo and W, ferro-tantalum containing 60-70% Ta, alloys of Pt and Ta containing up to 20% Ta are highly resistant to acids or aqua regia and are harder, and less expensive, than Pt. The uses of Cb are being investigated. WHB (1)

Anisotropy in Zinc Plates. (Ueber die Anisotropie von Zinkblechen.) E. SCHMID & G. WASSERMAN. *Zeitschrift für Metallkunde,* Vol. 23, Mar. 1931, pages 87-90; *Mitteilungen der deutschen Materialprüfungsanstalten,* Sonderheft 17, 1931, pages 20-24.

The anisotropy of the yield point (0.02% and 0.20%), tensile strength, elongation, elastic modulus, thermal expansion, and specific electrical resistance in rolled Zn plates was studied. Graphs and tables record the experimental results obtained from measurements taken parallel and perpendicular to the direction of rolling (except for specific electrical resistance for which no appreciable difference could be found). The results are correlated with the rolling textures (preferred orientations) previously observed and with similar data obtained from studies on single crystals. The rolling texture of Zn is inhomogeneous. Upon the plate surface the texture is a simple fiber structure with the hexagonal axis in the direction of the plate normal. This superficial texture does not contribute to the anisotropy of the plates but diminishes it. The scattering in this orientation is considerable, reaching as high as 80°. RFM+EF (1)

Tin: Its Major Uses. *Tin,* Feb. 1931, pages 14-18.

Pointing out the importance Sn has assumed in present-day life, some commercial uses are discussed and the numerous alloys enumerated as to their analyses, applications and properties. The complete specifications of the British Engineering Standards Association for industrial uses are reproduced, and the compositions used for type metals are given. In all, 25 different alloys are treated. Ha (1)

Impurities. *Metallurgist,* Oct. 1931, pages 145-146.

Very pure metals possess quite different properties than commercially pure metals. The commercial purity of metals has been steadily increasing. Chemical methods of determining traces of impurities have not kept pace with the increased purity of metals. Spectroscopy will probably solve this difficulty. Many examples are given. VVK (1)

Gmelin's Handbuch der anorganischen Chemie. Eisen. 8th Edition. Verlag Chemie G.m.b.H., Berlin, 1931. Paper 7x10 inches, pages 657-872. Price 35 RM.

The fourth section of Part B continues the survey of the iron compounds. In the first part of this section, the Fe-C compounds are completed in dealing with iron cyanides and the balance is devoted to compounds of Fe-Si, Fe-P, Fe-Sb, and Fe-Bi. In the chapter dealing with the iron silicates, it will be of interest to note that even the FeO-SiO^2 system as it has been established by C. H. Herty and G. R. Fitterer's investigations is included. There is no need to point out that this latest section of the volume on Fe of the Gmelin series is of similar excellence to those previously published and reviewed in *Metals & Alloys,* Vol. 1, Dec. 1930, page 918; Vol. 2, Oct. 1931, page 207. G. Neuendorff (1) -B-

Effect of Impurities on Ferromagnetization. T. D. YENSEN. *Physical Review,* Vol. 38, Jan. 1932, pages 358-363.

The paper is one of the Symposium on Magnetization of the American Physical Society, Sept. 1931. The type of impurities discussed herein are those which do not fall in the ranks of the iron atoms, yet which to some extent become entangled in the iron lattice. These impurities have been studied with regard to the magnetic properties of iron in an effort to determine the magnetic properties of very pure iron. While the effect of small amounts of impurities on the saturation value is small, their effect on the initial and maximum permeabilities and on the coercive force and hysteresis loss is very great. WAT (1)

High Conductivity Oxygen-Free Copper. U. S. Metals Refining Company Booklet, Jan. 2, 1932, 10 pages.

Brief discussion of oxygen-free copper, now available as wire bars, cakes, and round billets for tubes, cast on end in water-cooled molds, and cropped. The material is specified to be free from cuprous oxide, as determined by the microscope, and is said to contain no residual deoxidant, meeting A.S.T.M. Specification B5-27. No information is given as to the process of manufacture.

The copper pipes on solidification, and so the castings are cropped instead of being brought to a level set. It is supplied in two brands, OFHC (oxygen-free high conductivity), and in the same, "selected," i.e., each bar tested to Bell Telephone Specification for submarine cable, which includes a hydrogen anneal for ½ hr. at 850° C.

Comparative tests on 0.081" diameter wire drawn from 5/16" hot-rolled rod show:

	Conductivity %		No. of 90° Bends Over 5 mm. Radius			No. of Twists in 6" Test Length			Reduction of Area %	
	Hard	Soft	Hard	Soft	H_2 Ann.	Hard	Soft	H_2 Ann.	Hard	Soft
Av. Electrolytic	98.77	101.14	6.9	13.0	0	72	89	0	55	76
Oxygen-free	98.07	100.63	10.4	18.3	10.4	130	16.3	147	80	88

No explanation is given for the lower conductivity of the oxygen-free copper.

On comparative tube drawing the OFHC copper stood 6 draws without annealing to a total cold drawing of 94% while phosphorized copper required annealing after the third draw, or 59%.

It is claimed that this copper offers more resistance to fatigue than ordinary electrolytic copper. H. W. Gillett (1)

Transformation Phenomena in the So-Called Semi-Conductors. (Umwandlungserscheinungen an sogenannten Halbleitern.) A. SCHULZE. *Zeitschrift für Metallkunde,* Vol. 23, Sept. 1931, pages 261-264.

Investigation shows that the transformation phenomena in these elements (Si, Ge, Ti, Zr) are quite different from previous conceptions. The behavior of these elements with respect to electrical conductivity and its temperature coefficient is fundamentally affected by surface layers. If these layers are not present the observed behavior is metallic. Measurements of electrical conductivity and thermal expansion in polycrystalline and monocrystalline Si, show the absence of transitions. This is confirmed by determinations of lattice structure. Ge shows a similar behavior with respect to electrical resistance. The electrical behavior of Ti indicates it to be without transformation points. The irregularities in the behavior of commercial Ti above 500° C. can be explained only on the basis of impurities. Zr shows a transformation point above 800° C. The transformation characteristics of these elements must be studied with the element in a form in which the disturbing effect of intercrystalline layers is avoided. RFM (1)

Changes of the Electromotive Force of Zinc with the Thermal Treatment. (Ueber die Aenderung der EK des Zinks bei thermischer Bearbeitung.) A. SCHÜKAREW & L. WERESCHTHAGIN (College of Charkow). *Physikalische Zeitschrift,* Vol. 32, Mar. 1, 1931, page 230.

A curve is presented revealing the successive changes of e.m.f. of a zinc test piece during an extended exposure to 200° C. There are material fluctuations with time, but the curve obtained does not correspond to a simple relationship. EF (1)

Rare Metal Thallium is Finding New Uses. *Steel,* Vol. 89, Aug. 20, 1931, page 38.

Physical and chemical properties of Tl are similar to Pb; alloys of these 2 metals, contrary to other alloys, have a higher melting point than either of the components. A Tl-Sn-Pb alloy is resistant to H_2SO_4, HNO_3 and HCl. It is used also for optical glasses with a high refractive index, and in light sensitive cells. Ha (1)

Molybdenum, the Metal That Talks. *Industry & Welding,* Vol. 3, Jan. 1932, pages 6-9, 11.

History, discovery, properties of Mo and its particular advantages in steel making and its use in radio tubes are briefly described. Ha (1)

Preparation of Pure Cerium. (La préparation du cerium pur.) *Journal du Four Electrique,* Vol. 40, Dec. 1931, page 483.

A very brief review of older methods of preparation and the description of the method used by Billy and Trombe, *Comptes Rendus,* Sept. 7, 1931. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 297. JDG (1)

On Adsorption (Ueber Adsorption). H. SCHLÜTER (University of Münster). *Zeitschrift für physikalische Chemie,* Sect. A, Vol. 153, Feb. 1931, pages 68-82.

The adsorption phenomena on silver and glass were studied in relation to temperature and pressure. EF (1)

Naval or Tobin Bronze Sheet. *Metal Stampings,* Vol. 4, Nov. 1931, page 906.

The weights/ft.^{2} from 2 ins. thickness down to gage 46 (0.0015 in.) are tabulated. Ha (2)

Tests of Zinc-Alloy Die-Cast Gears. *Metal Industry,* N. Y., Vol. 29, Mar. 1931, page 121.

Digest of paper by Robert M. Curts (New Jersey Zinc Co.) read before the Society of Automotive Engineers, Jan. 1931. Investigations showed that die-cast zinc-alloy gears are superior to brass or steel gears if not lubricated, but inferior to brass or cast iron gears if thoroughly lubricated with light mineral oil and inferior to brass gears if lubricant contains acid animal fat. The die-cast zinc-alloy gears broke under a load of 3461 lbs./in.^{2} of face as compared to 1996 lbs./in.^{2} of face for cast iron. PRK (2)

A New Beryllium Alloy. *Product Engineering,* Vol. 3, Feb. 1932, page 56.

The effect of Be in various amounts on Cu is described; an addition of 2 to 2.5% Be gives a tensile strength of more than 200,000 lbs./in.^{2} with a Brinell hardness above 400. An addition of only 1.25% Be gives a great resistance to abrasion; this percentage is also the lowest that will permit heat treatment. All Cu-Be alloys have a crystalline structure very suitable for bearing metals; tests made on bearings for German railways, indicated antifriction and wearing qualities superior to those of Sn bronzes. Physical properties for some more alloys are given. Although Cu-Be alloys at present are more expensive than Cu-Sn bronzes, their superior physical properties will make them economical for parts where corrosion resistance, wear resistance and high strength are important. Ha (2)

K. S. Seewasser, a Rustless Light Alloy. Correspondence from E. W. Ehn, Schweinfurt, Germany. *Metal Progress,* Vol. 20, Dec. 1931, pages 82-83.

The writer reports the resistance to corrosion and physical properties of an aluminum alloy with 1.4% Mn, 2.0% Mg, 0.2% Sb, and 0.7% Si. WLC (2)

Monel Metal and Nickel Alloys. T. H. Wickenden. *Paper* before the *Conference on Metals & Alloys,* Case School of Applied Science, Cleveland, Nov. 1931, 1 page. Mimeographed.

Brief historical data on Ni and Ni-Cu alloys are given and the fields of application are enumerated. Ha (2)

Use of Bismuth in Metal Forming. Walter C. Smith (Cerro de Pasco Copper Co.) *Metals & Alloys,* Vol. 2, Oct. 1931, pages 237-239.

The author discusses the composition of low melting point alloys. Use for bending copper tubing and for mounting die assemblies is described. Properties of common low melting point alloys are given with those of a new alloy, Matrix alloy, for mount dies which contains Bi 50.0%, Pb 26.7%, Sn 13.3%, Cd 10.0% and has a freezing point of 158° F. Measurement of Sound Velocities of Substances in the Solid and Liquid State. (Messung der Schallgeschwindigkeit von Stoffen im festen und geschmolzenen Zustand.) M. Reich & O. Stierstadt (University of Göttingen). *Physikalische Zeitschrift,* Vol. 32, Feb. 1, 1931, pages 124-130.

A direction finder was developed for measuring sound velocities. Due to a peculiar shape of the test specimen, the disturbances produced by the reflection of the sound waves were eliminated. Thus for the first time a method was found how to measure sound speeds and compressibilities in melts at elevated temperatures. The changes in sound velocities were determined for the following materials: water-ice, Hg, Pb, Cd, Sn and Bi. With the exception of the last metal, the sound velocities in the solid phase proved to be twice the velocity in the liquid state. In conclusion analogies to the thermal and electric conductivities are pointed out. EF (2)

Measurement of Sound Velocities of Substances in the Solid and Liquid State. (Messung der Schallgeschwindigkeit von Stoffen im festen und geschmolzenen Zustand.) O. Stierstadt (University of Göttingen) *Physikalische Zeitschrift,* Vol. 32, Apr. 15, 1931, pages 346-348.

The previously described testing method (see abstract above) was employed for determining sound velocity in the liquid and solid state on thermodynamic grounds for Cd, Hg, Pb, Sn and Bi. The data obtained are compared with the changes of electrical conductivity at the melting point and theoretical conclusions are made in regard to the compressibility and modulus of elasticity. The sound speed is regarded as related to the energy content of the metal. EF (2)

Studies on Die Castings Lead to Standard Specifications. *Iron Age,* Vol. 126, Aug. 21, 1930, pages 492-494.

Taken from report of Committee B-6 of the A.S.T.M. 21 alloys cast by 6 producers are being studied. A minor impurity in ingot metal going into Zn-base alloys has a disproportionate effect on permanence of resulting die casting. Warm, moist air, with traces of sea salt, sulphur smoke or volatile trade wastes are particularly detrimental to Zn-base die castings. Some minor dimensional changes are due to a slow alteration in microstructure of the alloys. In pure Al-Zn alloys, the β-phase in eutectic transforms into another phase when heated through 270° C. with decrease of volume and evolution of heat. Western Electric Co. and Packard Motor Co. specifications call for Zn 0.02% maximum impurities and finished castings having less than 0.005% Pb, Sn or Cd. Includes table giving the chemical compositions of Al-base die castings, also photomicrographs. VSP (2)

Aluminium-Silicon-Magnesium Casting Alloys. *Metallurgist,* Jan. 1931, pages 6-8.

An extended abstract of the paper by R. S. Archer and L. W. Kempf on the subject published as *Technical Publication* No. 352, *American Institute Mining & Metallurgical Engineers.* See *Metals & Alloys,* Vol. 1, Dec. 1930, page 898. VVK (2)

Brass Die Casting Process. *Brass World,* Vol. 27, June 1931, page 127.

Pressing die castings of brass are now manufactured in commercial quantities by the Doehler Die Casting Co. The molten metal is forced into metallic dies in a manner similar to that of making pressure die castings in Zn, Al, Sn, and Pb base alloys. Fine-grain structure and very few imperfections are claimed. Inserts of other materials required to meet specifications or unusual applications can be cast in just as in the die casting of other alloys. Physical characteristics of the alloy are: tensile strength (ultimate), 65,000-70,000 lbs./in.^{2}; yield point, 35,000-45,000; elastic limit, 20,000-30,000; elongation, 15-20% in 2 in.; reduction area, 10-20%; Brinell hardness (500 kg.), 130-140; weight/in.^{2}, 0.303 lbs.; impact strength (Izod), 20-40 ft. lbs. WHB (2)

Effects of Strain and Heat Treatment on Properties of Copper Alloys. W. C. Ellis & E. E. Schumacher. *Fuels & Furnaces,* Vol. 9, Mar. 1931, pages 289-290.

Hard drawing subsequent to heat treatment materially increases the strength without appreciably increasing the resistivity of Cu alloys containing either Ni and Si or Co and Si. Cu-Ni-Si alloys attained a maximum strength of 140,000-150,000 lbs./in.^{2} with a conductivity of 30-33% of annealed Cu. Cu-Co-Si alloys had a strength of 85,000 lbs./in.^{2} and about 50% conductivity. By heat-treating between 300° and 500° C., these properties could be further influenced. See also *Metals & Alloys,* Vol. 2, July 1931, page 126. Ha (2)

Magnetic Susceptibility of Some Binary Alloys. Francis L. Meara. *Physics,* Vol. 2, Jan. 1932, pages 33-41.

The magnetic susceptibilities of 8 series of alloys: Sn-Tl, Sb-Tl, Tl-Cd, Zn-Cd, Pb-Sb, Sn-Sb, Cd-Sb and Zn-Sb have been investigated by Gouy's method. In three series, Sb-Cd, Sb-Zn and Sn-Sb an intermetallic compound is indicated by an abrupt change in the slope of the susceptibility concentration curve. The compounds thus indicated are Sn-Sb, Cd-Sb and Zn-Sb with some evidence for the compound Sn_2Tl. There is a linear relation between the susceptibility and concentration of one of the constituents where the constituents form simple heterogeneous mixtures—a result best illustrated in the Sb-Zn series of alloys. The curve showing the magnetic susceptibility of Sn as a function of the concentration of Tl by weight is composed of two curved portions with a sharp cusp at 42% of Tl. This cusp corresponds to the eutectic of the freezing curve. With the addition of Sb to Tl it is evident that the diamagnetic susceptibility of this series of alloys decreases, passes through a minimum at about 20% by weight of Sb and then increases steadily up to a large volume of Sb. On the addition of Tl to Cd the diamagnetic susceptibility increases continuously until pure Tl is reached. There is no evidence of an abrupt change of curvature in the curve at any concentration. The addition of Zn to Cd decreases the diamagnetic susceptibility rapidly until the concentration of Cd reaches 13% by weight. In like manner the addition of Zn to Cd rapidly decreases the diamagnetic susceptibility until the alloy contains about 10% of Zn. In the Pb-Sb series the susceptibility decreases with the addition of Pb until the alloy contains about 40% Pb. For higher concentrations of Pb there is nearly a linear relation between the susceptibility and the concentration. In the Sn-Sb series between O and 51% by weight of Sb the magnetic susceptibility is a linear function of the concentration, indicating a mechanical mixture over the range. An abrupt change in the slope at 51% by weight of Sb indicates the existence of the compound SnSb. There is a peculiar rise in the curve between 85 and 95% Sb. This rise is likely due to crystallization. In the Cd-Sb series the susceptibility shows a cusp at 51% Sb corresponding to the compound CdSb. The susceptibility curve for the Zn-Sb series is characteristic of a series in which one intermetallic compound is formed and this compound forms mechanical mixture with both of the pure metals entering into the alloy. This compound is formed at 35% Zn. WAT (2)

Highly Magnetic Alloys of Nickel-Iron (Hochmagnetische Legierungen aus Nickel-Eisen). Geo. Keinath. *Archiv für Technisches Messen,* section Z913-1, 1931, page T63.

The highly magnetic alloys are distinguished from the ordinary magnetic material by their high initial permeability, high maximum permeability, and constant permeability. The best known types are: Permalloy, 78.5% Ni, 21.5% Fe; a thermically less sensitive modification is 78.5% Ni, 18% Fe, 3.5% Mo. Hipernik, 50% Ni, 50% Fe, maximum permeability 167,000. Mumetal, Phometal, Megaperm, Permenorm, Perminvar are others of more or less similar composition, the heat treatment of which is of great importance in maintaining constancy of the good magnetic qualities. Curves for coercive power, maximum magnetizability, specific resistance and magnetic losses for alternating current are given. The influence of mechanical stresses is discussed. Ha (2)

Characteristics of Alloyed Cast Iron. F. W. Shipley. *S. A. E. Preprint*, 1931, 20 pages.
The research described was undertaken for the purpose of determining some of the qualities which might be obtained in cast iron through the use of alloys. It was found that increased quality (which was reflected through higher valve-seat hardness) and improved microstructure could be obtained by additions of Ni and Cr to automotive type cylinder iron. Different combinations of these alloys were used and it was found that a ratio of 3 parts of Ni to one part of Cr gave the greatest improvement in structure in conjunction with maximum hardness. The effect of prolonged heating on 3 representative plain irons as well as on 3 Ni-Cr alloyed irons of the same base composition is shown and a marked difference is revealed in favor of the alloyed irons. See also *Metals & Alloys*, Vol. 3, Feb. 1932, page MA 31. WAT (3)

Nickel Alloy Steel Castings. A. G. Zima. *Steel Founder*, Vol. 2, Jan.-Feb. 1932, pages 6-17, 23.
The excellent physical properties of Ni steel castings as shown by ordinary static tensile tests are enhanced by the remarkable dynamic properties, i.e., resistance to impact and fatigue stresses. The properties of various alloys, as Ni, Cr, Mn, Mo, V, their effects, welding practice, method of adding the alloying elements, heat treatment, importance of proper design of castings and the miscellaneous applications are explained and the most important numerical values for all alloys given. Corrosion-Resisting Surface on New Composite Metal. *Steel*, Vol. 89, Aug. 20, 1931, pages 34-36.
A substitute for the expensive high-Cr, high-Ni steel alloys has been developed by the Industrial Welded Alloys, Inc. It is a composite metal, Plykrome, in which a corrosion-resisting steel is veneered and completely weld-bonded to a mild steel slab, and then rolled on a mill to form an integral plate or sheet. The method of doing it and applications are described. Ha (3)

Growth of Cast Iron Under Tensile Stress. Eugene Piwowarsky & Otto Bornhofen. *Foundry Trade Journal*, Vol. 45, Nov. 12, 1931, page 306.
An extended abstract of a paper on experiments which were carried out with a series of six different materials. See *Metals & Alloys*, Vol. 3, Feb. 1932, page MA31. OWE (3)

Mechanical Properties of Malleable Iron on Various Sized Test-Bars. A. L. Norbury. *Foundry Trade Journal*, Vol. 45, Sept. 17, 1931, pages 175-179, 182; Oct. 1, 1931, pages 205-208; *Giesserei-Zeitung*, Vol. 18, Nov. 1931, page 868.
A paper presented to the Pan-European Foundry Congress containing an account of transverse, tensile, bend, and elongation tests carried out on round and oblong test pieces of various sizes of blackheart malleable and of whiteheart malleable after one, two, and three annealings and with increased Mn content. Photomicrographs of the ¼-inch and ½-inch round bars from edge to centre are shown for each of the above types of malleable. The variations in mechanical properties with size of test bar are related to the microstructure. In the case of blackheart, as the size of test bar increases, the transverse strength increases very considerably while the deflection decreases. In the case of whiteheart, as the size of test bar increases, the transverse strength increases and later decreases, while the deflection progressively decreases. With increase in number of anneals the ductility of whiteheart progressively increases. The strength varies in a complicated manner, increasing on certain sizes of test bar and decreasing on others. Increase in the Mn content of whiteheart from 0.08 to 0.56% has a remarkable effect in increasing the strength and ductility of all save the smallest bars. Round bars generally give better strength and ductility figures than oblong bars of similar size. The question of standard test bars is discussed. The article is accompanied by 15 photomicrographs, 25 diagrams, and 6 tables. Ha+OWE (3)

Patina Steel. *Engineering*, Vol. 131, Feb. 6, 1931, page 191.
Briefly describes properties of steel developed by Vereinigte Stahlwerke, A.-G., of Düsseldorf, Germany. It contains 0.2-0.3% Cu and bears the trade name Patina steel. A figure is given comparing its loss in weight after immersion for 40 days in H_2SO_4 and in citric acid with the loss sustained by ordinary steel. The loss in weight for Patina steel was 15% in H_2SO_4 and 12% in citric acid compared with 47% for ordinary steel. Its mechanical properties are the same as for ordinary steel provided the Cu content does not exceed 0.5%. It can be used successfully for riveting, welding, and galvanizing. Its exact composition is not given. LFM (3)

Valves and Valve Steels and their Heat Treatment. E. F. Davis. *Fuels & Furnaces*, Vol. 9, Oct. 1931, pages 1135-1142.
Above all, the construction of valves must possess strength and lightness; exhaust valves must have resistance to scaling, corrosion and burning, ability to withstand temperatures up to 1600° F. and repeated heatings and coolings without becoming soft or brittle. Intake valves are not subjected to the severe conditions of exhaust valves. Various grades of steel are discussed and the analyses of products of several companies are given. Formerly, they usually contained 0.5-0.7% C, 0.9-1.1% Cr, 1.0-1.5% W; today the W content is as high as 16% and the steels usually have a rather complex composition. The heat treatment, hardening, quenching and drawing temperatures of several steels are indicated. Ha (3)

The Manufacture and Properties of Malleable Iron Castings. *Foundry Trade Journal*, Vol. 45, Sept. 3, 1931, pages 143-144; Sept. 10, 1931, pages 160-161.
A report of a symposium on malleable iron castings, organized by the A.F.A. and A.S.T.M., which has been abstracted elsewhere in this journal. OWE (3)

Some Physical Properties of High Speed Steel. J. V. Emmons. *Transactions American Society for Steel Treating*, Vol. 19, Feb. 1932, pages 289-332.

Hardening and Tempering of Cast Iron. Results of Investigations and Recent Applications (Härten und Anlassen von Gusseisen. Untersuchungsergebnisse und neuzeitliche Anwendung). R. Chavy. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Nov. 6, 1931, page 867.
The hardening of martensitic and austenitic cast iron has been developed, until recently, very successfully by special addition elements, particularly Ni. Several types of castings change their structure by hardening, namely hard castings with martensite-cementite structure and the following types of gray iron: (1) pearlitic castings and sorbitic castings; (2) martensitic castings; (3) gray iron with austenite-martensite structure; (4) gray iron with pure austenitic structure. Ha (3)

18-8, New Facts and New Uses. *Metal Progress*, Vol. 20, Oct. 1931, pages 43-47.
Findings of several studies reported before the Boston Convention of A. S. S. T. are discussed briefly. Applications of the alloy to turbine blades, wire products and the effect of added elements are discussed. WLC (3)

Bending Strength, Deflection and Graphite Precipitation. (Biegefestigkeit, Durchbiegung und Graphitausscheidung.) F. Brinckmann. *Die Giesserei*, Vol. 18, Dec. 18, 1931, pages 929-931.
In order to classify cast-iron the measurement of the deflection at a constant load below fracture is proposed; this "specific deflection" is shown to have a direct relation to the elasticity coefficient and to make possible a conclusion on the behavior of the material in the range of its practically occurring stresses. In connection with the nature of graphite in the Fe also the tensile strength can be related to the specific deflection. The method is explained more in detail by the field diagram of Thum and the diagram of isoflexes of Meyersberg. Ha (3)

Specifications of Hardness for Machine-Casting. (Ueber Härtevorschriften bei Maschinenguss.) F. Brinckmann & A. Nehmitz. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Nov. 27, 1931, pages 889-892.
An investigation of the tolerances laid down in the Russian specifications for machine-cast parts of machine tools showed that the differences due to different testing methods were even greater than the tolerances permitted. The conditions are discussed and it is proposed to abandon absolute figures and permit a certain leeway from an average value determined by a large number of measurements. 7 references. Ha (3)

Physical Properties of Cast Iron Rolls (Festigkeitseigenschaften gusseiserner Walzen). E. Scharffenberg. *Stahl und Eisen*, Vol. 51, Oct. 8, 1931, pages 1249-1256.
In testing cast iron, the test bars are seldom taken from the castings but are cast as special bars during the casting of the article. It is obvious that the entirely different cooling conditions between a thin test bar and such a large mass as a rolling mill roll do not allow a proper judgment of the physical properties of rolls. It, therefore, seems necessary to determine the properties of rolls direct. The properties of cast iron rolls are not uniform throughout due to the effect of the ferro-static pressure. The graphite and the structure is finer in the lower parts of the casting and, therefore, the tensile strength and hardness are higher than in the upper parts. The results on physical tests of sheet rolls are tabulated. The graphite content of the top neck was, in all cases, on the average, 0.69% higher than the graphite content of the body. The variations of the physical properties are not clearly indicated by bending strength and tensile strength but are better shown in the figures on hardness. To the same extent, the variations of the properties between the bottom neck and the body were studied and it is shown that the properties of the neck are superior to the body. Physical tests at elevated temperatures were performed to give some indications as to the behavior of the rolls at the actual rolling temperatures. In determining the hot tensile strength of a cast iron roll with passes, the tensile strength was practically constant up to 600° C., with a sharp decrease between 600° C. and 800° C. Other tests were made on necks and body of broken rolls. It is remarkable that the top neck has a much lower tensile strength than body and bottom neck and that the tensile strength decreases between 200° and 400° C. but then increases again to attain a maximum at 600° C. In testing the various sections of the body, the tensile strength-temperature curves correspond to each other with a maximum at 500° C. Relations have been established between physical properties and grain size of the rolls; the tensile strength increases with decreasing grain size. Tests on chilled iron rolls indicate that a definite relation exists between hardness of the chill and bending strength of the matrix; the bending strength decreases with increasing hardness of the chill. In determining hardness and tensile strength of plain cast iron rolls, every type of roll shows a characteristic maximum value of hardness and tensile strength. A comparison of the tensile strength of cast iron rolls with that of test bars cast separately from the same heat, indicate that no relation exists between them. GN (3)

The Properties of Stainless Steels and their Further Treatment (Die Eigenschaften der rostfreien Stähle und ihre Verarbeitung). P. Wiessner. *Dinglers Polytechnisches Journal*, Vol. 346, Sept. 1931, pages 154-156.
The writer confines himself to the technology of different corrosion resistant steels which are brought on the market by the Krupp Co., Essen. EF (3)

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Lime and Ammonia Limit Corrosion. W. T. ZIEGENHAIN. *Oil & Gas Journal*, Vol. 29, June 5, 1930, pages 35, 333.

By injecting a lime-oil slurry into the crude oil charging line to the pipe stills and ammonia gas into the vapor inlet on the towers, the Pure Oil Co., at its Smiths Bluff, Tex., refinery, has eliminated excess corrosion when topping Winkler County, West Texas, crude. The system does not call for a large investment, requires very little attention to operate and may be applied to a cracking operation as well as topping. Enough lime is injected to completely neutralize the acids formed in the oil during heating, but no trouble has been witnessed with excess lime showing up as basic sediment in the fuel oil. The only apparent effect of adding the lime in burning the resultant fuel residuum is that a fluffy deposit of calcium sulphide or calcium sulphate slowly collects on the upper side of the tubes in the convection section of the pipe stills and becomes sufficiently heavy in 10 days to necessitate its removal. This is easily done with compressed air. VVK (4)

The Corrosion of Light Alloys. *Foundry Trade Journal*, Vol. 35, Nov. 19, 1931, pages 324, 326.

A description of the methods which have been selected by a Commission of the heads of different research laboratories, acting in conjunction with the Bureau International de l'Aluminum, for measuring the corrosion of light alloys of aluminum. The necessity for stating the exact analysis of the alloy, its state and any treatment it may have received, and the condition of its service is emphasized. The dimensions of test pieces to be used in all tests are described. Other details, such as dimensions of containers, temperatures of the tests, methods of suspending test plates and correct methods for cleaning the test pieces, are described. A modified Mylius' test is described, and salt spray and immersion tests are also dealt with. OWE (4)

The First Report of the Corrosion Committee to the Iron & Steel Industrial Research Council. *Iron & Steel Institute, Advance Copy*, May 1931, 268 pages. Price 15 s.

Section A—Introduction—describes object and scope of work outlined. The object is to study the phenomena of corrosion of steel and to devise methods for reducing corrosion. Reports are to be published from time to time through the Iron and Steel Institute. Section B—Critical Discussion of the Replies to the Committee's Questionnaire—discusses the replies received from both makers and users. The concensus of opinion seemed to be that failure of steel by corrosion was generally due to lack of adequate protection rather than to defective material. A small amount of Cu was generally believed to increase corrosion resistance. Section C—Summary of the Papers and Other Information Submitted to the Committee—includes discussion of general knowledge of corrosion, behavior of steels in specific conditions, and methods for determining resistance to corrosion. Section D—The Committee's Field Tests—J. C. Hudson describes in detail the field tests planned, and the work accomplished. Careful observations and records are being made of the steels tested from the time of manufacture to the completion of the tests. The variables include rolling practice, and methods of manufacture. For these field tests 4 main exposure stations in Great Britain and 8 substations in various parts of the world to represent all conditions of temperature, humidity and air polution have been selected. The stations in England include mild industrial, very severe industrial, and severe marine conditions and heavy rainfall and possible salt air in the absence of any artificial polution. Of the substations 2 are in Lagos, Africa and offer marine and dry inland conditions respectively, one in Egypt and another in Mesopotamia offer dry hot climatic conditions and the station in Singapore offers tropical marine atmospheric conditions. The tests are divided into three parts (1) mild steel (0.2% C and 0.6% Mn) with and without Cu addition, (2) wrought iron and ingot iron, and (3) effect of process of manufacture. Part 1 is now in progress and parts 2 and 3 are in active preparation. Various protective coatings including paint and galvanizing are included. Section E—Laboratory Corrosion Tests—the development of a laboratory spray test that indicates "liability to commence rusting" is described by U. R. Evans and S. C. Britton. This method of testing was tried out on a large scale by W. H. Hatfield and H. T. Shirley. Results of a laboratory spray test and exposure tests on the same materials are given by J. C. Hudson, who found that there was fair agreement between the 2 tests. Section F—Bibliography of Copper Steels—contains 214 references dealing with the complete effects of Cu on iron and steel. Studies of Corrosion. (Etude de la Corrosion.) *L'Usine*, Vol. 40, Dec. 31, 1931, pages 29-31.

A general review of the theories of corrosion and the means to protect metals and alloys by surface treating, plating and coating. Ha (4)

Corrosion of Non-Oxidizing Steels. (Corrosion des Aciers Inoxydables.) *L'Usine*, Vol. 41, Jan. 8, 1932, page 31.

The test results of rust-proof steels of the following types: 18 Cr - 8 Ni; 10 Cr - 23 Ni, 13 Cr, pure Fe, are reproduced in diagrams which were made according to the specifications of the French Air Ministry. It was found that in order to obtain the highest corrosion resistance the surface must have a polish as fine as possible. Ha (4)

Real Progress Being Made in Treatment of Water to Prevent Corrosion. *Water Works & Sewerage*, Vol. 78, Aug. 1931, pages 217-221.

The corrosion of filtration plants and the means which have been developed to prevent it by treating the water are reviewed and their efficacy is discussed. The list of references covers the entire historical development. Ha (4)

Preliminary Report of the Copper Pipe Committee. (Voorloopig Rapport Van De Koperen Buizen Commissie.) *Water en Gas*, Vol. 15, June 12, 1931, pages 113-117; June 26, 1931, pages 125-127.

In 1927 the Society for Water Works Interests of the Netherlands appointed "The Copper Pipe Committee" which was instructed to answer the question: "Is the use of Cu pipe permissible for the distribution of drinking water?" This committee was comprised of representatives of state and city water, sanitary, municipal, chemical, bacteriological and medical departments. The work reported by Thresh in England and the German Federal Sanitary Bureau is outlined and the general conclusions drawn from these works tabulated. A survey was made to determine the amount of Cu normally absorbed by a human with different nutritive substances and was found to be of the order of 15-20 milligrams in 24 hours. The conclusion drawn was that no effect detrimental to health need be feared if the amount of Cu dissolved by water that remains in a Cu pipe for 16 hours is not greater than 3 mg./l. Tests of the same nature established a limit of ten gamma (one gamma equals 0.001 mg.) per liter for As in connection with the use of arsenical Cu as a water conductor. The Committee also investigated whether the occurrence of taste furnished a limiting value for the permissible quantity of dissolved Cu. Three types of ¼" pipe were used in the investigation: (1) electrolytic Cu (99.9%); (2) Cu containing a small amount of As (99.5% Cu, and 0.25-0.45% As); (3) tinned Cu pipe. Three types of waters were used in the tests: (1) dune water (2) river water (3) ground water; which were considered representative of the ordinary types of water handled in commercial installations. Tests of the three compositions of pipe were carried out in identically the same way, the installations being made in various pumping stations. Each installation consisted of a slightly inclined ¼" pipe made up of two pipes with a length of about 5 meters and provided with the necessary stop and drain cocks. The entire system was connected to the main supply pipe of the pumping station by a lead pipe tinned inside. In order to obtain representative conditions a continuous flow of water (50 l./hr.) was specified, the flow in each case being shut off 16 hours before the sample was withdrawn, giving a specimen which had been in contact with stagnant water for this period. The assumption that more Cu would be dissolved under stagnant than flow conditions was confirmed. Service difficulties with tinned Cu pipe result from: (1) substitution of Sn:Pb and other compositions instead of pure Sn, in which the removal of Pb by the action of water may have a more harmful effect than Cu; (2) the comparatively thin coating which is applied commercially. Preliminary tests were made under normal conditions over a period of a year, while a second group were tested in water heated to 80-90° C., the normal temperature in hot water circuits. A number of installations were made throughout the Netherlands and were tested periodically, each installation having a unit of electrolytic and one of arsenical Cu under test. Resin had been used by the manufacturers for bending the tubing and after a large amount of data had been collected, it was found that a film of resin remaining in the tubes had served as a protective coating. The film, however was subsequently removed by the flow of water exposing the Cu for attack. A third group of test sections were installed from which the resin had been removed and the results are comparable with the original tests. Waters which had remained in contact with the sections for long periods of time were used in the preparation of various vegetables in order to note the behavior of foodstuffs with contaminated waters. No discoloration or taste resulted in any of the cooking experiments. The final results varied according to the types of water handled and only very general conclusions were drawn. The fact that some As was removed was evident, but in no case was it found to exceed the permissible limit (10 gamma). Pure food laws are cited which show that in cases as high as 700 mg. $CuSO_4$ per kg. are permitted. Arsenic contents of waters from the tests are not given, but it is stated that "these are not included because the investigation showed in a satisfactory manner that in general there was no question of an approximation to the limit of permissibility." Tests are still being carried on and the results will be published at a later date. Summary of conclusions: (1) no danger results from the use of Cu pipe if the Cu content does not exceed 3 mg./l., and if the As content of the water is not higher than 10 gamma/l; (2) a maximum contamination results after a few weeks of installation and thereafter tends to reach equilibrium and dissolve Cu at a very slow rate; (3) less Cu is dissolved in hot than in cold waters; (4) the quantities of As dissolved from As-bearing Cu pipe is considerably lower than the established limiting value and may be used without objection; (5) commercial wall thicknesses are sufficient to give long life; (6) the use of tinned Cu pipe is not to be recommended pending completion of tests in progress; (7) no harmful effect on health or disagreeable taste were noted in cooking experiments conducted with contaminated water; (8) the use of Cu is considered permissible for both hot and cold water conductors from the various pumping stations at which the tests were conducted. Metal Surface Treatments. *Electrical Review*, Vol. 109, Oct. 16, 1931, page 598.

Brief description of the rust-proofing and paint-priming processes for iron and steel, Parkerizing and Bonderizing. The former consists of an immersion of parts in a solution made up of boiling water and "Parco" powder; the latter is a chemical priming process for changing the surface of iron or steel to a non-metallic coating which is an integral part of the metal. Ha (4)

Scale Prevention in Closed Feedwater Heaters. J. ALSBERG. *Railway Mechanical Engineer*, Vol. 105, Nov., 1931, pages 537-538.

The prevention of scale in locomotive feedwater heaters which also prevents, to a great extent, the heat transfer through the pipes to the water can be secured by the use of anti-foaming compounds, especially tannin. This was added in the form of briquettes from powdered extracts. An emulsion of castor oil and tannin also seems to be useful, but the tests are not yet completed. Ha (4)

Corrosion from Flue Gases. DAVID BROWNLIE. *Engineering & Boiler House Review*, Vol. 45, Oct., 1931, pages 206-207.

A continuation of the discussion begun in the Sept. 1931 issue of some methods of preventing corrosion in boilers, air heaters, and economizers. In explaining the reasons for the trouble, the recommendation is made to feed economizers and boilers with warm inlet water to minimize the stress due to temperature differences. Another remedy would be the use of absolutely non-corrodible steels. High costs often prevent the use of this course. Reduction of the S content of the coal should also be attempted. Ha (4)

The Constitution of Iron Scale. L. B. PFEIL. *Rolling Mill Journal*, Vol. 5, Aug. 1931, pages 551-554, 557-558.

The determination of the limiting composition of iron oxide in its different forms and phases is dealt with on the basis of the equilibrium diagram Fe-O-C between the percentages of 70 to 78% Fe; four phases are distinguished in this range: ferric oxide phase, the magnetic phase, Fe_3O_4, the ferrous phase, and the Fe and Fe oxide phase; each phase is discussed separately with regard to conditions of temperature and solubility. See also *Metals & Alloys*, Vol. 2, Nov. 1931, page 248. Ha (4)

Zinc Sulfate to Combat Corrosion. *Refiner*, Dec. 1931, page 87.

The Dixon Creek Oil and Refining Company has a 3500 bbl. skimming plant near Kingsmill which operates on Gray County, Texas, crude oil containing so much hydrogen sulphide that it gave constant trouble from corrosion of the steel vapor lines from the fractionating towers to the condensers. Even the admiralty tubes of the condensers were affected, and output was being lessened. Caustic having proved ineffective, zinc hydroxide was tried. To a solution of 2¼ parts of caustic in 100 parts of water, 2¾ parts of zinc sulphate is added. The solution is pumped by a Westco turbine pump to a point in the vapor line near the tower and sprayed into the vapors. Zinc sulphide is formed and settles out in the rundown tanks. Approximately 2.35 lbs. of caustic and 4.74 lbs. of zinc sulphate are required to remove 1 lb. of hydrogen sulphide. Such a quantity of the chemical is used that the test copper strip shows merely a faint peacock tinge. Instead of frequent or almost daily shut-downs, there were no shut-downs for corrosion repairs from May 10 to Sept. 10, 1931, and no signs of continued corrosion. (4)

Problems Involved in Corrosion and Metal Protection (Fragen der Korrosion und des Metallschutzes). B. SCHEIFELE. *Korrosion und Metallschutz*, Vol. 7, Aug. 1931, pages 216-217.

Review of the papers dealing with corrosion problems and presented at the General Meeting of the Verein deutscher Chemiker and the deutsche Bunsen Gesellschaft für angewandte physikalische Chemie, Vienna, May 1931. EF (4)

The Resistance to Corrosion by Sea-Water of Cadmium Coatings on Iron and Light Metals. (Seewasserbeständigkeit galvanischen Ueberzüge auf Eisen und Leichtmetallen.) E. K. O. SCHMIDT. *Zeitschrift für Flugtechnik und Motorluftschiffahrt*, Vol. 22, Mar. 14, 1931, pages 141-147.

The investigation was undertaken in order to ascertain the resistance to corrosion by sea-water of cadmium coatings, deposited on iron and light metals, by the galvanizing process. The conclusion of these tests as regards light metals, are the following: cadmium on Duralumin and Lautal shows, in spite of some difficulties of applications encountered by plating, a very good protective capacity. This protective capacity is much higher than the one ascertained for rubber coatings. On the contrary, for Elektron, cadmium plating did not give satisfactory results. WHB (4)

Oxidation of Some Copper Alloys (Die Oxydation einiger Kupferlegierungen). J. ST. DUNN. *Korrosion und Metallschutz*, Vol. 7, Oct. 1931, page 250.

Discussion on a paper presented before the Institute of Metals, Zurich, Sept. 1931. EF (4)

Corrosion Research and Production of Brines for Refrigeration Purposes (Korrosionsforschung und Kühlsolefabrikation). J. WIESENT. *Zeitschrift für die gesamte Kälte-Industrie*, Vol. 38, Feb. 1931, pages 21-23.

The Equilibrium Diagram of the Copper-rich Copper-Silver Alloys. Cyril Stanley Smith & W. Earl Lindlief (American Brass Co.). *American Institute Mining & Metallurgical Engineers, Technical Publication* No. 433, Sept. 1931, 16 pages.

The liquidus was determined from cooling curves. The solidus and limit of solid solubility of Ag in Cu were determined by microscopic examination of heat treated alloys. The solid solubility curve obtained was in good agreement with the curves recently published by Stockdale and by Ageew, Hansen and Sachs. Attempts to produce age hardening, which would be expected to result from the change in solubility with temperature, were unsuccessful. Previous work on the Cu-rich portion of the diagram is critically reviewed. 22 references. JLG (5a)

On the Detection of Sulphur in Steel Specimens by the Printing Method (Ueber den Nachweis des Schwefels in Stahlschliffen durch das Abdruckverfahren). H. J. van Royen & E. Ammermann. *Archiv für Eisenhüttenwesen,* Vol. 4, Mar. 1931, pages 435-438; *Stahl und Eisen,* Vol. 51, Apr. 9, 1931, pages 462-463.

The investigation was undertaken to check the results of M. Niessner (*Archiv für Eisenhüttenwesen,* Vol. 3, 1929, pages 157-161). Niessner claimed to have proven that the yellow color of the sublimate print when subjected to Feigl's iodine-acid reaction indicates the S. Since the authors are of the opinion that the method of Niessner does not prove the absence of P, they developed a new method which strictly indicates only the S present by a color which is independent of the amount of S in the steel. 2 solutions are necessary. Solution 1 contains in one liter, 25 g. cadmium acetate + 200 cc. 80% acetic acid; to this solution is added a solution of 50 cc. H_2SO_4 (specific gravity 1.84) in 950 cc. H_2O. Solution 2 contains 120 g. $CuSO_4$ + 880 cc. H_2O + 120 cc. H_2SO_4 (1.84). The specimen to be tested is pressed upon gelatine paper which has been treated with solution 1 for 2-4 mins. Yellow cadmium acetate is precipitated and transformed to the dark brown to black Cu_2S in solution 2 (2-3 mins.). The prints are then washed and dried. P is not indicated by this method. GN (5a)

Austenite-Martensite Transformation and Theories of Steel Hardening. (Austenit-Martensit-Umwandlung und Stahlhärtungstheorie). S. Steinberg. *Archiv für Eisenhüttenwesen,* Vol. 5, Jan. 1932, pages 383-385.

Report of the Uraler Institut für Metallforschung. Through dilatometric and metallographical investigation on C steels, containing 0.7, 0.98 and 1.32% C, it was determined that supercooled austenite is transformed at temperatures from 200 to 350° C., more or less gradually into martensite. Stability of supercooled austenite (at constant temperature) increases rapidly with temperature drop and higher C content. Independent of the rate of cooling, austenite is converted chiefly into martensite upon further cooling to room temperature. Transformation temperature drops with a rise in C content. From magnetic measurements, less residual austenite was present in the hardened steels of heterogeneous structure, after rapid cooling than after slow cooling. An exception to this was in the case of steel with 1.60% C, of a homogeneous structure, in which more austenite was present after slow cooling. Hanemann's Phase Theory & Tammann & Scheil's Tension Theory of steel hardening are discussed on basis of experimental results. Results are not in accord with Hanemann's Phase Theory. Tension forces are set up by martensite crystals in the surrounding austenite. These forces in tension are not uniformly distributed; they are greater in direction of crystallographical surfaces. Perpendicular to these surfaces compression forces are produced which arrest austenite transformation. In this way origin of peculiar martensite needle structure may be explained, all in accord with the Tension Theory of steel hardening. GN + DTR (5a)

Dilatometric Anomalies in Soft Carbon Steels. (Étude sur des aciers ordinaires doux et extra-doux notamment au point de vue des anomalies dilatométriques.) J. Seigle. *Congrès International des Mines, de la Metallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 365-383; *Metallbörse,* Vol. 20, Aug. 23, 1930, page 1885.

The position of Ar_3 and Ac_3 and the spread between the 2 points was studied dilatometrically on low carbon steels, Armco, wrought iron, etc. in a number of cases after decarburization by heating in hydrogen. The data are shown in 28 figures. The results are explainable on the basis of the effect of phosphorus and other impurities on the position of the α - γ transformation. Deformation at high temperatures also seems to have an effect. See also *Metals & Alloys,* Vol. 1, Dec. 1930, page 907. HWG + WHB (5a)

Plane Polarized Light in the Microscopic Investigation of Ores and Metals. Freleigh Fitz Osborne. *Canadian Mining and Metallurgical Bulletin* No. 237, Jan. 1932, pages 1-13.

A general discussion. AHE (5a)

Microstructure of Pig and Cast Iron. (Gefüge-Ausbildung von Roh-und Gusseisen.) H. Pinsl. *Giesserei-Zeitung,* Vol. 27, Aug. 15, 1930, pages 436-447.

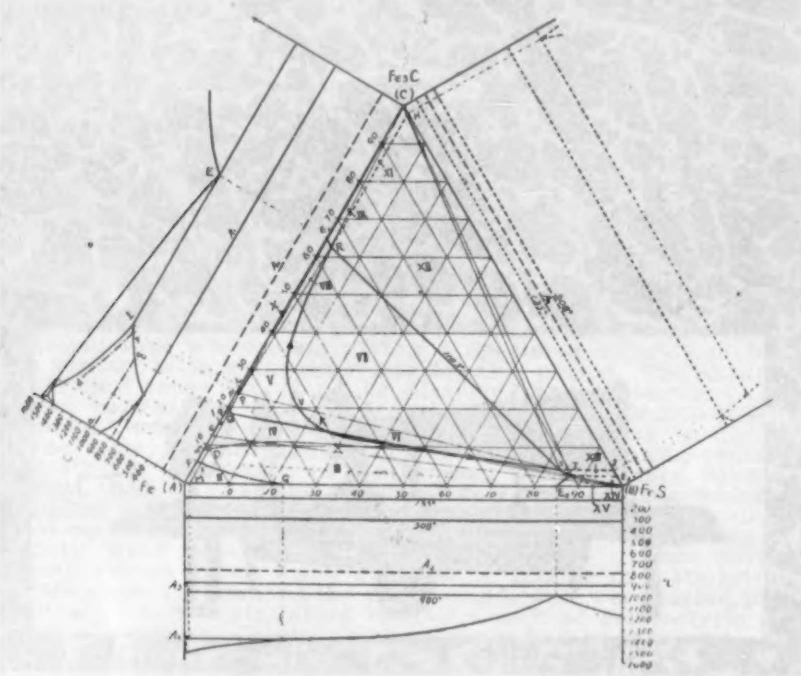
A series of 133 photomicrographs showing the various structures of P, graphite, combined C and slag in pig Fe and cast Fe. (5a)

Dilatometric Analysis and the Quality of Metallurgical Products (L'analyse dilatométrique et la qualité des produits métallurgiques). Pierre Chevenard. *Revue de Métallurgie,* Vol. 28, Oct. 1931, pages 565-569.

Basic principles and the results obtained with dilatometric analysis are described. All physico-chemical transformations, many structural changes and modifications due to recrystallization, disappearance of the internal stresses are sharply shown on dilatometric curves. Whatever might be their intensity, rapidity or slowness, they can be ascertained with certainty and subjected to quantitative study by simple and convenient technique. JDG (5a)

On the Equilibrium Diagram of the Fe-Fe_3C-FeS System. Tomo-o Sato. *Tetsu to Hagane*, Vol. 17, Nov. 1931, pages 1126-1149.

By utilizing thermal and microscopic analyses the equilibrium diagram of the Fe-Fe_3C-FeS system was thoroughly investigated. Electrolytic iron, pure white pig iron and pure FeS were melted together in a Tammann furnace, under a cover of fused glass in which Na_2CO_3 added in a proportion of 6 : 1 to protect the oxidation of the melt. 75 alloys, 0-62.1% Fe_3C and 0-89.0% FeS, thus prepared were subjected to the thermal analysis. Fig. 1 shows the projectional diagram of this whole system, to which 3 binary equilibrium diagrams are attached. In this system, there exist two liquid phases, m_1 and m_2, in a certain composition range, which is evidently proved by two layers in the solidified mass. The under layer, m_1, consists of the phase rich in Fe and Fe_3C, while upper layer, m_2, of that rich in FeS. By a monotectic reaction, $m_1 \rightleftarrows m_2 \pm \gamma$, these 2 liquid phases change their mutual solubility, and then a monotecto-eutectic reaction, $m_1 \rightleftarrows m_2 + \gamma + Fe_3C$, at 1,103° take place. At last, by a ternary eutectic reaction, $m \rightleftarrows \gamma + FeS + Fe_3C$, at 968° the solidification finishes in cooling. The A_4, A_3, A_2, and A_1 critical points of iron are almost unaffected by addition of S, showing that the S is only very slightly soluble in the solid



iron. The binary equilibrium diagram of Fe-FeS system obtained by the present investigation agrees with those of the former investigators; the A_4, A_3, and A_2 critical points of the alloys were determined experimentally in the present investigation. From the experimental results the isothermal diagrams, section diagrams and projection diagram of the space model of this ternary system were constructed. A qualitative binary diagram of Fe_3C-FeS system was deduced from the diagrams of the ternary system. TS (5a)

Recent Results on the Migration Phenomena in Crystallized Solid Bodies. (Neuere Ergebnisse über Wanderungsvorgänge in kristallisierten Festkörpern.) A. Smekal. *Zeitschrift für physikalische Chemie*, Bodenstein Festband, 1931, pages 442-452.

The theoretical discussion takes the following steps: Temperature laws and transference ratios of solid ion conductors. Permanent conductivity and "true conductivity." Problem of "best conducting" group of matter. Foreign diffusion and loose structure of true crystals. EF (5a)

Melting Diagrams of the Systems Zirconium-Dioxide—Beryllium oxide. (Schmelzdiagramme des Systems Zirkondioxyd—Berylliumoxyd.) O. Ruff, F. Ebert & H. V. Wartenberg. *Zeitschrift anorganische und allgemeine Chemie*, Vol. 196, Mar. 5, 1931, pages 335-336.

Tests employing X-ray methods were made whereby a compound $ZrCaO_3$ with a melting temperature of 2350°C. could be determined with certainty. Ha (5a)

A Thermodynamic Study of the Iron-Carbon System in the Solid and Liquid States I. II. Yap, Chu-Phay. *Transactions Faraday Society*, Vol. 27, Dec. 1931, pages 777-790, 790-797.

The application of the thermodynamic laws of the depression of the freezing point to the iron carbon system indicates that the heat of fusion of γ iron is 66.4 cal./g. and heat of transition of $\gamma \rightarrow \delta$ iron is 2.2 cal./g. and of α-γ change is 5.5 ± 0.2 cal./g.

The heat of solution of Fe_3 C in austenite is about 5700 cal./mol. The solute in austenite is carbon at temperatures above 1020° C and below it is Fe_3C. Considerable discussion on the interpretation of results obtained by thermodynamic methods is given. PRK (5a)

A New Mono-Metallic Disturbance with Compensation Effect by Thermal Anistropy (Eine neue monometallische Unruhe mit Kompensationswirkung durch thermische Anistropie). R. Straumann. *Zeitschrift für Instrumentenkunde*, Vol. 51, July 1931, pages 379-380.

Refers to a lecture delivered at the Meeting of the Gesellschaft für Zeitmesskunde und Uhrentechnik, Kassel. The compensation effect of the new disturbance is accomplished by rolling the material in a certain direction, resulting in the phenomenon of thermal anisotropy, i.e., the materials show materially different coefficients of thermal expansion towards different directions. The following materials are considered: elinvar, single crystals of metals, Zn-Cu alloys with 3-5% Cu and Zn-Cd alloys containing 20% Cd. Related problems, such as degree of rolling, heat treatment, aging phenomena, X-ray structure are briefly dealt with. EF (5a)

Contribution to the Binary Systems of Aluminum and Cadmium, Lead and Bismuth. (Zur Kenntnis der Zweistoffsysteme des Aluminiums mit Cadmium, Blei und Wismuth.) M. Hansen & B. Blumenthal. *Metallwirtschaft*, Vol. 10, Dec. 4, 1931, pages 925-927.

Contains 8 references. Slight solubility of Cd, Pb and Bi in liquid Al was proved by determination of cooling curves with Pt-Pt Rh thermocouple. The Al used was 99.91% pure. The maximum reduction in melting point produced by Cd was 11° at 5% Cd, by Pb 1.5° and by Bi 3.5° C. Al was practically insoluble in molten Cd, Pb and Bi. The solubility of Cd in solid Al is less than 0.97% at 550° C. and decreases at lower temperature. The hardness of Al-Cd alloys can be increased about 40% by heat treatment. CEM (5a)

Pure Tin has no Allotropy. Correspondence from K. Honda, Sendai, Japan. *Metal Progress*, Vol. 20, Nov. 1931, page 80.

The writer reports work on Cd-Sn equilibrium showing no transformation in pure Sn. WLC (5a)

Properties of Atomic Hydrogen. III. Mercury Hydrides. (Zur Kenntnis des Verhaltens von atomarem Wasserstoff. III. Zur Kenntnis des Quecksilber-hydrids.) A. Klemenc & F. Patat. *Zeitschrift für physikalische Chemie*, Sec. A, Vol. 158, Dec. 1931, pages 65-77.

The reactions in the system Hg-H_2 occurring under the influence of the resonance radiation are due to the atomic hydrogen. EF (5a)

Remarks on Drawing Equilibrium Diagrams. (Remarques sur le trace des diagrammes d'equilibre.) L. Grenet. *Aciers Speciaux Metaux et Alliages*, Vol. 6, Jan. 1931, pages 2-10; July 1931, pages 319-332.

This thesis in two articles is a critical review of methods for obtaining equilibrium diagrams. The author advocates the use of thermodynamics along with the observed facts when the equilibrium diagram of a system is to be finally drawn. Based on his theoretical consideration, the author advances the statement that all the existing equilibrium diagrams may have to be radically changed in order to include all the thermodynamical factors of the system. The Ternary System Iron-Chromium-Nickel. (Das Dreistoff-system Eisen-Chrom-Nickel.) W. Jellinghaus. *Stahl und Eisen*, Vol. 51, May 21, 1931, pages 651-652.

A review of the recent work on the equilibrium diagram of the system Fe-Cr-Ni, as carried out at the Kaiser Wilhelm Institut für Eisenforschung in Düsseldorf. Ha (5a)

The Constitution of Austenite and of The Solid Solution of Carbon in δ Iron and of the Liquid Solution in Equilibrium with these, Examined Thermodynamically. F. H. Jeffery. *Transactions Faraday Society*, Vol. 27, Dec. 1931, pages 751-755.

Austenite is a solid solution of monatomic carbon in δ iron and not of Fe_3C in iron. The liquid phases in equilibrium with the solid solutions of δ iron and of austenite consist of monatomic carbon molecules in monatomic iron molecules. The solid solution derived from δ iron is monatomic molecules of carbon in monatomic molecules of δ iron. PRK (5a)

The Formation and External Form of Segregates from Metallic Solid Solutions. (Ueber die Entstehung und Ausbildungsform von Segregation in metallischen Mischkristallen.) H. Hanemann & O. Schröder. *Zeitschrift für Metallkunde*, Vol. 23, Oct. 1931, pages 269-273, 297-300.

It is assumed that the formation of segregates (precipitates) from super-saturated solid solutions is a result of a diffusion of atoms in columns along preferred crystalline directions characterized by close packing of atoms and maximum separation from similar columns, and by the presence of only one type of atom in the diffusing column. This type of diffusion is called "perfusion." If diffusion cannot take place in this way (as in solid solutions of the substitutional type) the segregation is very slow and leads to the formation of a fine structure, as in duralumin, rather than a gross structure, as in the steels and brasses. The external form taken by the segregate is determined by the crystallographic directions selected for perfusion. The growth direction of the segregate is most probably half-way between two such perfusion directions. It is stated that ferrite segregates from austenite (in the Fe-C system) upon both the octahedral and cube planes in the austenite, and that the α-phase segregates from the β-phase in the Cu-Zn system upon the octahedral planes in the β-phase, phenomena which may be understood upon the theory elucidated. The geometry of the traces of segregate needles or plates upon a surface of polish is discussed. RFM (5a)

Effect of Heat Treatment upon Ferrite Banding in Steel. W. E. Harvey & Bradley Stoughton. *Fuels & Furnaces*, Vol. 9, Oct. 1931, pages 1151-1152, 1162.

Paper read before the American Society for Steel Treating, Sept. 1931. See *Metals & Alloys*, Vol. 3, Jan. 1932, page MA 14. MS (5a)

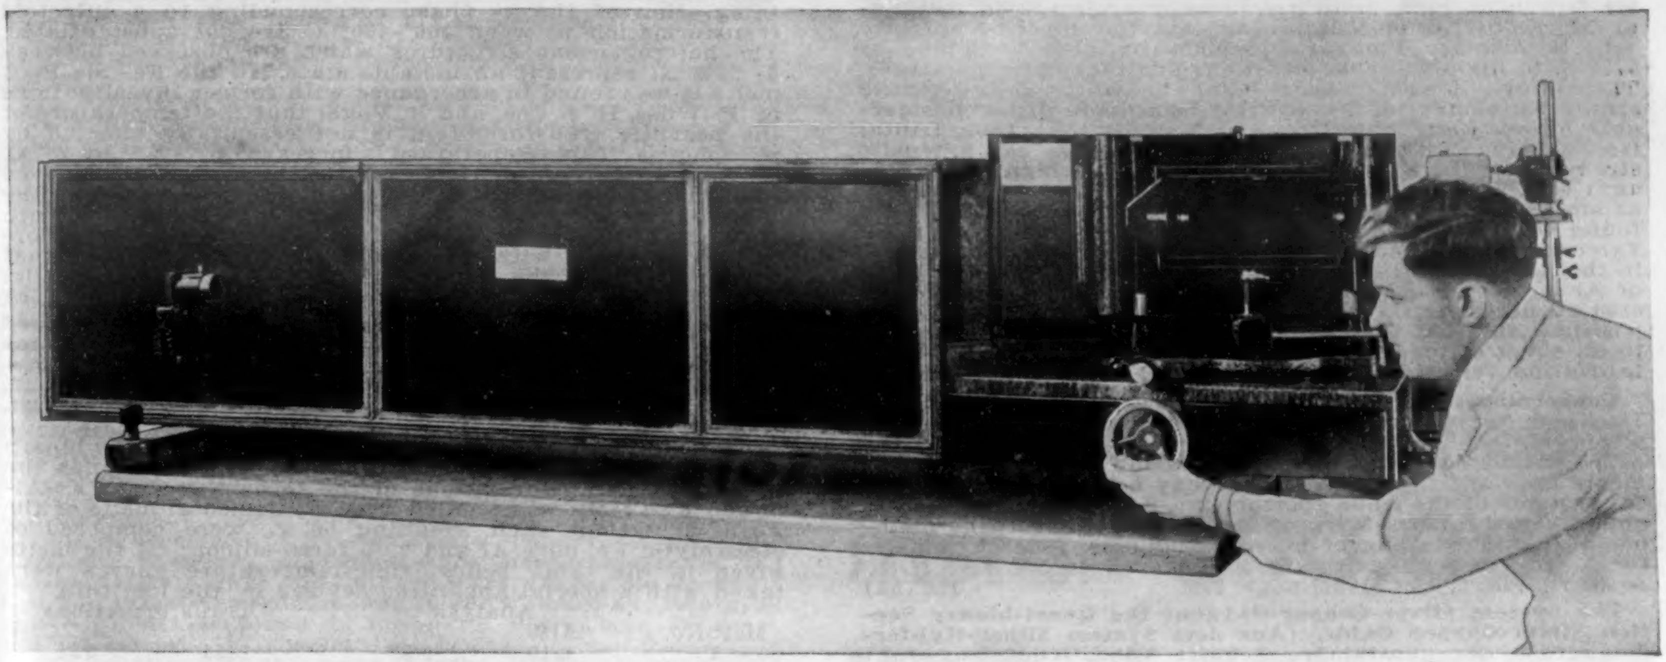
The Equilibrium Diagram of Copper-Gold Alloys. (Das Zustandsdiagramm der Kupfer-Gold-Legierungen.) G. Grube, G. Schönmann, F. Vaupel & W. Weber. *Zeitschrift für anorganische und allgemeine Chemie*, Vol. 201, No. 1, 1931, pages 41-47.

Copper-gold alloys crystallize from their melts in a continuous series of solid solutions which show at 59.5 atomic % a minimum of the solidification temperature at 884° C. The electric resistance and the thermal expansion of the alloys was measured from room temperature to 460° C., and the conversion points determined. In the β-solid solutions the ordered distribution of the crystal Cu_3Au was found, in the γ-solid solution the crystal CuAu. The compound Au_3Cu does not exist in the temperature range investigated. The course of the temperature-resistance curves permitted the conclusion that in heating the alloys the transformation occurs in 2 stages; the temperature limits for both stages were determined. Metallographic and micrographic investigation of the alloys confirm the results shown by the equilibrium diagram. Ha (5a)

Automatic Polishing of Metal Specimens. R. G. Guthrie & J. A. Comstock. *Metal Progress*, Vol. 20, Dec. 1931, pages 59-63.

The authors discuss the progress in preparation of metallographic specimens and emphasize its importance in the production of fine micrographs. The automatic equipment in use in their laboratories is described. Uniform surfaces free from scratches or torn out inclusions are produced by automatic polishing. WLC (5a)

B & L Announces . . . The Large Littrow Type Spectrograph



The new B & L Quartz Spectrograph, Littrow Type. Note the compactness and rigid construction. Length over all 8′ 10″. A completely replaceable set of optical parts, made of flint glass of refractive index 1.625, is offered for those whose work involves much use of the long wave-length portion of the spectrum.

THE announcement of the new B & L Spectrograph is of interest to every metallurgist. This instrument permits effective, accurate spectral analysis of alloy steels, tungsten carbide alloys, stellite and all other materials yielding spectra in which the lines are crowded. This is due to the high resolution, great linear dispersion and fine optical performance of this Spectrograph by which the most complex spectra are effectively resolved and dispersed. Plates show exceptional definition and complete freedom from fog and reflection.

Ease and convenience of operation distinguish this new instrument. The operator makes all adjustments that must be made in use quickly and easily from this convenient position.

ENGINEERING SCHOOLS

This instrument is an excellent medium for research work, for instruction in the principles of spectrum analysis and for practical work in qualitative and quantitative analysis of all metals and alloys. Send the coupon for full descriptive information.

The laboratory with this new instrument is equipped to handle *any* spectro-analytical problem that may arise.

Careful designing has made the operation of this new instrument easy and rapid. All adjustments that must be made in use can be made by the operator from his position at the plate holder end. The permanently aligned, rigidly mounted illuminating system is likewise a timesaver.

Routine analysis and control work, both qualitative and quantitative, is made easier, more economical and decidedly more valuable and effective by this new B & L Quartz Spectrograph.

Research men, control men, production men and plant executives will find the full information on this remarkable new instrument of vital interest.

A Study of Crystallization at Pressures up to 20,000 Atmospheres. (Kristallisationsversuche bei Drucken bis zu 20,000 Atmosphären.) G. Welter. *Zeitschrift für Metallkunde*, Vol. 23, Sept. 1931, pages 255-260.

Includes discussion. Since defects chiefly in the nature of voids are usually in metal castings, diminishing the physical properties, Welter points out that freezing metal melts under pressure should effect an improvement. 5 Al alloys, designated "German alloy," "American alloy," "Silumin, unmodified," "Cetal," "Lautal," were frozen at pressures from 1 to 20,000 atmospheres, the physical properties determined and the metallographic structure studied. In every case the ingot frozen at pressures from 12,000-20,000 atmosphere showed a density greater than that frozen at 1 atmosphere. The high pressure also caused a grain refinement quite separate from any cooling effect. "Silumin" (Al-Si with 13% Si) frozen at high pressures showed a change in metallographic constitution, suggesting that the effect of pressure was to displace the eutectic normally at 12% Si and at 575° C. to higher Si concentrations and higher temperatures. The alloys frozen under high pressure show tensile strengths, elongations, and Brinell hardness often considerably higher than those frozen at 1 atmosphere, thus, Lautal frozen between 12,000 and 20,000 atmosphere has a tensile strength (average) of 34,000 lbs./in.², an elongation (average) of 15%, and a Brinell hardness (average) of 73, whereas similar values for the alloy frozen at 1 atmosphere were found to be 19,000 lbs./in.², 2.1%, and 49. In discussion G. Tammann points out that the displacement of the eutectic in the Al-Si system is not surprising, since the melting point of Al is increased by increased pressure and that of Si decreased necessitating a horizontal shift in the eutectic composition; and that the change in grain size must be ascribed to an effect of pressure upon the nuclei formation and crystallization velocity. RFM (5a)

Concerning the Art of Metallography. Francis F. Lucas. *Heat Treating & Forging*, Vol. 17, July 1931, pages 668-671; Aug. 1931, pages 783-784, 813-814, 817.

The article describes the types and the function of instruments used and the results which may be obtained. The optical systems of the Abbe apertometer, microscope and testing objectives, the Zeiss-Martens metallurgical outfit, the methods of etching, taking of micrographs and "reading" of pictures are thoroughly explained. 8 references. The System Silver-Copper-Oxygen: the Quasi-binary Section Silver-Copper Oxide. (Aus dem System Silber-Kupfer-Sauerstoff: der quasibinäre Schnitt Silber-Kupfer-oxydul.) J. A. A. Leroux & K. W. Fröhlich. *Zeitschrift für Metallkunde*, Vol. 23, Sept. 1931, pages 250-254.

The results of thermal analytical and micrographical studies of the quasi-binary system Ag-Cu_2O are given. The system is monotectic eutectiferous. The melting point of Cu_2O (approx. 1235° C.) is depressed to 1134° C. by 7% Ag, at which temperature and composition 2 liquid phases result extending to approximately 82%. The eutectic composition is 98% Ag and the eutectic temperature 941° C., the melting point of pure Ag 963° C. Cu_2O dissolves 2.7% Ag in solid solution at 1134° C., the solubility decreasing with decreasing temperature; the solid solubility of Cu_2O in Ag is approximately 0.3% at 941° C. Cupric oxide could not be detected as a constituent, contrary to the findings of Vogel and Pocher, though in Cu_2O-rich melts Cu as a Cu-Ag eutectic was detected. Tentative explanations for these facts are advanced. RFM (5a)

Micro-Analytical Methods. M. E. Long & G. W. Leeper. *Chemical Engineering & Mining Review*, Vol. 24, Dec. 5, 1931, pages 99-101.

A brief review of macro and micro- analysis methods. WHB (5a)

The Alloys of Iron and Manganese. V. N. Krivobok. *Heat Treating & Forging*, Vol. 16, Dec. 1930, pages 1538-1540.

A report on the heat treatment and metallography of the alloys of the 2 metals. The microstructure is discussed in 6 groups: Mn content from 0 to 1.4%; from 1.4 to 2%; from 2 to 16%; from 16 to 30%; from 30 to 60%; from 60 to 100%. The behavior of each group is described and microphotographs of 12 specimens containing from 1.9 to 75% Mn are reproduced. Ha (5a)

Effect of Normalizing on the Grain Structure and Physical Properties of Automobile Sheet Steel. William F. McGarrity & H. V. Anderson (Lehigh University). *American Society for Steel Treating, Preprint* No. 31, 1931, 14 pages.

Paper read and discussed before the Boston Convention of the Society in Sept. 1931. The authors report a study of normalizing commercial automobile sheets at various temperatures from 1400° to 1880° F. X-ray diffraction methods and microstructural examination were correlated with Erichsen tests for workability. The effect of heating time on grain size is discussed. Temperature of 1700°-1750° F. was found to give the best structure and Erichsen values. See also *Metals & Alloys*, Vol. 3, Feb. 1932, page MA 41. WLC (5a)

On the Formation of Acicular Ferrite in Tungsten Steels. Takejiro Murakami & Shuzo Takeda. *Technology Reports of the Tohoku Imperial University*, Vol. 10, Dec. 1931, pages 267-294.

By dilatometric measurement during cooling under various conditions, the critical points of tungsten steels were determined, and the effects of the change of composition, the maximum heating temperature and the rate of cooling on the critical points were thoroughly investigated. From the microscopic investigation, it was confirmed that acicular ferrite separates at a lowered critical point below 500° C., resulting in the characteristic acicular structure. As the cooling rate increases, the acicular structure gradually resembles martensite, which is formed by quenching, but no distinct boundary can be drawn between the two, the transition being continuous. The change of hardness or electric resistance with the cooling rate is also continuous. From these results the mechanism of the formation of acicular ferrite in tungsten steels were satisfactorily explained by Tammann's theory, assuming the crystallization curve for the respective phases, i.e., ferrite, carbide and martensite. TM (5a)

Differential Thermal Analysis of Iron Alloys. (Thermische Differentialanalyse von Eisenlegierungen.) E. Söhnchen & H. Nipper. *Stahl und Eisen*, Vol. 51, Dec. 31, 1931, pages 1618-1620.

Report from the Foundry Institute of the Technische Hochschule Aachen. The paper briefly describes first a new simple apparatus for taking thermal differential curves and then reports the results of investigations which were carried on on alloys of Fe-Ni, Fe-Si - P - C and Fe - Si - Ni- C. In the system Fe-Ni the data on the course of the γ-transformation and on the range and nature of the heterogeneous field ($\alpha \rightarrow \gamma$-phase) are still very contradictory, but the authors' results show, in accordance with those of former investigations by T. Kasé, K. Honda & S. Miura, P. Chevenard, and A. Merz, that the A''' transformation gradually decreases with increasing content of nickel. The results by F. Osmond, and D. Hanson & H. E. Hanson who found a disintegration of the γ- phase corresponding to a eutectoid transformation between 300°-400° C are not substantiated. The heterogeneous structures which are observed between 5- 35% Ni represent an instable state. In the Fe- Si- P- C melts it was found in accordance with former investigations by F. Wüst, H. J. Coe, and R. Vogel that the temperature of the pearlitic transformation is not essentially affected by phosphorus. This temperature is increased by 1% P by 25° C. No further increase of the pearlitic temperature is observed with higher contents of P and in the presence of Si. In the system Fe- Ni- Si- C melts with 1% and 2% Si and with either 1.75% or 3.5% Ni were investigated. The A' transformation increases with increasing content of Si, but so that the A' curve for the higher Ni content is running parallel below that of the lower Ni content. 14 references. GN (5a)

Two Examples of Ternary Systems of Iron with Closed γ-Field (Zwei Beispiele von Dreistoffsystemen des Eisens mit geschlossenem γ-Raum). F. Wever & A. Heinzel. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 13, No. 16, Report 186, 1931, pages 193-197; *Stahl und Eisen*, Vol. 51, Oct. 1, 1931, pages 1237-1238.

The simultaneous effect of 2 alloying elements, the binary system of which with iron shows a closed γ-field, upon the polymorphic transformations of the ternary systems Fe-Al-Si and Fe-Cr-Mo was studied. The experimental melts of the Fe-Al-Si system, each weighing 50 g., were composed of electrolytic Fe, pure Al and 93% ferro-silicon. Of the melts given in the table below, time-temperature curves were taken with a special apparatus devised by the institute.

	Analysis		Transformations	
Melt No.	Al%	Si%	A_4 °C	A_3 °C
1	0.19	0.58	1351	952
2	0.31	0.93	1300	1014
4	0.43	1.21	....	....
5	0.50	1.33	....	....
18	0.49	1.60	....	....
6	0.16	0.25	1385	905
7	0.44	0.53	1326	976
8	0.71	0.65	1270	1048
9	0.78	0.64	....	....
10	0.91	0.85	....	....
19	0.90	0.98	....	....
11	0.44	0.19	1350	935
12	0.48	0.13	1347	948
13	0.64	0.23	1275	1030
14	0.74	0.24	1303	1000
15	0.93	0.36	1235	....
16	0.99	0.41	....	....
17	1.14	0.44	....	....

The results show that the stability field of the face-centered γ-solid solutions is closed by a ruled surface of straight line isotherms which connect the boundary curves of the 2 binary systems. The simultaneous effect of the 2 elements is a strictly additive one and can be calculated by means of a simple linear equation. The diagram is shown. The melts for the system Fe-Cr-Mo were made of electrolytic Fe, Cr containing 99.2% Cr, 0.01% C and pure Mo powder and investigated by the same method as the Fe-Al-Si melts. The results are as follows:

	Analysis		Transformations	
Melt No.	% Cr	% Mo	A_4 °C	A_3 °C
1	0.94	1.31	1329	928
2	1.16	1.72	1292	948
3	1.33	2.40	1221	977
4	1.62	2.39	1178	983
5	1.67	3.04	....	...
6	1.94	3.47	....	...
7	1.11	0.47	1372	896

13	4.94	2.63	....	...
14	2.63	0.57	1353	870
15	3.39	0.79	1327	852
16	4.25	1.16	1300	851
17	5.71	1.47	1243	870
18	7.37	1.53	....	...
19	8.08	1.84	....	...

The equilibrium field of the ternary Fe-Cr-Mo-γ-solid solutions is shown. In both of the binary systems FeCr and Fe-Mo the decerase of the A_4 transformation is more pronounced than the corresponding increase of A_3. The vertex curve of the γ-field, therefore, ascends on the Fe-Cr side from 925° C. at 14% Cr to 1125° C. at 2.5% Mo on the Fe-Mo side. The boundary face of the equilibrium space of the γ-field is bent and, therefore, the isotherms are also bent so that a simple calculation of the simultaneous effect of the 2 elements is not possible. GN (5a)

Problems in the Foundry. Metallography and Foundry. (Probleme im Giessereiwesen. Metallographie und Giesserei.) A. Portevin. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Dec. 4, 1931, pages 921-922.

The problems still to be investigated in the production of good castings are reviewed; although metallography has aided in producing a chemically and physically uniform material other factors such as segregation, pipes, fluidity, etc., remain to be studied. Ha (5a)

An X-Ray Study of the Alloys of Silver with Bismuth, Antimony and Arsenic. Part II. S. J. Broderick & W. F. Ehret. *Journal of Physical Chemistry*, Vol. 35, Nov. 1931, pages 3322-3329.

X-ray examination of the Ag-As system supports the thermal diagram of Heike and Leroux in the main. The solubility of As in Ag is approximately 5%, the lattice parameter of the metal being increased from 4.076 A.U. to 4.080 A.U. for the saturated phase. The solubility of Ag in solid As is practically nil. A β phase, containing approximately 7.5% As, appears at higher temperatures, the structure being hexagonal close-packed with an axial ratio of 1.633. The side of the elementary parallelopiped is 2.891 A.U. and the height 4.722 A.U. A discussion of the relationship between the Ag-As, Ag-Sb, and Ag-Bi systems follows. The article is accompanied by 5 tables and 2 diagrams. OWE (5b)

An X-Ray Investigation of the Tin-Antimony Alloys. E. G. Bowen & W. Morris Jones. *London, Edinburgh, Dublin Philosophical Magazine & Journal of Science*, Series 7, Vol. 12, Aug. 1931, pages 441-462.

A study of the crystal structure was made by the X-ray powder method. The results confirm the existence of the solid solutions and the Sn and Sb ends of the equilibrium diagram. There is an expansion of the Sn lattice and a contraction of the Sb lattice, showing that the atomic radii of these elements are different. The compound SnSb is found to have a sodium chloride structure which persists alone over the entire range from 40 to 54% of Sb with some change of lattice constant showing that there is slight solution of Sb in SnSb and a greater solution of Sn in SnSb. The individual phases of the equilibrium diagram are discussed. 16 references. Ha (5b)

Diffraction Patterns Explain Metal Crystal Structures. R. L. Davidson. *Steel*, Vol. 88, Mar. 26, 1931, pages 48-50.

The principles of making X-ray diffraction patterns and the manner of determining the structure from the photographs is described in an elementary manner. Ha (5b)

On the Accuracy of Interference Measurements in the Molecule with X-rays and Cathode Rays. (Ueber die Genauigkeit von Interferenz-Messungen in der Molekul mit Röntgen- und Kathodenstrahlen.) L. Bewilogua. *Physikalische Zeitschrift*, Vol. 32, Jan. 15, 1931, pages 114-117.

The question "do the wave lengths of cathode rays yield a larger dissolving power due to their being 10-30 times smaller than the X-ray wave lengths" is critically discussed and its limitations are revealed. Then the following question is brought up: "what kind of rays yield the most favorable course of intensities," that is to say a curve with pronounced maxima and minima? The advantages of cathode rays for determining inter-molecular spacings are pointed out and the necessity of applying X-rays in certain cases of complicated molecular space lattice measurements are discussed. The principles of X-ray testing are discussed, practical arrangements are described and the advantages of non-destructive testing are demonstrated. HCD (5b)

A Comparison of the Crystal Structures of Cu_5Zn_8 and Cu_5Cd_8. A. J. Bradley. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Series 7, Vol. 12, July 1931, page 143.

The structures of the 2 bodies are both of the γ type, with 52 atoms in the unit cell; these atoms fall into 4 groups of structurally equivalent positions, containing, respectively, 8, 8, 12, 24 atoms. In Cu_5Zn_8, the atoms cannot be distinguished by X-rays; the interatomic distances are closely the same. In Cu_5Cd_8, the scattering power of the atom is different which makes it possible to check positions and parameters better by the interatomic distances. The distances Cu-Cu are smaller than the distances Cd-Cd; the distances Cu-Cd are intermediate. 11 references. Ha (5b)

Relation of Crystal Orientation to Bending Qualities of a Rolled Zinc Alloy. Gerald Edmunds & M. L. Fuller (New Jersey Zinc Co.). *American Institute of Mining & Metallurgical Engineers, Preprint*, 1931, 11 pages.

A study of crystal orientation in low-alloy Zn sheet indicated that the crystals on the surface were orientated with the hexagonal axis perpendicular to the surface of the sheet. When the orientation peculiar to the surface layer extended to a depth of more than 0.0005 in., poor bending qualities were found. These poor bending qualities were attributed to the unfavorable orientation of possible planes of slip in the surface layer. Orientations are described by the "flächenpolifigur" of Wever. Contains 12 references. JLG (5b)

The Electronic Energy Levels of the Elements, with Special Reference to their Connection with the Sizes and Electronic States of Atoms in Metallic Crystals. Wm. Hume-Rothery. *London, Edinburgh & Dublin, Philosophical Magazine & Journal of Science*, Series 7, Vol. 11, Mar. 1931, pages 649-678.

It has been found that within an accuracy of about 1% simple relations exist between the interatomic distances in the crystals of elements and the atomic numbers and electronic quantum numbers of the atoms concerned. If Z is the atomic number, the interatomic distances vary as $1/Z$, $1/Z^2$, $1/Z^3$, and $1/Z^5$ for the elements at the beginning of the first to fourth periods. The electronic levels vary linearly with Z^2, Z^4, Z^6, and Z^{10} for electrons of the outermost group of electrons of the atomic core or ion. 7 references. Ha (5b)

Practical Applications of X-Ray Diffraction Methods in the Study of Quench and Temper Structures of Carbon Steels. N. P. Goss *Transactions American Society for Steel Treating*, Vol. 19, No. 2, 1931, pages 182-192.

The author describes a study of the X-ray structures of quenched and tempered carbon tool steels. He cites the variables affecting the structure such as chemical composition, thickness and shape of the piece, quenching temperature and medium. X-rays may be used by the metallurgist to determine if a given piece has been properly quenched even after it has been tempered, and to determine the proper quenching conditions for a given job. WLC (5b)

On the Nature of the Eutectoid-Transformation of Aluminum Bronze, Part III, X-Ray Analysis, Part IV, X-Ray Analysis at High Temperatures. (In English). I. Obinata. *Memoirs of the Ryojun College of Engineering*, Vol. 3, No. 4-B, 1931, pages 285-298.

Arguing from the assumption (made by various Japanese investigators but not generally held: abstractor) that austenite always decomposes by passing through martensite, eutectoid transformation in aluminum bronze should also be a "stepped one, by the route $\alpha + \delta \rightleftarrows \beta' \rightleftarrows \beta$. An alloy with 16% Al quenched from 830° C. did not show the γ phase alleged by Stockdale to exist above 780° C., but this cannot be taken as conclusive because the change may not be suppressed by quenching. An alloy with 12.5% Al was found to contain $\alpha + \delta$ and it was decided that it would be necessary to take powder photograms at high temperature or add a third element to retard the velocity of transformation. It was assumed that Mn would exert this retarding effect, so alloys of 12.2 to 12.3% Al with 0, 1, 2½, and 5% Mn quenched in water from 850° C. The results are interpreted as indicating that without Mn, the quenched alloy consists chiefly of hexagonal β' with small amounts of β, while by adding Mn the decomposition of β to β' is retarded. On reheating the quenched alloy and again quenching it was concluded that in the Mn-free 12.5% Al alloy the change $\beta \rightarrow \beta'$ occurs between 400° and 450° C. and $\beta' \rightarrow \alpha + \delta$ at about 500° C. An alloy of 12.4% Al was subjected to X-ray analysis at a temperature not measured but estimated to be about 650° C. and was found to consist solely of β, with a body-centered cubic "super lattice," and a parameter of about 5.89 A. U. HWG (5b)

An X-Ray Investigation of the Lead-Bismuth and Tin-Bismuth Alloys. D. Solomon & W. Morris Jones. *Philosophical Magazine and Journal of Science*, Series 7, Vol. 11, May 1931, pages 1090-1103.

The method of investigation is described; the crystal structures of Pb-Bi and Sn-Bi systems are found to be different from those of the Pb-Sb and Sn-Sb systems although the crystal structures of Sb and Bi are alike. Whereas Pb easily takes Bi into solid solution, Sb is practically insoluble in Pb. Pb, however, is practically insoluble in Bi and Sb. In the Sn-Sb system a compound Sn-Sb exists having a sodium chloride structure, and solid solutions exist both at the Sn end and the Sb end of the equilibrium diagram. Contrary to it, Sn and Bi are just mixtures of the crystalline phases of the elements. 12 references. Ha (5b)

Röntgenographic Examination of Dental Gold Alloys. John S. Shell & Donald McCormack. *Journal American Dental Association*, Vol. 18, Aug. 1931, pages 2193-2194.

Discusses the desirability of this method of non-destructive testing and reports the results of tests on a cast specimen 0.02 in. thick, 0.25 in. wide, and 3 in. long and on a cast "saddle" with 4 clasps. A casting 0.04 in. thick was also examined. The results were reported as encouraging for this type of testing. OEH (5b)

Atom Arrangement and Properties in $Au\text{-}Cu_3$ (Atomordnung und Eigenschaften, Untersuchungen an der Legierung $Au\text{-}Cu_3$). G. Sachs & J. Weerts. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 17, 1931, pages 45-48; *Zeitschrift für Physik*, Vol. 67, Feb. 6, 1931, pages 507-515. 6 figures, 14 references.

The Au-Cu solid solution corresponding to the composition $Au\text{-}Cu_3$ has irregularly distributed atoms at high temperature, but on slow cooling, the atoms take up a more regular lattice position without reaching a regular face-centered lattice arrangement. The behavior may be analogous to the β' to β brass and the α to β iron changes. An alloy of 50.9% Au was studied by X-ray methods. Quenched from 800° C., the lattice spacing was 3.755 A.U.; after annealing at 345° C. for 10 days, 3.751. The electrical resistivity, the elastic modulus, the ductility and the crystal orientation on stretching, were studied. The results are interpreted to indicate that the change of structure is in the direction of producing properties analogous to those of a pure metal. HWG (5b)

Studies on Magnesium and Magnesium Alloys. (Studien an Magnesium und Magnesiumlegierungen.) E. Schiebold & G. Siebel. *Zeitschrift für Physik*, Vol. 69, May 28, 1931, pages 458-482.

See *Metals & Alloys*, Vol. 3, Feb. 1932, page MA 36. JGT (5b)

X-Ray Examination of Electroplated Chromium Coatings. W. A. Wood. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Series 7, Vol. 12, Oct. 1931, pages 853-864.

The conditions of obtaining a certain kind of deposit and the metallurgical characteristics of these conditions are investigated and formulas are developed for the calculation of the grain size and its variation with current and temperature. The existence of a hexagonal chromium, beside the normal body-centered cubic form of chromium, obtainable by electro-deposition, is confirmed. Electrolytically deposited chromium gives very broad X-ray diffraction lines; this is attributed to the very finely divided nature of the deposit. Ha (5b)

Guaranteed by X-ray Inspection. W. H. Shipman (Babcock & Wilcox Co.). *American Machinist*, Vol. 75, Nov. 5, 1931, pages 708-709.

The Barberton plant of the Babcock & Wilcox Co. inspects all longitudinal and girth seams of all pressure vessels. Costs are not prohibitive. Defects revealed include: (1) poor penetration or improper fusion at the scarfs between the weld and the parent metal; (2) laps that are not fused; (3) gas pockets; (4) shrinkage cracks. The Coolidge tube is used with the X-ray apparatus. RHP (5b)

The Relation Between Uranium and Radium. Part 9. The Period of Ionium. Frederick Soddy. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science*, Series 7, Vol. 12, Nov. 1931, pages 939-945.

Earlier parts are identified in the article. The one preceding this, Part 8, appeared in the *Philosophical Magazine*, Series 6, Vol. 47, 1924, pages 1148-1158. Highly theoretical discussion of experimental work on the determination of the period of ionium. Values are lower than those obtained by Stefan Meyer and Mmes. Curie and Cotelle. RHP (5b)

Hyperfine Structure of Mercury. Kiyoshi Murakawa. *Scientific Papers Institute of Physical & Chemical Research* No. 326-327, Vol. 16, Sept. 1931, pages 243-255.

A new description of the hyperfine structure and the Paschen-Back effect of the Hg-line λ = 4046.56 (6^3Po — 7^3Si) is given. The Paschen-Back effect determines uniquely the nuclear moment of all the Hg isotopes: I = 0 for even isotopes; I = ½ for Hg_{199}; I = 3/2 for Hg_{201}. The relative shift of even isotopes in the terms 6^1S_0, 7^3S_1, 7^1S_0 is given. Ha (5b)

Growth of Metallic Crystals in Metal Vapor (Das Wachstum von Metallkristallen in Metalldampf). M. Straumanis (University of Riga). *Zeitschrift für physikalische Chemie*, Sect. B, Vol. 13, Aug. 1931 pages 316-337.

The condensation of Zn and Cd vapor on glass walls in vacuo also takes place if the temperature of the walls is higher than the melting point of the metals if a sufficiently great density of the beam is secured over a certain length of time. Nuclei having been formed, those grow most rapidly to large crystals which are at a temperature slightly higher than the melting point of the metal evaporated. Under a certain limit of temperature (Zn: 375° C.), the crystal growth is strongly checked and the metal is precipitated in fine crystalline powder. A nucleus continues to grow along the diagonal axis of second order, so that the formation of large hexagonal crystal plates limited by parallel base faces takes place. The separation of new lattice planes always starts from the center of the base face. The horizontal growth is stopped after some atom-distances from the edge of the plane beneath; this occurrence is in agreement with the theory of homopolar growth of crystal. Consequently crystals develop into pyramids of the I Order with a truncated face. The boundry faces met with on Cd are (0001), $(20\bar{2}5)$, $(10\bar{1}2)$ and $(20\bar{2}3)$ and in the case of Zn: (0001), $(10\bar{1}1)$, $(20\bar{2}3)$ and $(40\bar{4}1)$. Prism planes are very seldom encountered in either of the metals investigated. The pyramids are built up in the form of terraces and the thickness of the individual plates amounts to 0.8 ± 0.1 μ or a multiple number thereof in the case of Cd. The evaporation proved to take place in an arranged manner too, and disclosed the reversed order of the condensation process outlined above. The investigators set forth interpretations of their observations on the crystal growth of Zn and Cd on the basis of the theory of Kossel and Stranski. EF (5b)

Registration of Cathode Rays by Thin Films of Metals and Metal Compounds. Warren W. Nicholas & C. G. Malmberg. *Bureau of Standards Journal of Research*, Vol. 8, Jan. 1932, pages 61-65.

A search was made for a method of registering cathode rays analogous to the photographic method which could be carried out entirely in daylight and in which no development process would be required. For this purpose thin metal films (Pb, Ag, Bi, Sn, Cd, As, Cu, Sb, Zn, Mg, Se) were deposited on glass by evaporation from a coiled tungsten filament in vacuum. These were then exposed, in vacuum, to a beam of 10 kv cathode rays. Films of Pb and Sn so thin as to be quite transparent before exposure, were darkened to a density of the order of 0.5 by exposure to 0.01 coulomb/cm.² Also opaque films of the above metals were exposed to the vapors of various acids (HCl, HNO_3, HBr, HI, H_2S, H_2SO_4); this generally produced a lowered opacity, in many cases the films becoming transparent. Exposure to cathode rays tended to restore the original opacity. In general, the best effects were obtained with nitrates and bromides; $Bi(NO_3)_3$ seemed to show the most promise as to sensitivity and permanence of the record. The cathode ray bombardment caused practically all the films to fluoresce, the color and intensity of the fluorescence depending on the material. WAT (5b)

X-Ray Investigation on the Hydrides of Titanium, Zirconium, Vanadium and Tantalum (Röntgenuntersuchung über die Hydride von Titan, Zirkon, Vanadin und Tantal). G. Hägg (University of Stockholm). *Zeitschrift für physikalische Chemie*, Sect. B, Vol. XI, Feb. 1931, pages 433-454.

Several hydride phases of Ti, Zr and Ta were found, all showing a rather simple atomic arrangement. Due to inhomogeneities, experiments with V did not yield useful photograms worthy of interpretation. The radius of the hydrogen atom gave an average value of 0.46 A.U. The ranges of homogeneity of the Ti-H, Zr-H and Ta-H systems are schematically presented. EF (5b)

Supplementary Remark to the Paper "Crystallographic Structure of Fe_2B". (Berichtigung zu der Arbeit "Kristallbau der Verbindung Fe_2B"). G. Hägg (University of Stockholm). *Zeitschrift für physikalische Chemie*, Sect. B, Vol. 12, June 1931, pages 413-414.

The structural arrangement of Fe_2B becomes a higher symmetry as previously stated (*Zeitschrift für physikalische Chemie*, Sect. B, Vol. 11, No. 2/3, pages 152-162) if the vertical parameter of the Fe-atom amounts to exactly 1/4. The analogy between the Fe_2B structure and the $CuAl_2$ structure is pointed out. EF (5b)

Interferometric Measurements in the Arc Spectrum of Iron. C. V. Jackson. *Proceedings Royal Society*, Vol. A130, 1931, pages 395-410.

Interferometric measurements were made of 10 lines in the Fe arc spectrum between 4000 and 4400 A.U. by comparison with the red Cd line and the secondary Ne standards. Measurements have also been made of 68 lines between 2300 and 3100 A.U. in the Fe arc and 5 lines in Hg from 2652 to 3125 A.U. The results are in good agreement with other investigators and with calculated results obtained from energy levels. WAT (5b)

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Brinell Ball Hardness Tests. MICHITOSHI ICHIHARA. *Technical Reports Tohoku Imperial University,* Vol. 10, No. 1, 1931, pages 25-41.

Cross-sectional curves of the indentation made by a Brinell ball were measured by means of an optical lever arrangement for such materials as low C steel, mild steel, Cu, cast Fe, Sn, Zn, bronze and Al. An empirical formula is given for these curves, which is claimed to be applicable to all the metals mentioned with an error of less than 2/1000 mm. (6)

New Studies on the Nature of Abrasion. Correspondence from S. SAITO, Osaka, Japan. *Metal Progress,* Vol. 21, Feb. 1932, pages 70 and 90.

The writer describes certain abrasion tests and his explanation of the mechanism of abrasion is presented. WLC (6)

Cracking of Reinforcing Bars at Cold Bends. TH. WYSS (Federal Testing Laboratory, Zurich, Switzerland). *Civil Engineering,* Vol. 1, Nov. 1931, pages 1266-1268.

At the first International Congress on Concrete and Reinforced Concrete, held in September 1930, at Liege, Belgium, the author presented a brief paper giving a simple but effective explanation of an embrittling phenomenon which occurs under certain conditions in ductile steel, in particular at the concave side of cold bends made in reinforcing bars. The steel on the inside of the bend undergoes plastic deformation in compression, which may be so great that when the bending forces are relieved the residual internal tensile stresses developed by the cold bending may result in the formation of a crack on the inside of the bend. It was shown that after ductile steel has been plastically deformed in compression 20% or more it becomes extremely brittle when subsequently subjected to tensile loads. This embrittling phenomenon may explain some of the perplexing cases of failure where a very ductile steel part has broken in service as if the material in it were devoid of all ductility and under conditions where the break cannot be attributed to the fatigue of the metal. WAT (6)

Shear Tests for Cast Iron. H. H. JUDSON. *Proceedings American Society for Testing Materials,* Vol. 31, Pt. 2, 1931, pages 304-316.

Includes discussion. Shear specimens cut from actual castings, a boss being cast solid and the specimen trepanned from it, show correlation of single shear strength and bursting strength of the pump cylinder castings from which they were cut. At 1000 lbs. bursting strength the shear strength was 15,000 lbs./in.^{2}, rising almost linearly to 43,000 lbs./in.^{2} at 4000 lbs. bursting strength, then the curve breaks, but is again almost linear to 55,000 lbs./in.^{2} at 6500 lbs. bursting strength. The shear strength is from 1.10 to 1.15 times the tensile strength, both determined on parts of actual castings. The practical control afforded by tests of the casting itself through small trepanned shear specimens is better than with separately cast test bars. In discussion, J. Shaw pointed out that poor material may pass the shear test that would not pass other tests. Bornstein and MacKenzie thought that a test bar designed to have the same cooling rate as the casting would be preferable. Capp approved the idea of determining the properties of the casting itself. MacPherran thought the test might be useful. HWG (6)

A Comparative Study of Some Properties of Pig-Irons. J. E. HURST. *Foundry Trade Journal,* Vol. 45, Nov. 26, 1931, pages 337-339.

A paper accompanied by 4 tables and 3 diagrams, showing the stress deflection curves for 3 different classes of iron. It discusses the ultimate breaking strength, the stress deflection curves, and the modulus of elasticity, pointing out that the ultimate breaking strength alone is insufficient as a measure of the toughness of cast iron, whereas the area included by the stress-strain curve is a very close measure of this property. This, however, is insufficient, and attention needs to be directed to the character of the deformation sustained during load and to the shape of the curve. The transverse test, as ordinarily carried out, including the measurement of total deflection, is only a partial guide to toughness in view of the fact that it gives no record whatever of such phenomena as have been described above. OWE (6)

Using Elongation Measurements in Practice. (Der Nutzen von Dehnungsmessungen in der Praxis.) JOSEPH GEIGER. *Maschinenbau,* Vol. 10, Dec. 3, 1931, pages 709-710.

Discusses the impossibility of calculating strains which develop in objects, and how they are supposedly measured, considering specifically the observed values in stationary elongation tests. The results, if accurate, are of prime importance in machine parts (such as piston rods, driving rods, and crankshafts). Describes dynamic elongation tests. MAB (6)

Supplementary Methods of Stress Analysis. HERBERT J. GILKEY & ELMER O. BERGMAN. *Civil Engineering,* Vol. 2, Feb. 1932, pages 97-101.

Mathematical solutions of the stresses in simple engineering structures can be made with reasonable exactness, but a full theoretical analysis of the complex stresses in intricate structures is only possible in a few special cases. Experimental methods must be resorted to, such as the use of strain gages, the testing of models made of various materials, the method of analogy, the study of yield lines on the surface of members stressed to the elastic limit, or the examination of photo-elastic images produced by passing polarized light through stressed models. Good judgment is required in choosing the proper experimental method for verifying or checking the mathematical analysis used. These various experimental methods for attacking complicated problems of stress distribution are discussed. The testing of steel beams to be used in the Delaware River Bridge and the formation of stress lines thereon is described and illustrated. A number of reproductions of images of photo-elastic examinations of beams under various conditions of loading are also presented. The use of models in the study of stresses in large dams such as the Stevenson Creek, Gibson, and Hoover is also dealt with. A selected bibliography is given. WAT (6)

The Unbalanced Alternating Current Bridge for Magnetic Analysis II. W. B. Kouwenhoven & J. H. Lampe. *Proceedings American Society for Testing Materials,* Vol. 31, Pt. 2, 1931, pages 107-128.

Includes discussion. See abstract of preprint, *Metals & Alloys,* Vol. 2, Nov. 1931, page 255. HWG (6)

Report on Wear Tests on the Amsler-Machine. Influence of the Reciprocal Motion of the Test Roll (Bericht über Verschleissprüfungen auf der Amsler-Maschine. Einfluss der Hin- und Herbewegung der Versuchsrolle). Mehovar. *Zwanglose Mitteilungen der deutschen und oesterreichischen Verband für Materialprüfungen der Technik,* No. 19, Sept. 1930, pages 262-263.

If the test roll was given an axial movement of 2-3 mm., the normal wear was increased 2-3 times and the dispersion from ±0.6% to about ±20%. Ha (6)

A Simple Method of Studying the Stress-Strain Relation in the Notched-Bar Impact Test. Tadashi Kawai. *Science Reports, Tohoku Imperial University,* Series I, Vol. 19, 1931, pages 727-743.

By the ordinary method of applying the notched-bar impact test, the value of the impact energy required which is just sufficient to break the test piece, is found, but not the stress-strain relation. Though the impact value is a measure of the toughness of metals, it does not give any information as to the behavior of the metals under load, as is obtained by the statistical test. Hence, the present writer has devised a simple method for determining the energy-strain and stress-strain relation in notched-bar impact test, by using an ordinary Charpy machine. (6)

The Determination of the Static Bending Stresses in Laminated Springs (Ueber die Ermittlung der statischen Biegespannungen in geschichteten Federn). *Automobiltechnische Zeitschrift,* Vol. 34, Nov. 30, 1931, pages 751-756.

The object of this investigation is to determine from the measured deformation of the layers of the spring the forces occurring between the individual leaves which are themselves unknown and to calculate from this the actual bending stresses in the individual laminae of the spring. This calculation is carried out for the laminated spring, loaded and not loaded. A formula is developed for the calculation of the forces which are transmitted at the ends of a leaf to the next one on top of it. The method of calculation is illustrated by an example. Ha (6)

Measurement of Stresses in Billets Quenched on one Side. (Spannungsmessungen an einseitig abgeschreckten Knüppeln.) F. Stäblein. *Stahl und Eisen,* Vol. 52, Jan. 7, 1932, pages 15-17.

The paper corresponds to the publication in *Krupp'sche Monatshefte,* Vol. 12, May 1931, pages 93-99 as abstracted in *Metals & Alloys,* Vol. 2, Nov. 1931, page 255. GN+DTR (6)

Six Methods now in Use for Non-destructive Weld Tests. *Steel,* Vol. 89, Dec. 14, 1931, pages 34-35.

A brief discussion of the principle of these methods; hydrostatic pressure test, air pressure test, low pressure test, reheating test, stethoscope test, and X-ray test. Ha (6)

Fatigue of Metals & Alloys (6f)

Unequal Loading Decreases Elevator Rope Life. A. S. Rarden (American Cable Co.). *Power,* Vol. 74, Nov. 10, 1931, pages 683-684.

The fatigue life of the outer wires of the strands next to the core is proportionately increased as compared to the fatigue life of the outer wires on the outer strand crowns with increased loads on the rope. AHE (6f)

Corrosion-Fatigue Tests of Mild Steel and Chromium-Nickel Austenitic Steel in River Tees Water. N. P. Inglis & C. F. Lake. *Transactions Faraday Society,* Vol. 27, Dec. 1931, pages 803-808.

The following gives results obtained in rotating beam type fatigue testing machines with River Tees water dripping on the specimen. Analysis of water is, per 100,000 parts, total solids 2954, lime 48, magnesia 164, SO_3 176, $Fe_2O_3 + Al_2O_3$ 0.4, chlorine as Cl 1441.0.

Material	Fatigue Limit in air tons/in.²	Corrosion Fatigue Limit in River Tees Water tons/in.²
Mild Steel (0.2% C) normalized from 900° C.	±17.0	Nil.
18/8/1 (17-19 Cr, 8-10 Ni, 0.6-1.0 W, C < 0.16) ¾" bar heated to 1100°-1150° C. and water quenched	±17.6	±11.1
The same steel but drawn at 650° C. for 8 hrs. and air cooled	probably same	±6.5

The fracture was shown to be predominantly transcrystalline in corrosion fatigue failures. It is suggested that the effect of repetitions of stress is to cause a continual breaking down of surface passive film, favoring pit formation which may take the form of minute intercrystalline fissures. When the resultant intensification of stress is greater than fatigue limit failure proceeds by ordinary fatigue. PRK (6f)

A Few Remarks on the Choice of Residual Loading of Material. (Einige Bermerkungen über die Wahl der zulässigen Anstrengung der Werkstoffe.) Otto Graf. *Maschinenbau,* Vol. 10, Feb. 5, 1931, pages 84-85.

The paper discusses recent tests on the endurance strength of steels, particularly of rolls and borings. MAB (6f)

Endurance Properties of Some Well-Known Steels in Steam. T. S. Fuller. *American Society for Steel Treating, Transactions,* Vol. 19, No. 2, 1931, pages 97-114.

Endurance Testing of Steel: Comparison of Results Obtained with Rotating Beam versus Axially Loaded Specimens. R. D. France. *Proceedings American Society for Testing Materials,* Vol. 31, Pt. 2, 1931, pages 176-193.

After a complete overhauling of 2 Haigh tension-compression fatigue machines so as to fit them for precise work and insure axial loading, 14 ferrous materials were compared at the Bureau of Standards in axial loading and in rotary beam (R. R. Moore machine) tests. The specimens were aligned with the most scrupulous care to insure axial loading. Materials tested were open hearth iron, wrought iron and steels of 0.45 to 0.87% C including rail steels. Rotating beam results were always higher than those by axial loading. Annealed steels showed a much lower ratio of axial to rotary beam endurance limit than they did after oil quenching and tempering at 1000° F. or over. The ratios for the materials tested varied from 74% to over 99%. The more homogeneous the material the higher the ratio. Includes discussion. HWG (6f)

The Influence of Holes on the Endurance Limit of Steel Specimens (Der Einfluss von Bohrungen auf die Dauerfestigkeit von Stahlstäben). G. Barner. VDI-Verlag, Berlin, 1931. Paper, 6 x 8¼ inches, 50 pages. Price 5.50 RM.

The effect of notches upon stress-concentration is first discussed and data tabulated from the literature to show the effect of various types of notches on the endurance limits of various alloys. Rotating beam endurance tests were carried to 10 million cycles and axial loading tests (on an Amsler tensile machine with pulsator) to 2 million cycles. The rotating beam specimen was 7.52 mm. in diameter, tested (a) polished, (b) with a 0.7 mm. hole bored normal to the axis, (c) with a 60° V notch 0.2 mm. deep cut all around the specimen. The Amsler specimens were 10 to 22 mm. wide, 15 to 18 mm. thick, tested either without a hole or with a 1 mm. hole bored in the middle of the test length. The Amsler specimens were made 4 in series of widths of 10, 14, 17 and 22 mm. so that when the smallest one broke, the next could be regripped and the test continued. 3 steels were tested. (a) Hard structural steel (micrograph shows high carbon) 85,000 lbs./in.² tensile 53,500 yield, 22½% elongation, 52% reduction. (b) Soft structure steel 58,500 tensile, 35,500 yield, 29% elongation, 63% reduction. (c) Alloy structural steel (composition not given) 74,000 tensile, 47,000 yield, 27% elongation, 60% reduction. In rotary bending, (a) gave, polished, 45,000 lbs./in.²; bored (hole smoothly finished) 24,000 lbs./in.²; notched 31,000 lbs./in.² endurance limit. On the Amsler test between minimum and maximum tension stresses such that the maximum was 4 times the minimum, steel (a) gave 59,000 lbs./in.² machined; 55,000 lbs./in.² with rolling skin; 42,500 lbs./in.² with smooth hole; 35,500 lbs./in.² with rough hole. Steel (b) gave, with rolling skin 42,500 lbs./in.²; with rough hole 32,500 lbs./in.². Steel (c) gave with rolling skin 39,000 lbs./in.²; with rough hole 30,000 lbs./in.². The rolling skin on (c) has microscopic cracks.

ELECTRO-CHEMISTRY (7)

The Electrolytic Solution Tension and the Necessity of Taking into Account the Galvanic Potential Metal/Metal in the Galvanic Chain. (Ueber die elektrolytische Lösungstension und die notwendige Mitberücksichtigung des Galvanipotentials Metall/Metall in der Galvanischen Kette.) H. Hammerschmidt & E. Lange. *Physikalische Zeitschrift,* Vol. 32, Dec. 1, 1931, pages 958-964.

The problem of the electrolytic solution tension is complicated due to the phenomenon of a galvanic potential between 2 metals, which has not always been properly accounted for. A partial analogy between the ordinary 2 phase system (electro-neutral solid phase—saturated solution) and the electro-chemical binary system is pointed out with reference to the ideal zero concentration and the ideal solution tension which represents a normal measure for the energy occurring during the transition of an ion from the solid phase into the attraction forces of a solution. The concentration due to the dipole participation on the building up of the electrolytic double layer does not coincide with the ion absorption deciding the potential. In the second place this concentration does not coincide with the zero point of the accompanying volta potential due to the occurrence of the surface potential of the pure faces. Neither zero point offers a possibility of determining the ideal zero point concentrations of the solution tensions. In addition to that 2 ideal zero electrodes combined in a galvanic chain would not yield any clues in regard to the e.m.f. The data found in literature on the true zero point concentration and on the true solution tension neither furnish any information on the absolute and relative value of the galvanic potential of a single electrode nor on the normal ion transition energy, but only give the e.m.f. of certain galvanic cells. The author recommends paying regard to the galvanic potential metal/metal in order to exclude false conclusions in electrochemistry.

Electroplating (7a)

Nickel and Chromium Plating at High Current Density. *Brass World,* Vol. 27, Sept. 1931, pages 199-200.

The greatest problem of Cr plating has been the securing of satisfactory adhesion of the Ni undercoat. Problems peculiar to high current density may be grouped as follows: (1) the inclusion of foreign matter in the deposit, due to necessary vigorous agitation; (2) the difficulty of securing adequate deposits on recessed surfaces owing to low throwing power; (3) variations in thickness of deposits due to contact resistance, excessive current density at the bottom of the articles and to screening effects. The Ni plating, Ni mopping, and Cr plating are discussed. High current density Cr plating solutions have maximum throwing powers.
WHB (7a)

Chrome-Plating of Brass and Alpaca. (Das Verchromen von Messing und Alpaka.) Karl Schuch. *Oberflächentechnik,* Vol. 8, Dec. 15, 1931, pages 255-256.

The best practice for chrome plating of brass is now considered to be using an intermediate layer of Ni which should contain as little hydrogen as possible and should be soft; the Cr layer need then be only very thin and serves as hardener. The following Ni bath is recommended: 100 L. water, 10 kg. nickel sulphate, 1.5 kg. sodium citrate, 1 kg. sodium sulphate, 0.8-1.0 kg. boric acid, 0.25 g. citric acid; the gravity is 10-12° Bé., the bath temperature 35 to 40° C., the acidity should be between 5.2 and 5.9 pH; the voltage is 3-3.25 volts, and the current density 0.8-1.0 amp./dm.^{2} Alpaca is greatly used in the cutlery industry. Chrome-plating is here recommended instead of silver plating as the former does not tarnish as easily as silver. The pieces must be well polished before chrome-plating. Detailed information is given for the treatment, degreasing and subsequent cleaning.
Ha (7a)

The Analysis of Cyanide Silver-Plating Solutions. R. M. Wick. *Bureau of Standards Journal of Research,* Vol. 7, Nov. 1931, pages 913-933.

Methods for the analysis of cyanide silver-plating solutions were studied, including the determination of free cyanide, total cyanide, carbonate, chloride, ammonia, Ag, Fe, Cu and Hg. Electrometric titrations showed that the Liebig method for alkali cyanide is correct to better than 0.2%. Addition of KI make the method still more accurate and overcomes the effects of impurities on the titration. The non-agreement of the Liebig and Hannay methods was studied by electrometric titrations, which showed that the visual Hannay method gives high results although the electrometric Hannay titration is accurate. The determination of the total cyanide was accomplished by distillation with sulphuric acid and of total effective cyanide by titration with I. Ag may be separated as silver sulphide, by precipitation with Zn, or by decomposition with acid, after which a determination by any standard method is applicable. Carbonate may be determined by precipitating and filtering out barium carbonate and titrating it with acid or by titrating a sample with acid after adding silver nitrate to combine with the free cyanide. The usual method for the determination of chloride involves prolonged treatment with nitric acid, which converts the precipitated silver cyanide to silver chloride. A new method for separating chloride was investigated in which the Ag was precipitated as sulphide and the iron is removed by precipitation as manganous ferrocyanide. The chloride in the filtrate can be determined by the usual methods. Fe and Cu can be determined by the usual analytical methods after decomposition of the plating solution with sulphuric acid. Hg can be determined by precipitation as sulphide along with silver sulphide. The mercuric sulphide is extracted from the mixed sulphide precipitate with sodium hydroxide, reprecipitated and weighed. A new method was developed for the determination of ammonia in cyanide solutions, in which the free cyanide is converted to the Ag complex preparatory to the usual distillation. Direct distillation is not satisfactory because ammonia is formed by decomposition of alkali cyanide at elevated temperatures.

Electrometallurgy (7b)

The Electrolytic Refining of Tin at the Mitsubishi Osaka Refinery. Z. Kimura. *Journal Mining Institute of Japan,* Vol. 47, No. 558, 1931, pages 966-1001.

The electrolytic refining of the crude tin obtained in the reverberatory furnace of the Ikuno Mine dates from 1916. Since the plant was removed to the Mitsubishi Osaka Refinery in 1920, the author has developed it into the present one which produces more than 80 tons/mo. Systematic studies to find the best composition of the electrolyte are described in this report. The chief factors studied were the dissolution of the anode, the state of the anode slime, the effects of hydrolysis and the purity of the cathodic deposit. The composition of the crude tin from the Ikuno mine is as follows: 90-96% Sn, 2-5% Cu, 0.3-0.7% Pb, 0.3-0.6% Bi, 0.07-0.21% Fe, 0.4-0.6% As, 0.5-0.6% Sb. The elimination of Cu was considered principally in this case. The plain sulphuric acid bath is inapplicable owing to the hydrolysis of Sn, and the addition of NaF, HCl, some sulphates and cresol sulphonic acid did not bring satisfactory results. Although the hydrofluosilicic acid bath which has long been used in the plant is excellent, its cost is rather high and the author tried to replace some portion of the acid with H_2SO_4. The rate of diminution of the stannous ion concentration during electrolysis was more affected by increase in temperature than by that in the H_2SO_4 concentration. The electrolyte containing 5.6% H_2SiF_6 and 6% H_2SO_4 may satisfactorily be applied to the anode with the purity of 95.4% at 18° C. and even to the 90% one if the current be reduced to 0.4 A/dm.^{2} As the presence of H_2SiF_6 has been found to be necessary only for preventing the hydrolysis of tin salts, its concentration is now being progressively reduced in practice. The cresol sulphonic acid bath with the strength of 16% (including the uncombined H_2SO_4) was good above 30° C. but its weak points are the high cost and the low current density required. Although the concentration of the acid can be reduced by adding some H_2SiF_6, much value can not be set upon it as the simple H_2SiF_6 and H_2SO_4 mixture was sufficient.
YO (7b)

Examples of Hydrometallurgical and Electrometallurgical Operations. III. Refining of Gold and Silver. Thomas P. Campbell. *Colorado School of Mines Magazine,* Vol. 21, No. 8, Aug. 1931, pages 11-16.

In acid parting, hot concentrated H_2SO_4 is replacing HNO_3. Acid parting operations may be outlined as: (1) blending of the bullion and preparation for parting; (2) dissolution of Ag and base metals; (3) treatment of the residues for Au; (4) treatment of the solution for Ag. The Moebius and Balbach refining processes for Ag and the Wohlwill process for Au are described.
WHB (7b)

Copper-Electrolysis of the Zinnwerke Wilhelmsburg G. m. b. H. (Die Kupferelektrolyse der Zinnwerke Wilhelmsburg G. m. b. H. zu Hartburg-Wilhelmsburg bei Hamburg.) Georg Eger. *Siemens-Zeitschrift,* Vol. 11, Dec. 1931, pages 537-541.

A general description of the electrolytic refining process is given; the works' equipment and installations for an output of 50 tons per day is described in detail.
Ha (7b)

Manufacture of Aluminum by Electrolysis. *Journal Society Chemical Industry,* Vol. 50, Feb. 6, 1931, page 121.

The bath comprises a mixture of aluminum fluoride and sodium or potassium carbonate in the molecular ratio 4 : 5 instead of cryolite. On fusion, this mixture yields a solution of alumina in cryolite.
(7b)

Electrodeposition of Metals from Anhydrous Ammonia. Harold Simmons Booth & Menahem Merlub-Sobel. *Journal of Physical Chemistry,* Vol. 35, Nov. 1931, pages 3303-3321.

The authors show that many metals can be deposited cathodically from anhydrous ammonia solutions of their salts in compact adherent form. Bi cannot be so deposited. Be, which is not deposited from aqueous electrolytes, can be deposited from ammonia. A description is given of a cell which has been designed for high-pressure electro-deposition studies.
OWE (7b)

INDUSTRIAL USES AND APPLICATIONS (9)

Beryllium Alloys Improve Springs. *Scientific American*, Vol. 146, Jan. 1932, page 58.

The properties of Be have been exploited in the manufacture of springs which retain their elasticity even at a red heat. Ferrous alloys containing 1% Be, 12% Cr and more than 8% Ni are used. Compared with the best W special steels with high creep limit, these Be steels have a temperature advantage of 50°-100° C. WAT (9)

Cupro Nickel Condenser Tubes (Los Tubos De Condensadores En Cuproniquel). *Revista Minera*, No. 3248, Jan. 1932, page 32.

Cu-Ni alloy (70:30) or monel metal gives best results for fabrication of condenser tubes. It is far more resistant than formerly used copper-brass (70:30), with or without Sn. Such tubes cost more than brass tubes but have longer life and higher scrap value. Mechanical properties are superior, which permits decreasing thickness; "season cracking" resisted. Conductibility in c. g. s. units; Cu-Ni, 0.07; monel metal, 0.06; brass, 0.24. DTR (9)

Round Table Discussion on Cast Iron Pipe. *Water Works Engineering*, Vol. 84, July 15, 1931, page 1011.

On the question "Do you favor cast iron pipe made in 12, 16 or 18-foot lengths? Why?" the tabulated replies from water works superintendents were as follows: 14 favored 12-ft. lengths; 17, the 16-ft. lengths; 9, the 18; and one the 24-ft. length. CBJ (9)

Bolts, Screws and Nuts, Materials and Manufacture. Recommended Practice Committee, A. S. S. T. *Metal Progress*, Vol. 20, Nov. 1931, pages 66-68.

Recommended steels, manufacturing operations and heat treatment for these parts are discussed. WLC (9)

Lead Covered Cable. *Wire & Wire Products*, Vol. 6, Oct. 1931, pages 402-404.

A general description of types and uses of lead cables. The properties of the cable sheath metal are discussed; it must be easily pliable and have a tensile strength of at least 4000 lbs./in.^{2}. Pure Pb is usually used for power cables; an alloy with 1% Sb has given good service. Recently, a Pb-Ca alloy with 0.03-0.04% Ca cooled from an extrusion temperature of 225°-250° C. has been developed which is said to be of excellent quality. The lengths of cable, especially of heavy power cables, are made so as to fit the particular use without having to cut it. Ha (9)

Copper Ground Rod Has Steel Core. *Electrical World*, Vol. 98, Oct. 3, 1931, page 628.

The Bridgeport Brass Co. has marketed a Cu ground rod with heavy Cu exterior securely bonded to a rigid steel core. The Cu as applied will not fold, slip, wrinkle nor pull loose during driving and it defies the moisture and corrosive action of the soil. The rods are available in standard sizes. WHB (9)

Recent Developments in Poppet Valves. *S. A. E. Journal*, Vol. 29, Nov. 1931, pages 404-405.

A discussion of A. T. Colwell's paper which appeared in the July *Journal of the S. A. E.* Discussers of this paper submit experiences with various types of valve seat materials which are used in aeronautic and other types of engines. Valves of the motor coach engines are said to operate under harder conditions than those of aircraft engines. Excessive heat is given as a cause of pick-up from the valve seats and even from valve stem guides. A hope is voiced for a steel that is suitable for valves which will have thermal conductivity as good as that of ordinary C steel. WAT (9)

Opportunities in Architecture. *American Machinist*, Vol. 74, Jan. 1, 1931, pages 2-5.

Briefly reviews the history of building. Discusses the use of metal in building, some all metal buildings already built and the probable field for the all metal buildings. Does not consider building methods. RHP (9)

First Stainless Steel, Shot Welded Airplane Tested. *U. S. Air Service*, Vol. 16, Dec. 1931, page 48; *Aero Digest*, Vol. 19, Dec. 1931, page 60.

Test flights were recently completed on an amphibian employing a new type of metal construction. Designed by the American Aeronautical Corp., this new airship is of "shot welded" stainless steel. It was built after several years of research and experiment by the metallurgists and welding technicians of the Edward G. Budd Mfg. Co. in collaboration with the designers, under the direction of Enea Bossi, who acquired the second flying license issued by the Italian government more than 20 years ago. According to the builders, extensive tests have shown that stainless steel has less bulk than duralumin, being from 6-8% lighter than dural, and from 10-14% lighter than wood. WAT (9)

Why—Where—How to Sell Steel Ceilings. *Sheet Metal Worker*, Vol. 22, July 10, 1931, pages 404-406.

Notes the great possibility, especially in existing buildings, of replacing ceilings and walls by steel sheeting. A more pleasing job is often obtained at a saving in price. Ha (9)

The All-Welded Dwelling House. *Sheet Metal Worker*, Vol. 22, Sept. 4, 1931, pages 523-524.

A detailed and illustrated description of a 2 story house 32 x 26 ft., basement and garage. Ha (9)

Electric Line Installs High-Speed Aluminum Cars. *Railway Mechanical Engineer*, Vol. 105, Sept. 1931, pages 437-439, 448.

Describes manufacture of a car of 46 ft. over all length, 50,000 lbs. light weight. Aluminum alloys are used in the construction of frames and body, air brake and other equipment. A saving of 40,000 lbs. was effected in the light weight. Ha (9)

Steel Houses of Germany and France are Mostly Small. Thomas J. Foster (National Bridge Works). *Iron Age*, Vol. 128, Sept. 3, 1931, pages 623-625.

Fifth installment dealing with the use of steel in the building of private homes. Large amounts of Cu bearing steel sheets or light plates have been used. Ingenious methods of construction have been developed in both France and Germany. VSP (9)

Steel Tubes with Cast Alloy Linings. *Power*, Vol. 73, June 23, 1931, page 1008.

Steel tubing lined with a variety of metals or alloys in which the bonding of the 2 metals by fusion is said to be so complete that there is no evidence of separation and no manual means of destroying the union is announced by the Detroit Seamless Steel Tubes Co., Detroit, Mich. Applications are steel-backed bearings, tubes for corrosive liquids and for water-tube boilers where a lining metal of high heat conductivity is advantageous. VVK (9)

The Light Alloys in Decoration (Le leghe leggere nell' arredamento). *Metalli Leggeri*, Vol. 1, May-June 1931, pages 25-33.

Discussion and photographs of applications in architecture, household, furniture, show cases, etc. HWG (9)

Petroleum Industry Increases Applications of Low-Cost, Corrosion-Resisting Cast Iron. *Inco*, Vol. 10, No. 4, 1931, pages 15-16.

The depreciation of pipe lines in the petroleum industry is very high, varying from 5% to 25%/yr. A special alloy "Ni-Resist" is particularly recommended for commercial purposes of this kind. It is available in all forms of castings for the requirements of the petroleum industry. Hardness and corrosion diagrams are reproduced. Its composition is as follows:

	Minimum	Maximum
Total C	2.75	3.10
Si	1.00	2.00
Ni	12.00	15.00
Cu	5.00	7.00
Cr	1.25	4.00
Mn	1.00	1.50
S	0.04	0.12
P	0.04	0.30

Ha (9)

Sheet Metal Products. *Iron & Steel of Canada*, Vol. 14, Mar. 1931, pages 47-49, 58.

An article, accompanied by 11 photographs, in which are described methods of fabricating such things as bedsteads, doors, etc. from oxwelded sheet metal. OWE (9)

All Welded Oil and Gas Field Storage Tanks. Orville Adams. *Welding*, Vol. 2, Nov. 1931, pages 737-741.

Tanks of a capacity from 5000 to 80,000 bbls. are now welded without the use of stitching rivets or fitting-up bolts; mill run steel is used without being resquared. The method of construction, erection and welding is described in detail and results of tests with lap and butt welding with single and double strap are reproduced. The saving in material and shop work is estimated to be as much as 25-30% of the total cost. Ha (9)

Hollow Copper Cables for Electrical Transmission Lines at High Voltage (Les cables creux en cuivre utilisés pour les lignes des transmission d'énergie électrique a haute tension). *Cuivre et Laiton*, Vol. 4, Sept. 30, 1931, pages 423-425.

The increase of the diameter of the cable is the most effective means for the reduction of the corona losses in high-tension transmission lines. Hollow cables, therefore, of the same section as the solid cable would have are used. Beside the reduction of corona losses, the hollow cable can carry a greater current for the same temperature increase:

Section	Cable	Amperes admissible for temperature increase of 10°C.	15°C.	20°C.	25°C.	30°C.
185 mm.^{2}	solid	263	322	372	416	456
	hollow	313	383	442	495	542
210 mm.^{2}	solid	289	354	408	456	500
	hollow	350	428	495	553	606

The construction of such cables and the methods of connection are briefly described. Ha (9)

Production of Sheet Metal Containers. S. D. Brootzkoos. *Metal Stampings*, Vol. 4, Apr. 1931, pages 301-305.

First part of a serial article. Deals with early manufacturing developments and standard specifications for tin cans of various types. MS (9)

Copper-Back Boilers in Kitchen Grates. *Engineer*, Vol. 151, Jan. 16, 1931, page 73.

Extensive tests have recently been made by the city of Birmingham gas department with the coöperation of the Copper and Brass Extended Uses Council. Tests were carried out to determine whether coke could be used as fuel without causing external corrosion of the Cu used in kitchen boilers. Results showed Cu to be very serviceable. Coke did not cause corrosion of the Cu. Specially refined Cu is more stable than either cold or hot rolled Cu. See also comments in *Engineering*, Vol. 131, Feb. 20, 1931, page 269 under the title "Coke Fires and Copper Flue-Back Boilers." LFM (9)

Golden Gate Bridge to be Longer Than Hudson River Bridge. *Iron Age*, Vol. 127, June 18, 1931, pages 1979, 2008.

Suspension structure measuring 4,200 ft. between centers of supporting piers with suspended side spans of 1,125 ft. each, making a total length of 6,450 ft.; each tower to be 746 ft. above water and made of steel. Designed for a dead load of 21,600 lb. for each linear ft. on main span, and 20,300 lb. on side spans. C and Si steels used. Wire specifications call for cold-drawn, with minimum ultimate strength of 220,000 lb./in.^{2} Yield point, 16,000 lb. and cable stress of 82,000 lb. Ductility is 4% elongation in 10 in. VSP (9)

Lead Sheaths for Cables. N. A. Allen. *Electrical Review*, Vol. 108, Feb. 13, 1931, pages 275-276; Feb. 20, 1931, pages 321-322.

The requirements which lead-covered cables must fulfill from the mechanical, chemical and physical points of view and which vary considerably for aerial, underground and submarine cables, are discussed thoroughly. The lead-improving alloys are described and their prices considered. It is demonstrated that, taking into account all relevant factors (as well as costs) the most suitable sheathing for paper insulated cables, both for general purposes and particularly for severe conditions, is lead antimony. Ha (9)

Babbitt Bearing. Robert E. Bultman (White Motor Co.). *Metal Progress*, Vol. 20, Nov. 1931, pages 55-56.

The author discusses the composition, casting conditions, grain size, and virgin raw materials used in the production of White Motor babbitt bearings. WLC (9)

HEAT TREATMENT (10)

Heat Treatment for Aircraft Engine Crankshafts. E. F. LAKE. *Heat Treatment & Forging*, Vol. 17, Aug. 1931, pages 763-767.

Instructions for annealing, hardening and tempering, with micrographs of the structural changes caused by quenching and tempering at different temperatures are given. Ha (10)

The Heat Treatment of the γ-Monohydrate of Ferric Oxide. R. D. WILLIAMS & J. THEWLIS. *Transactions Faraday Society*, Vol. 27, Dec. 1931, pages 767-771.

Contains 8 references. When prepared at room temperature from $FeCl_2$ and Ca $(OH)_2$, $Fe_2O_3.H_2O$ has the same crystal structure as γ-hydrate. On heating in the temperature range 250°-300° C., it is converted to the cubic form, and in the range 500°-600° C., to the rhombohedral form, there being no definite transition temperature. The size of the crystals at the various temperatures is given. PRK (10)

Contribution to the Economic Heat-Treatment of Steel. (Beitrag zur wirtschaftlichen Wärmebehandlung des Stahles.) ERNST BOCK. *Maschinenbau*, Vol. 10, Feb. 19, 1931, pages 127-132.

The author shows how the annealing and hardening processes used increase the quality and value of the resultant material and how the costs of heat treatment can be reduced. MAB (10)

Heat-Treating Methods and Costs. ERNEST FOSTER DAVIS. *S. A. E. Journal*, Vol. 29, Dec. 1931, pages 474-475, 478.

Development of continuous automatic methods for annealing, carburizing and hardening steel have made quality much more uniform than it could be when it depended upon the skill, attention and faithfulness of workmen. Modern furnaces carry out a scientifically planned cycle more accurately than workmen can, so that the depth of case, for instance, can be held to closer limits. The cost of the processes are greatly reduced; and far greater economies result from the increased uniformity of the product, which makes machining easier and reduces the number of defective parts. The choice between sources of heat should be made only on the basis of results. Developments in forging are prophesied that will provide far greater accuracy than in present methods and will eliminate the formation of scale. Continuous carburizing furnaces using gas as the carburizing medium are also now in the process of being developed. Estimates show that carburizing can be done satisfactorily at a cost of about 0.6 cents/lb. in this manner. WAT (10)

Heat Treatment for Large Forgings. W. J. MERTEN. *Heat Treating & Forging*, Vol. 17, Sept. 1931, pages 870-871, 875.

A general discussion of improving the quality of forgings of large mass and considerable weight by proper heat treatment. Tempering and quenching of such forgings require the utmost care in uniformly slow heating in order to avoid incipient failures by the formation of surface fissures due to warping and severe local straining during heating. In the heat treatment of large forgings, carbide dispersion or relocation is not as important as orderly grouping of alloying elements and metalloids other than iron carbides and the Fe-C thermal and constitutional equilibrium diagram is only of secondary importance. The temperature zone of maximum solid mobility of components is, however, of the greatest importance in the heat treating practice for large forgings. Ha (10)

Hardening (10a)

Electric Eye Means Accurate Heat Treatment. *Metal Progress*, Vol. 21, Jan. 1932, pages 43-45.

Describes the new process of the Thompson Products Co. for spot hardening of gas engine valves. The operation was formerly done with an oxy-acetylene torch controlled by the judgment of the operator. Electric heat is now applied under the control of a photoelectric cell sensitive to 15° F. The new heating and control has resulted in a superior product at reduced cost. WLC (10a)

Selecting and Hardening High-Speed Steel. ALFRED HELLER (Hercules Electric Steel Corp.). *American Machinist*, Vol. 74, Apr. 23, 1931, pages 635-638; Apr. 30, 1931, pages 685-688; May 7, 1931, pages 726-728.

3 W- and 2 Co-steels were tested. All were drawn at 1050° F. for 1 hr. Hardness readings are plotted on curves which show that hardness increases with the quenching temperature at a nearly uniform rate up to 2350° F. From 2350° to 2425° F., the rate of increase is lower. Co-steels harden at lower temperatures than the W. Effect of soaking at various temperatures was tried. Soaking for one min. at 2250° F. gives the same hardness as 2300° F. without soaking. The lower temperature gives as good or better physical properties and hardening is more accurately controlled when using a short time soaking period and the lower temperature. Tougher and harder W-steels are made at 2250° F. with soaking for 1-2 mins. than at higher temperatures without soaking. Co high-speed steels are affected less by soaking at the hardening temperature or by overheating. Tempering is best done at 1050°-1075° F. and held at that temperature for 30 mins. Expansion takes place from 900°-1150° F. due to γ-Fe being converted to α at these temperatures, especially above 1000° F. RHP (10a)

Theory and Practice of Steel Hardening. (Zur Theorie und Praxis der Stahlhärtung.) FRANZ WEVER. (Düsseldorf). *Archiv für das Eisenhüttenwesen*, Vol. 5, Jan. 1932, pages 367-376.

Presented at meeting of Verein deutscher Eisenhüttenleute, Nov. 28, 1931. Includes discussion, 11 references, 20 diagrams and illustrations. The transformation of austenite proceeds in three entirely different temperature stages, each stage showing a different range of stability. New heat treatment processes are the natural result of these observations since the possibility is offered of converting steels from the pearlitic stage into the far more stable austenite-region, in order to reheat or cool further by gradual annealing, improving, or hardening operations. This assumes the stopping time in any stage to be according to definite cooling rates; for this purpose a series of ordinary hardening reagents was examined with respect to their cooling properties on steels in both the pearlite and martensite regions, showing excellent results. Groups of various hardening reagents are easily formed. GN + DTR (10a)

Annealing (10b)

Varies Annealing Temperature by Induction Regulator. R. W. MILLER. *Steel*, Vol. 88, Jan. 29, 1931, pages 38-40.

Discusses the general design, constructional features and accessory parts of several types of electric annealing furnaces made in Baden, Switzerland. Temperature control is obtained by the use of an "induction regulator" which raises or lowers the input voltage of the furnace from zero to double that of the line voltage. JN (10b)

Anneals High-Speed Steel in Pit-Type Furnace. W. S. SCOTT. *Steel*, Vol. 89, Sept. 17, 1931, pages 35-36.

Description of furnace and temperature control. In this electrically heated furnace a heat is being obtained in 24 hours; 7 hours heating, 17 hours cooling; a gas furnace required 60 hours. Ha (10b)

Continuous Strip Annealing Process and Fundamentals of Heat Transfer in Continuous Strip Furnaces. O. JUNKER. *Metals & Alloys*, Vol. 2, Dec. 1931, pages 352-354.

Translated by W. Adam (Ajax Electric Co.) from *Zeitschrift für Metallkunde*, Vol. 23, Apr. 1931, pages 124-125. Electrically heated continuous strip annealing furnaces are described for treatment of brass strip. WLC (10b)

The Annealing of Metal Strip in the Continuously-Operated Electric Furnace. *Metal Industry*, London, Vol. 38, June 26, 1931, pages 641-643.

Brass strip is annealed in horizontal and oblique electric furnaces. Automatic pickling, washing and drying units may be used with the latter type furnaces. Current consumption is around 100-130 KWH/ton. PRK (10b)

On the Annealing Brittleness. SOJI MAITA. *Tetsu to Hagane*, Vol. 17, No. 9, 1931, pages 1042-1046.

"Annealing brittleness" is a term given by the author for the phenomenon that steel slowly cooled through the entire temperature ranges in the process of annealing is brittle, compared with that rapidly cooled from a temperature slightly below the Ar_1 point, with an amplified meaning of the "temper brittleness." Several specimens of carbon steels, a Ni-steel, a Ni-Cr steel and a Ni-Cr-Mo steel were previously heated at 900° C. for 1 hr. and quenched into oil. These specimens were annealed at a temperature slightly above the Ac_3 point (marked by H), or above the Ac_1 point (marked by L), and cooled slowly in furnace to room temperature (marked by F) or quenched into water during cooling at a temperature slightly below the Ar_1 point (marked by Q), for which the Izod impact tests were carried out, and their microstructures were observed. In all cases, specimens F had a smaller impact value than specimens Q and their susceptibility to brittleness, ie., the value of $\frac{Q-F}{Q}$ was largest in the Ni-Cr steel. Furthermore, specimens H were more brittle than specimens L and, hence, the toughness was largest in specimens LQ (i.e., annealed at low temperature and quenched during cooling), followed by specimens LF, HQ and HF in order; here, it is noticeable that a specimen which is annealed at a low temperature above the Ac_1 point and slowly cooled has a larger impact value than that annealed at a high temperature and cooled from a temperature below the Ar_1 point. In microstructure, a small amount of carbide, separated in the grain boundaries of ferrite by the solubility change below the Ar_1 point, is observable in specimens F, but none in specimens Q. Also, crystal grains are coarse in specimens H, while they are fine in specimens L. From these results, it is concluded that the annealing brittleness is due to the 2 causes, i.e., coarsening of crystal grains and precipitation of carbide, the former being more effective. In order to eliminate the annealing brittleness, specimen should be annealed at a low temperature above the Ac_1 point and then be cooled rapidly below the Ar_1 point. ST (10b)

Use of Hydrocarbon Gases for Bright Annealing of Metals. E. G. DE CORIOLIS & R. J. COWAN. *American Gas Association Monthly*, Vol. 13, Oct. 1931, pages 457-459.

Some metals may be maintained bright very easily during heat treatment; the absence of free oxygen is all that is required. In zinc-bearing metals, difficulty arises from the volatility of zinc at annealing temperatures and which seems to be coincident with the liberation of occluded gases that are oxidizing and form a scale of mixed oxides that tarnish the alloy. This fact prevents the use of ordinary neutral or reducing atmospheres for this work. It was found that such metals could be made bright in an atmosphere of hydrocarbon gases under certain conditions. In such an atmosphere the minimum bright annealing temperature was 1250° F. This was too high for most annealing work. It was found that if the metal were drawn through this atmosphere at such a rate as never to attain this temperature the bright annealing reaction would continue only if the gas were held at the minimum of 1250° F. At this temperature, the hydrocarbon has cracked with the liberation of free C and H. Further study indicated that it was the H which was the active bright annealing gas. This was proved by the use of pure H and of ammonia under the same conditions, for the reactions took place in exactly the same way. Above 1250° F. in the presence of a suitable catalyst, the hydrogen becomes activated and has a power for reducing oxides not evident below that temperature. Using these ideas, a process has been developed for bright annealing wire or strip in strand form. It is applicable to ferrous and non-ferrous metals. RJC (10b)

Furnace Atmosphere Governs Bright Annealing Action. R. J. COWAN. *Steel*, Vol. 89, Aug. 13, 1931, pages 34-38.

The various atmospheres, such as H, N, CO_2, hydrocarbons, are discussed with respect to their influence of keeping metal surfaces bright during annealing. The tests have developed 2 methods, one, based on the breakdown of a hydrocarbon gas seems particularly well adapted for the annealing of metals in form of strips or wire. The other method uses flue gas and methanol and is well suited for annealing of stampings or other bulky materials which may require a lower temperature anneal. Ha (10b)

Case Hardening & Nitrogen Hardening (10c)

Deep Carburizing with Liquid Carburizers. (La cementazione profonda con cementi liquidi.) I. Musatti & L. Dainelli. *La Metallurgia Italiana,* Vol. 23, Nov. 1931, pages 1015-1028; *Giesserei mit Giesserei-Zeitung,* Vol. 18, Dec. 4, 1931, pages 922-923.

Baths such as 56% NaCN, 22% NaCl, 22% Na_2CO_3; 70% $BaCl_2$, 20% NaCl, 10 $CaCN_2$; and a "mixed bath" containing NaCN and KCN in the ratio of 4:1 and $CaCN_2$, diluted with suitable quantities of other salts, were used in carburizing steels of about 0.15% C, 3 to 4% Ni and 0.7 to 1.5% Cr. The straight cyanide bath could not be used above 880° C, while the cyanamid bath was used at 880°-930° C., but gave only slight increase in rate of carburizing at the higher temperature. The mixed bath could be used at 930° C. without the fuming or swelling encountered with the others, and its rate of carburization was much increased at the higher temperature. The straight cyanamid bath gave the poorest results of all as to depth of case. The scleroscope hardness at the surface was much lower (75-85) than that obtained with solid carburizers (90), but the layers at 0.2 to 0.3 mm. below the surface were harder (92-94) with the baths containing cyanide. The cyanamid bath produced greatest hardness at the surface but the hardness gradient fell rapidly. The mixed bath at 930° C. gave, in 2 hours, a scleroscope reading of 83 at the surface, 93 at 0.3 mm., then falling to 65 at 1 mm. In 3 hours, it gave 75 at the surface, rising to 96 at 0.6 mm. and falling only to 85 at 1 mm. The 2 hour case had 0.91% C, 0.19% N in the first 0.1 mm. layer, the same carbon in the second but the N fell to 0.05%; at greater depths, the C and N curves were practically straight lines, falling to 0.30% C and 0.10% N at 1 mm. The presence of KCN as well as NaCN and that of $CaCN_2$ are credited with causing the depth of case with the mixed bath. The exact composition of the mixed bath is not given. Repeated impact notched bar tests on the core material and on specimens carburized to 0.5 and 1 mm. with the mixed bath and with an ordinary solid carburizer plotted between energy of blow and number of blows to break, show all 3 curves crossing. At the highest stresses, the order of life is core material, solid carburized, mixed liquid bath carburized. At the lowest, the order is reversed. Contains 34 references, 17 figures, 8 tables. Nitriding of Iron and Iron Alloys. II. (Ueber die Nitrierung von Eisen und Eisenlegierungen. II.). O. Meyer & R. Hobrock. *Archiv für Eisenhüttenwesen,* Vol. 5, 1931, pages 251-260.

Report of the Institute of Ferrous Metallurgy at the Technische Hochschule Aachen. 30 references. The paper continues the previous investigation by W. Eilender and O. Meyer, *Archiv für Eisenhüttenwesen,* Vol. 4, Jan. 1931, pages 343-352, reviewed in *Metals & Alloys,* Vol. 2, Sept. 1931, page 177. Electrolytic iron was nitrided at 550° C. for 2, 5, 8, 11, 15½, 21½, 30, 40 and 87 hrs. The dissociation of ammonia was kept below 10%. The hardness was determined at various depths of the case with a Firth hardness tester, but the readings were converted to Brinell. In plotting the hardness against the depth of case, a maximum of hardness was observed on every curve for the various nitriding temperatures. No strict relation between this "spitzenhärte" and time of nitriding seems to exist. (This occurrence of a maximum on the hardness-depth curve has been observed by the authors for the first time, but it may be pointed out that an indication of such an occurrence was observed and described in the simultaneously published paper by O. E. Harder and G. B. Todd, *Transactions American Society for Steel Treating,* Vol. 19, Nov. 1931, pages 41-65. In 2 of the samples there also was the hardness at a depth of about 0.003 to 0.004 in. somewhat higher than at the surface). In nitriding at higher than the above mentioned temperatures the maximum of hardness is found at greater depths but, when the nitrided specimens are annealed for some time at 550° C. or higher temperatures, the location of maximum hardness in the specimen is shifted in the other direction. The nitrogen contents at maximum hardness are very far below those which have been given as the solubility limit of nitrogen in α-iron at room temperature. To study the causes of nitrogen hardness, X-ray pictures were taken of successive layers of nitrided specimens 0.1 mm. thick, but the results are not yet sufficient to find a reasonable explanation. Similar experiments were carried on on Fe-Al alloys containing 0.09%, 0.17%, 0.40%, 0.70%, 0.80%, 1.08%, 2.08% and 3.66% Al and nitrided for 48 hrs. at 550° C. The surface hardness after a steep increase with increasing content of Al attains a maximum at 0.8% Al, to decrease again at higher contents without showing a continuous curve but having another maximum and 2 minima. The hardness-depths curves were also plotted. Maximum hardness occurs below the surface at concentrations above 0.70% Al. X-ray patterns were taken of layers of a 0.8% Al alloy nitrided for 24 hrs. at 550° C. The hardness of nitrided Fe-Al alloys is due not to a single effect but to the following reactions. (1) The largest increase of hardness is caused by the hard and insoluble compound AlN in blocking the gliding planes. (2) A smaller extent of hardness is due to the deformation of the iron lattice by AlN. (3) Nitrogen reacting with the iron matrix increases the hardness in the fields of low concentrations of nitrogen, i.e., in greater depths of the specimen. (4) At higher contents of Al, the formation of layers of precipitation can cause an increase of hardness. GN (10c)

Nitrided Valve Guide Bushings for Airplane Motors (Nitrierte Ventilführungsbüchsen für Flugzeugmotore). J. Wizemann. *Deutsche Motorzeitschrift,* Vol. 8, May 1931, page 198.

Points out the technical difficulties inherent in the valves of airplane motors and discusses the advantages of nitrided valve guide bushings. EF (10c)

Carburizing in Electric Furnaces. (La cémentation au four électrique). *Journal du Four Electrique,* Vol. 40, Dec. 1931, pages 477-480.

A translation of an article in *Machinery* dealing with the advantages of electric furnaces for carburizing purposes and giving production figures from the installation of David Brown and Sons, Ltd. JDG (10c)

Case-Hardening with Liquid Carburizing Agent. *Engineering,* Vol. 131, June 19, 1931, page 803.

Describes new case-hardening process in which a liquid is used, Carbonal, which has a vegetable base and is rich in hydro-carbons. Illustration shows the apparatus and electric furnace used in the process. LFM (10c)

Moisture in Gas has Effect on Carburizing Action. *Steel,* Vol. 88, Mar. 5, 1931, pages 59-63.

Gas used for carburizing should first be dried thoroughly as the moisture contained in it often prevents satisfactory carburization. The steel to be carburized should be first exposed to CO_2 gas for a brief period as this gas serves to remove from the steel a dead surface film which retards the penetration of carbon. Suitable burners for gas carburization are described briefly. Ha (10c)

The Development of Continuous Nitriding. R. J. Cowan. *Heat Treating & Forging,* Vol. 16, Oct. 1930, pages 1277-1280.

A general discussion of nitriding and detailed information regarding the process as carried out in continuous furnaces. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 132. Ha (10c)

Nondeforming Alpha-Delta Carburizing Steel. A. B. Kinzel (Union Carbide and Carbon Research Lab.). *American Society for Steel Treating, Preprint* No. 15, 1931, 10 pages.

Paper read and discussed before the Boston Convention of the Society, Sept. 1931. The author attributes the distortion experienced in the heat treatment of carburized work to the changes in volume involved in the phase changes of the core material. In line with this idea, an alloy steel for carburizing has been developed which has no α-γ transformation. The well known loop of the γ-Fe range in Cr steels is made use of with similar conditions in the diagrams for Si and V. By proper combination of these alloys, a steel of low alloy content can be produced at reasonable cost which will have no transformation in the core. At carburizing temperatures, α-Fe will slowly absorb C; the higher C thus attained shifts the loop so that the γ-transformation takes place and C is rapidly absorbed by the austenite. Tests have demonstrated that this combination results in a very minimum of distortion on quenching and the core properties are improved by the alloy additions. The compositions and physical properties resulting from this type of steels are given. WLC (10c)

Malleableizing (10g)

Black Spots in Malleable (Quelques remarques sur un défaut de fonderie: "le noir de la malléable). M. Kagan & R. Deprez. *Congres International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 875-877.

Black patches in white iron for malleabilizing are considered to be due to gas penetrating into heat-cracks. The cracks form through improper design of the casting, wrong gating, or lack of precautions in molding. HWG (10g)

Malleable Iron with Black Core in the Cupola Furnace (A propos de fonte malléable a coeur noir au cubilot). Ch. Kluijtmans. *Revue Fonderie Moderne,* Vol. 25, Sept. 10, 1931, pages 327-328.

The author maintains that a good malleable iron can be produced in the crucible as well as in the reverberatory furnace, provided that all cementite is decomposed in fixed cementite before the thermal treatment has gone too far. Ha (10g)

Pots for Malleableizing. (Tempertöpfe.) W. Bernhard. *Zeitschrift für die gesamte Giesserei Praxis,* Vol. 53, Jan. 24, 1932, pages 44-45.

Brief description on production and composition of pots for malleableizing. GN (10g)

Effect of Molybdenum on Graphitization of White Cast Iron. W. H. Jennings, Jr. & E. L. Henderson (Iowa State College). *Metals & Alloys,* Vol. 2, Oct. 1931, pages 223-225.

5 references. The authors report a study of the effect of Mo up to 5% in malleable iron. Its presence results in a grain refinement and rates of graphitization are inversely proportional to the amount of Mo present. Mo increases the hardness, toughness and tensile strength of malleable iron. WLC (10g)

Malleable Iron—Recent Progress. H. A. Schwartz (National Malleable & Steel Castings Co.). *Metals & Alloys,* Vol. 2, Sept. 1931, pages 143-149. 36 references.

The author discusses the compromise between high and low C, high and low Si with consideration of the size of section in making malleable iron. The alloy must freeze without precipitation of graphite but must graphitize in a reasonable time by treatment. The annealing cycles necessary to achieve complete and satisfactory graphitization are discussed. It is stated that malleable iron is the most readily machinable ferrous alloy known. The differences between European and American malleable are pointed out, white heart and black heart, respectively, are the most prevalent types of malleable made in the 2 continents. The effect of other elements on malleable are discussed as to their effect upon graphitization. Al, Zr, U, Ti, Ni, Si, B in small amounts only, Cu and Co only slightly, accelerate graphitization. Cr, Mn, V, S, Se, Te, B over 0.10%, Mo in fair amounts, Sb and Sn are retarders of graphitization. The various views on the mechanism of graphitization are discussed. Applications of malleable castings are discussed. The author gives 8 cautions to engineers using malleable. WLC (10g)

The Annealing of Malleable Iron (Das Glühen von Temperguss). V. Wollenigh. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Nov. 6, 1931, page 868.

In order to shorten the duration of annealing, the temperature is increased to 1000° C., the content of C is reduced considerably and that of Si is increased. The content of P must not exceed 0.2%; S must be kept as low as possible. The content of Mn is calculated from % Mn = % S × 1.7 + 0.2. Under these conditions, the annealing takes, in all, about 35 to 40 hrs. Samples showed a tensile strength of 35-40 kg./mm.² and 7-10% elongation. This annealing process can also be applied for black-core malleable castings. Ha (10g)

JOINING OF METALS & ALLOYS (11)

New Developments in Pipe Joints (Neuzeitliche Rohrleitungsverbindungen). E. H. A. Thau. *Gas- und Wasserfach,* Vol. 74, Oct. 17, 1931, pages 861-866.

Abridged in *Gas World,* Vol. 95, Dec. 5, 1931, *Coking Section,* pages 12-14. The recent developments in the gas, water and oil industries have led to the increase in the complexity of the network of transmission lines. The connecting of individual pipes or systems with others requires precaution and care. The chief causes for leakages occurring in those connections were investigated and it was concluded that the joints should be required to be of specified quality. The article discusses flanges, screws, screw-caps and weld seams, the improvement of welds in steel tubes and in cast tubing, taking into consideration pressure, variation in temperature, gravity, etc. Several commercial types of joints and materials are described. MAB (11)

Welding or Riveting in Chemical Equipment Manufacture? (Schweissen oder Nieten im Chemischen Apparatebau?) H. Buchholz. *Chemische Fabrik,* Vol. 4, Oct. 21, 1931, pages 413-414; Oct. 28, 1931, pages 421-422.

Contains 4 references. It is shown that, in welded chemical equipment, corrosion takes place along the riveted seam and in the rivets due to strains in the metal. The corrosive attack assumes the same pattern as the strains in the metal. This can be reduced by thoroughly annealing the metal. Acids and other solutions which tend to dissolve the metals attack them in the form of grooves, while NaOH, $Ca(NO_3)_2$, $NaNO_3$ and NH_4NO_3 produce intercrystalline corrosion. Photographs of rivets attacked by chemicals are shown. For these reasons, riveted construction is not recommended for chemical equipment. Good quality welding is stronger, more corrosion-resistant and cheaper. Oxy-acetylene welding, together with hammering to form small grain size and exclude gases and slag, produces good results. It is better to anneal the parts after welding. For cast iron, oxy-hydrogen welding is better. Electric welding has not been used much for chemical equipment as it is difficult to obtain perfect joints free from inclusions. CEM (11)

The Soldering of Brass and Copper Tubes in Sanitary Plumbing. (La Soudure des Tubes en Laiton et en Cuivre dans les Installations Sanitaires.) *Cuivre et Laiton,* Vol. 4, Dec. 15, 1931, page 551.

Description of methods of joining tubes by soldering and brazing. Ha (11)

Soldering and Welding Aluminum and Its Alloys. (Das Löten und Schweissen von Aluminium und seinen Legierungen). Ernst Weber. *Giesserei-Zeitung,* Vol. 27, Feb. 1, 1930, pages 72-76.

Al and its alloys are difficult to solder because (1) the thin skin of thermally resistant and chemically inert oxide hinders a firm alloying of the metal and solder, (2) the high specific heat and thermal conductivity of Al cause in spots a "quenching" of the liquid solder, and (3) the strong electropositive nature of the metal sets up reactions in the presence of liquids or moist air. Most modern Al solders consist principally of Sn with some Al and Zn. Many contain also Sb, Bi, Cd, Cu, Pb, Ni, Ag and other metals. Soldered joints are tested in steam, boiling salt solution, or in boiling H_2O for several days. The tensile strength is 5 kg./mm.^{2}, which is lower than that of Al. In order to meet chemical and mechanical specifications, autogenous welding is recommended. Al is one of the most weldable of metals, if the following characteristics are kept in mind: (1) low resistance against oxidation, (2) high coefficient of expansion, (3) high thermal conductivity, (4) low melting point, (5) low tensile strength at high temperatures, (6) tendency to warp. Modern fluxes consist of alkaline chlorides, fluorides, bisulphates, etc. A slightly reducing oxy-acetylene flame gives good results. Welded joints should be guarded against too rapid cooling. (11)

Brazing (11a)

Brazing by Resistance Method. W. C. Reed, M. Unger & G. E. Gifford. *General Electric Review,* Vol. 33, Oct. 1930, pages 568-570; *Brass World,* Vol. 26, Oct. 1930, pages 267-269.

Many metals, such as Cu, Ag, Ni, steel and their alloys, can be brazed electrically. See *Metals & Alloys,* Vol. 2, Mar. 1931, page 70. (11a)

Copper Brazing in Controlled Atmosphere Furnaces. H. M. Webber (General Electric Co.). *Metals & Alloys,* Vol. 2, Nov. 1931, pages 284-287.

The technique of copper brazing in an atmosphere of hydrogen is described. Applications of the method to the joining of metal golf shafts, carboloy tips to various holders, refrigerating machine parts and other parts are described. Hydrogen reduces any oxides formed and the very fluid copper flows readily into all joints making a sound connection. WLC (11a)

Brazing Carbon Steel. Burton W. Wheeler. *Power,* Vol. 74, Oct. 6, 1931, page 503.

To braze C steel for tempering, Cu only is used instead of Cu-Zn spelter. The parts must be heated to higher temperatures than for an ordinary job. After brazing, the C steel should be annealed, hardened and drawn. AHE (11a)

Brazing with a Self-Fluxing Alloy. C. J. Snyder. *Machinery,* Vol. 37, June 1931, pages 760-762.

Parts are brazed together in an electric brazing machine by the use of a self-fluxing phosphor-copper alloy which thoroughly fluxes the joint. Methods of making different types of joints are explained. Ha (11a)

Lowering of the Over-head Expenses in Gas Plants and Water Plants by the Utilization of the Welding Technique. I. Hard Soldering (Senkung der Betriebskosten in Gas- und Wasserwerksbetrieben mit Hilfe der Schweisstechnik. I. Hartlöten). F. Wechwerth. *Gas und Wasserfach,* Vol. 74, July 18, 1931, pages 678-684.

The economical utilization of the oxy-acetylene torch in connection with a bronze solder (59-63% Cu, 36-40% Zn, 0.5-1.5% Sn) for repair work in gas plants and water plants is given at length and a great number of practical examples are presented in 24 illustrations. The reduction of the soldering temperature of the torch is stressed in the discussion of the procedure of hard soldering. EF (11a)

Silver Brazing of Monel Metal and Nickel. R. J. McKay. *Western Machinery World,* Vol. 22, June 1931, pages 256-257.
Though bearing the name of "solders" silver solders are strictly speaking brazing or welding metals. They lie in between soft solders and welding metals. A silver solder, developed in conjunction with the International Nickel Company and recommended by Handy & Harman, known as type RT, flows at the temperature of 1325° F. and is recommended for joining Monel metal and Ni. Boric acid and borax may be used as a flux. WHB (11a)

Soldering (11b)

Soft Solders and their Application. G. O. Hiers (National Lead Co.) *Metals & Alloys,* Vol. 2, Nov. 1931, pages 257-261, 277.
47 references. An equilibrium diagram for Pb-Sn system is given and discussed. The addition of small amounts of Sb results in a "peritectoeutectic point" at Pb 40%, Sn 57½% and Sb 2½% with a reaction temperature of 188° C. A.S.T.M. specification for soft solder cover 11 compositions varying from 31-63% Sn, up to 2% Sb and balance Pb except for permissible impurities. British Standards list 8 solders of similar composition and one of 95% Sn and 5% Pb, permissible Sb up 0.3%. The nature of a soldered joint is discussed; alloying is desirable but not essential. A deposit of Pb acting as a solder is obtainable on Al by heating lead chloride in contact with Al; no alloy results. A solder must be adhesive. The rule for soldering is cleanliness of the metal. Mechanical and etching methods for cleaning are discussed. Fluxes are discussed: those which act to prevent oxidation and those which act as a scavenger, also $ZnCl_2$-NH_4Cl flux acts in the latter way. Method of application of solder varies with the size, shape and nature of the parts being soldered; the speed of soldering and the mechanical properties obtained in the joint depend upon the method employed. Methods are discussed under wiping, soldering tool or "iron," blow torch, sweating, and dipping. Modifications or combinations are worked to advantage for certain jobs. The surfaces to be soldered must be brought to the solder temperature. Special applications of these methods are described. Curves show the mechanical properties to be obtained from soldered joints; one shows effect of temperatures and "creep." WLC (11b)

Brazing or Hard Soldering Metals with Silver Solders. A. Eyles. *Sheet Metal Industries,* Vol. 5, July 1931, pages 182-186.
The application of silver solders is possible on brass, bronze, copper, Monel metal, nickel, iron, steel and stainless steel. The melting points of silver solders vary from 1250°-1600° F. The most reliable flux is fused borax. Coarse grained structure and distortion result from overheating. AWM (11b)

Silver Solders and Their Use. R. H. Leach (Handy & Harman.) *Metals & Alloys,* Vol. 2, Nov. 1931, pages 278-283.
The author reports a metallographic study of Ag solder joints with Cu, brass, Ni-Ag, Monel, and Fe. 4 solders of following compositions were studied:

Silver	20%	50%	65%	80%
Copper	45%	34%	20%	16%
Zinc	20%	16%	15%	4%
Cadmium	5%	....	....	....

The diffusion of the solder into the base metal was studied by holding soldered joints molten for periods up to 2 hours. Holes drilled in blocks of metal were filled with solder, covered with borax flux and held at several hundred degrees above the liquidus of the solders for various periods and examined under the microscope. The zone of diffusion was definite though shallow in cases where no superheat was applied. Superheat produces greater diffusion. Practical applications of Ag soldering are discussed. The use of fluxes and technique for elimination of "balling up" and pinholes are discussed. With proper handling high Zn solders will not cause pinholes. WLC (11b)

Special Solders. *Metallurgist,* Oct. 1930, pages 157-158.

Estimating Field-Welding on Multi-Story Buildings. *Engineering News-Record,* Vol. 108, Jan. 21, 1932, pages 94-95.
A study of the costs, time used, materials, and other economic details on 3 buildings, each 14 stories or over, in representative sections of the United States. Valuable tabulations and discussion are included. CBJ (11c)

Arc-Welding Progress that Tends to Eliminate the Human Factor. *Metallurgia,* Vol. 5, Dec. 1931, pages 35-36.
The shielded arc has made possible the production of welds that are just as reliable as riveted joints. Curves showing the correct ratios for Mn, Si and Al in welding rods are shown. JLG (11c)

Welding Qualities of Steel. Wilmer E. Stine. *Iron & Coal Trades Review,* Vol. 123, Dec. 11, 1931, pages 906-907; *Foundry Trade Journal,* Vol. 45, Dec. 24, 1931, pages 387-398.
A study was made of the various elements which affect the results in arc-welding including the steel used in the manufacture of shapes and plates as well as the electrode material. Curves are reproduced indicating Al, Si and Mn content of optimum arc-welding characteristics. In general it could be stated that aluminum oxides or any other non-metallic inclusion in steel which has its melting point between the melting point and boiling point of steel will cause slag holes or pits in the weld metal of electric-arc-welded steel unless it is fluxed with a material which lowers the freezing point below that of the steel. Al, Ag, Mn or any other deoxidizers having gas-solvent properties which are present in excess of the quantity necessary for chemical equilibrium with the oxygen present in the steel at a temperature slightly above the temperature of solidification may cause the formation of gas holes in the weld metal of arc-welded steel. OWE + Ha (11c)

Testing Steel Sheet for Weldability. *Metal Stampings,* Vol. 4, May 1931, page 414.
Describes a ready blowpipe test for determining the welding quality of steel sheet. JN (11c)

Report of Structural Steel Welding Committee. *Journal American Welding Society,* Vol. 10, Nov. 1931, pages 18-40.
Second installment of report of Structural Steel Welding Committee of the American Bureau of Welding. Consists of Sections 3, 4, and 5 which deal with welder qualification test results, adjustment of length and cross section of welds, and program test results. Many photographs of typical failures are shown together with graphs showing test data. TEJ (11c)

Reduction of the Operating Cost of Gas and Electric Works by Welding Processes. I. Hard Soldering (Brazing). (Senkung der Betriebskosten in Gas- und Wasserwerksbetrieben mit Hilfe der Schweisstechnik.) *Das Gas- und Wasserfach,* Vol. 74, July 18, 1931, pages 678-684.
Discusses the welding of various parts such as casings in motor frames, casing for diaphragm rims in centrifugal pumps, distance pieces for tubing, water meter flanges, hubs and headers of cog wheels, valve flanges, water jackets in compressors, bell crank levers, valve discs in diaphragm pumps, etc. Welding is done with bronze rods of a composition of 59-63% Cu, 36-40% Zn and 0.5-1.5% Sn. Investigations of failures, including tensile tests and microscopic examinations due to cracks and fissures are carried out. MAB (11c)

New Electric Welded Pipe Process Differs from American Practice. *Steel,* Vol. 88, Jan. 29, 1931, page 40.
A new process for the manufacture of welded pipe and tubing has been developed in Norway and is now in use in 5 European plants. This process permits the electric welding of hot rolled open seam tubing without pickling, cleaning or shearing at production speeds up to 80 ft./min. JN (11c)

Standard Tests for Welds. Revision of Bulletin No. 1, American Bureau of Welding. *Journal American Welding Society,* Vol. 10, Nov. 1931, pages 14-17.
Standard procedure for preparation of samples and test specimens, tensile test of base metal, tensile test of weld metal, tensile test of welds, bend tests of welds and shear tests of fillet welds. TEJ (11c)

Pullman Builds All-Welded Hopper Cars for C. G. W. *Journal American Welding Society,* Vol. 10, Nov. 1931, pages 5-7.
Reprinted from *Railway Age.* 5 70-ton hopper cars for coal transportation will each produce $400 more revenue/yr. than riveted cars, due to substantial saving of weight because of their all-welded construction. TEJ (11c)

Announces Production of 6 to 24 Inch Diameter Spiral Welded Pipe. *Steel,* Vol. 88, Feb. 19, 1931, page 47.
This is produced in 40 ft. lengths by the American Rolling Mill Co., Middletown, O., from coiled strip. 200 ft. in length The spiral seam is formed by feeding the flattened strip into the welding machine at an angle of 45°. This results in a straight, true-round, rigid pipe with smooth inside walls. The finished pipe is tested hydraulically. JN (11c)

WORKING OF METALS & ALLOYS (12)

Securing Quality in Steel Plate. J. Stewart Huston (Lukens Steel Co.). *Metals & Alloys*, Vol. 2, Oct. 1931, pages 209-213.

The author recounts experience in manufacture of plate steel. He discusses the quality of plate under the various operations melting, pouring, molds, heating, rolling, cutting and inspection. The applications of "open" and of "killed" steels are discussed as are the defects resulting in plate from faulty melting and casting. The effect of alloy content and the fabrication of structures from welded plate is discussed. WLC (12)

Melting & Refining (12a)

The Distribution of Non-Metallic Inclusions in Steel Ingots, and the Effect of Deoxidizers Upon the Distribution with Special Reference to Zirconium, Sodium and Calcium. (Die nichtmetallischen Einschlüsse in Stahl, ihre Verteilung im Gussblock und ihre Beeinflussung durch Desoxydationsmittel, insbesondere durch Zirkon, Natrium und Calcium). W. Zieler. *Archiv für Eisenhüttenwesen*, Vol. 5, Dec. 1931, pages 299-314.

The distribution of non-metallic inclusions in steel was determined in 50 heats of SAE 4140 of normal production and in other heats made in the electric furnace which had been deoxidized with zirconium, sodium and calcium. The amount and distribution was studied in all steels by counting the number of inclusions in an area of ½ in.^{2} of 5 × 5 in. billets, representing top, bottom and middle of the ingots. The results show that the non-metallic inclusions in the ingot are distributed as follows: Inclusions of oxides and silicates are most numerous in the bottom of the ingot and also show the largest dimensions there. Inclusions of sulphides coincide with the segregations and, therefore, are more numerous in the top of the ingot. The occurrences during solidification and their effect upon the distribution of the inclusions are considered. The formation, within, and the elimination of non-metallic inclusions from the liquid steel bath are essentially affected by the ratio of manganese to silicon during the melting down and the working period of the heat as well as the state of the melt at the time of the first additions of the alloying elements. A high content of manganese at the end of the melting-down period decreases the number of inclusions. A high content of silicon at the end of the melting-down period increases the amount of the silicate inclusions. If an alloy containing larger amounts of silicon and carbon is added to an incompletely deoxidized steel bath, silicon oxidizes to silica and part of the carbon, to carbon monoxide which, again, causes the formation of silica during a later addition of silicon. The formation of silicates is practically negligible in completely deoxidized heats. Deoxidation with silicon and manganese together is always preferable to a deoxidation with manganese only, since silicon and manganese form an iron-manganese silicate with a low melting point which can be better removed. It is advisable to add manganese before the addition of silicon so that in adding ferro silicon a sufficient amount of manganese oxide is already present to form the iron manganese silicates. The influence of zirconium, titanium, cerium, sodium and calcium as deoxidizers was studied. Titanium prevents segregations without interfering with the cleanliness of the steel. TiO_2 lowers the melting point of the silicate slag and thus facilitates its elimination. Ti also forms the compound TiN thus eliminating nitrogen. Zirconium combines with S to ZrS_2 and with N to ZrN and decreases the number of non-metallic inclusions. The best results as to cleanliness of the steel are obtained when Zr is added to the ladle, although the number of nitride inclusions increases in this case. However the inclusions of ZrN are of a very small size and no impairing influence upon steel quality could be observed. Cerium increases the non-metallic inclusions in steel. Sodium is unsuitable as deoxidizer since it reacts explosively and makes it impossible to get a proper ingot. Calcium seems to be fit as deoxidizer. It decreases the oxygen content and the non-metallic inclusions in steel. 17 references. GN (12a)

A Thermal Study of an Open-Hearth Furnace. Wm. M. Henry & T. J. McLaughlin. *Engineering*, Vol. 131, June 1931, page 802; *Fuels & Furnaces*, Vol. 9, June 1931, pages 703-706, 716.

The Volatilization of Antimony in the Converter. (Ueber die Verflüchtigung des Antimons im Konverter.) W. Kroll. *Metall und Erz*, Vol. 28, Nov. 1931, pages 521-523.

Contains 2 references. Attempts to recover Cu from Cu-Sb slags by volatilizing the Sb in converters have failed because only a small amount of the Sb can be driven off. It is necessary to form Sb_2O_3 which is volatile, and which forms at 1150° to 2200° C. At lower temperatures Sb_2O_4 forms, which is not volatile. Conditions in the converter are not favorable as volatilization is reduced by the presence of basic materials such as PbO, MgO, Cu_2O and FeO. When FeS or CaO were added, volatilization was prevented entirely. A Cu-Sb slag was heated in a specially built steel retort in vacuum at 600° C. and over 50% of the Sb was volatilized. Sb may have been present in the slag as Sb_2O_3 or it may have formed in a secondary reaction from higher oxides with Cu_2O or small Cu particles. The process is not practical as Sb_2O_3 reacts with the steel retort wall. CEM (12a)

The Melting of Cast-Iron Rolls in the Electric Furnace (Das Schmelzen gusseiserner Walzen im elektrischen Ofen). L. Del Grosso. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Nov. 6, 1931, page 867.

The manufacture of finishing rolls, which are best made of a semi-hard cast iron with 2.5% C, has been found to give best results in the electric furnace. The rolls show denser and more uniform grains even in complex sections, a very fine and well distributed graphite and a pronounced pearlitic structure. Also, the mechanical properties were better than those of other materials. A 3-high mill equipped with such rolls gave a 32% higher production than when equipped with rolls from a reverberatory furnace. Ha (12a)

Casting & Solidification (12b)

The Craven Centrifugal Casting Machine. *Metal Industry,* London, Vol. 39, July 24, 1931, pages 83-84.

A description is given of the machine for centrifugally casting gear wheels, etc. PRK (12b)

On the Contraction of Copper-Tin Alloys. (Ueber die Schwindung von Kupfer-Zinn-Legierungen.) F. Böhm & F. Sauerwald. *Giesserei,* Vol. 17, Aug. 29, 1930, pages 841-849.

The contraction of various tin-bronzes on solidification after casting with varying conditions of cooling and in different gas atmospheres has been determined. See "Shrinking of Alloys," *Metals & Alloys,* Vol. 2, Nov. 1931, page 270. (12b)

Centrifugal Casting of Metals and Alloys. J. E. Hurst (Sheffield, Eng.). *Metals & Alloys,* Vol. 2, Oct. 1931, pages 196-205.

The author points out the difference in the solidification of the centrifugal casting, which solidifies from one side of the section whereas the ordinary casting solidifies from both sides and leaves a more or less open center. The author discusses the centrifugal casting of cast iron and the properties obtainable with and without alloys. Microstructure of centrifugal castings and segregation therein are discussed. The method is best adapted to the production of hollow cylindrical castings. Equipment for production of casting by this method is described and discussed. WLC (12b)

Pouring of Aluminum Billets. (Vergiessen von Aluminium walzbarren.) P. Pontremoli. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Nov. 13, 1931, page 883.

Electric furnaces with neutral atmosphere are most suitable for melting of Al bars, as the metal should not be heated above 730° C. on account of its great tendency to absorb gases. The metal should remain in the furnace at from 670 to 680° C. to let the gases escape; the temperature should be increased to 760° C. just before pouring and care be taken that the metal does not go into the ladle at less than 700° C. To avoid segregations the temperature of the ladle should be kept below 300° C. Titanium additions give a finer grain and increase tensile strength and corrosion resistance; all electrical properties are improved except conductivity. The best results are obtained at temperatures of 730° C. at the beginning and 700° C. at the end of pouring, and at 250° to 300° C. of the outer surfaces of the ladle. The velocity of pouring is about 10 kg. of Al per min. A few hints as to ratio of dimensions of billets to ladle or mold are given. Ha (12b)

Water-cooled Ingot Molds; Construction, Operation, Results. (Wassergekühlte Kokillen; Konstruktion, Gebrauch, Ergebnisse.) K. Scherzer. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Dec. 4, 1931, page 922.

The defects of molds for pouring brass ingots are discussed and a water-cooled mold of Junker is described which avoids these errors. Results with other metals are reviewed. Ha (12b)

A Method for Determining the Volume Changes Occurring in Metals During Casting. C. M. Saeger, Jr. & E. J. Ash. *Bureau of Standards Journal of Research,* Vol. 8, Jan. 1932, pages 37-60.

This paper reviews the methods which have been proposed and used for determining the various types of shrinkage undergone by a cooling metal. See also *Metals & Alloys,* Vol. 2, Feb. 1931, page 43. WAT (12b)

Automatically Operated Molds for Die Castings. (Selbsttätig arbeitende Spritzgussformen.) Albert Kaufmann. *Maschinenbau,* Vol. 10, Mar. 19, 1931, pages 206-209.

For some complicated die parts, special structures are necessary. They are described, and the complete operation is possible with a high hourly output. MAB (12b)

Die-Casting as a Recent Manufacturing Method for the Shaping of Copper and Zinc Alloys (Das Spritzgussverfahren als moderne Fabrikationsart für die spanlose Verformung von Kupfer- und Zinklegierungen). R. W. Schulze. *Dinglers Polytechnisches Journal,* Vol. 346, May 1931, pages 82-84.

The latest advancements of die-casting extended to the relatively high melting Cu alloys and Zn alloys are reviewed. EF (12b)

The Manufacture of Sand-Spun Pipes. *Engineering,* Vol. 132, July 24, 1931, pages 93-96, 108.

Outlines method of the Staveley Coal and Iron Company, Limited, Chesterfield for casting pipe centrifugally. In this process, pipes are produced in sand molds rammed in cast-iron flasks rotated longitudinally while the molten iron is poured in. Rotation is continued until metal is completely solidified. Pipe cast by this process are entirely free from blow-holes, cavities and solid inclusions. Photomicrographs are given showing structure of the metal at the outer, center and inner edge of a sand-spun pipe and a pit-cast pipe. In the former the metal is more compact, the size of the graphite plates is more uniform and the proportion of pearlite is higher than in the pit-cast pipe. Due to the fact that cooling is slow proceeding from the outer surface in contact with the sand, internal stresses are avoided; the whole strength of the metal is available to resist the normal working stresses. A very complete description of the entire process including many illustrations is given. LFM (12b)

Rolling (12c)

Methods Used for Electrically Preheating Sheet Mill Rolls. A. J. Whitcomb. *Rolling Mill Journal,* Vol. 5, Nov. 1931, pages 733-736.

Types of electrical heaters for resistance or induction heating are described. See "Comparison of Methods Used for Electrically Preheating Sheet Mill Rolls," *Metals & Alloys,* Vol. 3, Feb. 1932, page MA 45. Ha (12c)

Resistance to Deformation and Flow of Metal in Rolling. Erich Siebel. *Rolling Mill Journal,* Vol. 5, Mar. 1931, pages 205-208.

A study of the resistance encountered in the hot rolling of ordinary steel. Abstracted from a report of the Rolling Mill Committee of the German Iron and Steel Institute appearing in *Stahl und Eisen.* See *Metals & Alloys,* Vol. 2, Nov. 1931, page 270. JN (12c)

New Sheet Rolling Method Reduces Conversion Cost. *Steel,* Vol. 88, Jan. 15, 1931, page 41.

This article describes briefly and illustrates by diagram the respective lay-outs of 5 methods of hot rolling wide strip sheets. A chart is provided to show that 4 of these methods yield progressively greater savings in labor costs as compared to the first or old style Tipperary method. The article states that the newer methods are all in actual operation and available under license. JN (12c)

Rolling Temperature and Capacity of Merchant Mills. U. A. Peters. *Rolling Mill Journal,* Vol. 5, Sept. 1931, pages 601-602.

Mathematical expressions for determining the rolling pressure and time of rolling action in connection with the rolling temperature and capacity are derived. Mills finishing with a speed of 1500 ft./min. 12½% reduction. The determining factor for the speed of operation of a mill will be man-hours and kilowatt-hours per ton of steel rolled, factors which are better in the faster type of mills Ha (12c)

Electric Induction Roll Heating. R. J. Wean. *Rolling Mill Journal,* Vol. 5, Aug. 1931, pages 523-526, 558.

The disadvantages of preheating rolls by externally applied heat are explained and the construction of an induction coil laid around the rolls is described. The current induced in this manner in the interior of the rolls heats them up by hysteresis and eddy currents, and in exactly the same way as it takes place in actual rolling, that is the highest temperature is in the middle of the rolls decreasing towards the end. The advantages of this method are that the roll is gradually brought up to the required temperature by heat created in the roll itself; foundry and other interior stresses are relieved when the new roll is heated the first time, spare rolls can be kept hot in separate stands for immediate emergency, the heaters are put on Saturday nights, no attendance is needed; the rolls are covered to prevent radiation losses; the mill train always starts hot and power is saved by the reduced mill friction. The process is clean, and as it has a demagnetizing effect there is no likelihood of iron particles sticking to the rolls which might damage the sheets. Further, this electric load is used at off-times so that the current might be bought at a lower price. A roll heater takes about 50-60 KW. to raise the temperature of a pair of rolls 42 in. long by 30 in. diameter to 570° F. in 12 hours. Ha (12c)

Rolling Industry Adopting Many New Refinements. *Steel,* Vol. 88, Jan. 1, 1931, pages 289, 361.

The electrical developments in rolling mill practice for 1930 include the installation of one 4500 and two 5000 h.p. reversing motors in a universal slabbing mill, the first application of vertical motors in a continuous bar mill, the first installation of synchronous motors in hot tin mills, the development of automatic screw down control in rolling mills, the use of D. C. motor drives for bloom and slab shears, and the use of variable speed, shunt-wound motors for auxiliary mill drives. Other developments include normalizing furnaces, pack heating furnaces and levelers. JN (12c)

Electric Regenerative Drag for Sheet Mills. A. J. Whitcomb. *Freyn Design,* No. 9, Oct. 1931, pages 8-10.

A new electrical arrangement for the recovery of power, formerly lost in the friction drags used on sheet mill roll trains, resulted in a saving of $5400.00/yr. Ha (12c)

Effect of Loads on Ductile Metal. A. Nadai. *Rolling Mill Journal,* Vol. 5, Jan. 1931, page 54.

Paper presented at the annual convention of the American Society for Steel Treating. See "Concentrated Pressure and Some of its Applications to the Rolling Process," *Metals & Alloys,* Vol. 2, Oct. 1931, page 224. JN (12c)

Tin and Sheet-Mill Rolls—their Treatment, Performance and Premature Failure in Service. Eric R. Mort. *Blast Furnace & Steel Plant,* Vol. 18, July 1930, page 1180; Aug. 1930, page 1352; Sept. 1930, page 1502; Oct. 1930, page 1650; Nov. 1930, page 1732; Dec. 1930, page 1854; Vol. 19, Jan. 1931, page 156; Feb. 1931, page 298; Mar. 1931, page 446; Apr. 1931, page 582.

Improved Quality and Reduction of Costs in Forging. (Gütesteigerung und Kostensenkung beim Schmieden.) H. KAESSBERG. *Maschinenbau*, Vol. 10, Feb. 19, 1931, pages 125-126.
The size of the field to which forgings may be applied is discussed together with the limitations with which it is surrounded due to uneconomical production methods. MAB (12d)

Prevention of Internal Strains in the Material during Forging and Rolling of Ingot Steel. (Verhütung von inneren Stoffspannungen beim Schmieden und Walzen von Flussstahl.) AUGUST FRIEDRICT. *Maschinenbau*, Vol. 10, May 21, 1931, pages 358-360.
It is indicated and proved by tests how unequal thickenings and stretchings and internal strains caused by them are brought about during forging and rolling of ingot steel just cast from the pig. They are due to deformation. The ways by which these phenomena can be avoided is explained. MAB (12d)

Hot Pressed Bodies of Certain Shape (Konstruktive bedingte Pressteile). E. SEMMLER. *Deutsche Motorzeitschrift*, Vol. 8, July 1931, pages 264-270.
Refers to Cu-Zn and Al-Cu alloys applied for hot-pressed machinery parts, and covers tensile strength, corrosion and wear-resistance, additions of Ni, Mn, Al, Fe, economic considerations and practical applications which are illustrated by 12 figs. and which mainly refer to the automobile industry. EF (12d)

Machining by Pressure. JOHN H. FRIEDMAN. *S. A. E. Journal*, Feb. 1932, pages 80-83.
Standards of accuracy in forging are subject to constant revision. Accuracy depends upon the equipment used and the limit of forging accuracy was thought to have been reached because of the structural limitations in machines of existing types. However, the development of a new type of pressure machine has again caused a revision of the ideas of the accuracy attainable. Finish forging on this machine can be done on the heat remaining from forging or annealing, at a temperature below that at which scale is formed. Cold coining is also done with this machine with a high degree of accuracy and uniformity. What may be referred to as pressure machining of forgings eliminates roughing cuts, reduces the number of handlings and, in some cases, entirely eliminates further machining. Other economics resulting from uniformity are the facility with which work fits into chucks, jigs and hoppers, and the uniformity in weight of parts. The machine is also used for straightening and sizing malleable castings and for hot forging both ferrous and non-ferrous metals. WAT (12d)

Shearing & Punching (12e)

Dies for Trimming Steel Shells. CHARLES M. BREHM (Steel Products Engineering Co.). *Machinery*, Vol. 38, Nov. 1931, pages 183-185.
Dies are so constructed that, at a single stroke of the power press, the trimming member is oscillated in several directions so as to trim the part completely. Often notching and piercing can be combined with the trimming in one operation. Various die constructions are described. RHP (12e)

Newly Devised Trimming Unit Speeds Shearing Operation. *Steel*, Vol. 88, Feb. 26, 1931, page 44.
Description of a new combination side and end slitting machine developed by the Yoder Co. of Cleveland for use in the sheet, tin and steel drum industries. The side trimming shear is placed at right angles to the end trimming unit. JN (12e)

Extruding (12f)

The Extrusion of Metals. C. A. COLOMBEL. *Rolling Mill Journal*, Vol. 5, Aug. 1931, pages 539-542; Sept. 1931, pages 599-600; Oct. 1931, pages 667-670; Nov. 1931, pages 719-722.
Extrusion defects encountered with non-ferrous metals and alloys and the methods of avoiding them are discussed; examples are cited. The extrusion of hollow sections, especially that of round tubing, and the principles and practice employed in extrusion and drawing of non-ferrous tubing are discussed. Ha (12f)

What We Have Learned about Tungsten Carbide. F. W. CURTIS. *Machinery*, Vol. 37, July 1931, pages 867-869; Aug. 1931, pages 938-940.
By reviewing the present experiences with this material, 10 fundamental rules regarding proper use and methods are developed. Ha (12g)

Machine Tools for Light Metals. (Werkzeugmaschinen für Leichtmetallbearbeitung.) PH. KELLE. *Zeitschrift für Metallkunde*, Vol. 23, Nov. 1931, pages 309-313.
Tungsten carbide tools have proved most satisfactory for machining light metals containing Si (Silumin, Alusil); for other light alloys high-speed tool steel is satisfactory. Machine construction for machining light alloys is discussed in detail and illustrated by diagrams and photographs. The grinding of tungsten carbide tools is discussed. RFM (12g)

Tool Steel Specification. H. G. KESHIAN. *Metal Stampings*, Vol. 4, Nov. 1931, page 878.
The present methods of selecting a tool steel are critically reviewed. It is found that, while users of steel for mechanical and structural purposes have definite specifications of their requirements, the user of tool steel usually applies only general terms, such as "keen cutting edge," "toughness," etc. The possibility of the achievement of a similar definiteness in specifications for tool steels is questioned. Ha (12g)

The Broadening Field of Tungsten-Carbide Tools. J. A. MARKSTRUM. *Machinery*, Vol. 37, Mar. 1931, pages 511-515.
Milling cutters, drills, forming tools, counterbores, etc., are now fitted with carboloy tips; several are shown. Ha (12g)

Measurement of Cutting Pressure on Tool Cutting Edges. (Schnittdruck-Messung an Werkzeugschneiden). GEO. KEINATH. *Archiv für Technisches Messen*, section V132-2, 1931, page T6.
In order to measure the three components of the cutting pressures of a tool during cutting, that is the tangential, radial and axial component, the condenser measuring box has been devised. Two plane-parallel steel disks form an air condenser which is, in the box, placed between the tool and the support. The pressure exerted by the tool changes the airgap between the 2 steel discs and, as the condenser forms part of a tuned oscillating circuit, disturbs the balance in the latter. The current is amplified and can be used to make a record of the disturbing quantity which is a measure for the pressure. Method and curves are illustrated; literature references are given. Ha (12g)

Economics in Turning, Planing and Slotting. (Wirtschaftlichkeit bei Dreh-, Hobel- und Stossarbeiten.) W. FEHSE. *Maschinenbau*, Vol. 10, Feb. 19, 1931, pages 114-117.
The ways by which the quality of the work done in turning, planing and slotting can be improved with simultaneous reduction in costs is discussed. Making use of the coöperation of technical societies, use of technical literature, etc., is recommended. Certain problems concerning machines, tools and parts, can be solved by the Bureau on construction and machining. The advantages of using hard metal, high speed steel and hydraulically operated machines are pointed out, and examples are cited. MAB (12g)

An Investigation of Methods to Determine the Machineability of Malleable Iron Castings. O. W. BOSTON. *Proceedings American Society for Testing Materials*, Vol. 31, Pt. 2, 1931, pages 388-421.
Includes discussion. Extended discussion of machinability tests made by measuring the force required to cut in planing, milling and drilling. The ferritic surface of the casting machines with comparative ease. At 0.015 to 0.05 in., greater difficulty is encountered. At still greater depths, machining is easy. In discussion, Schwartz pointed out that the criterion of machineability in which the user of malleable is interested is tool life, not power consumption. HWG (12g)

Results of Cutting Pressure Measurements in the Machining of Various Kinds of Steels. (Ergebnisse der Schnittdruckmessung bei der Zerspanung verschiedener Stahlsorten). F. RAPATZ. *Stahl und Eisen*, Vol. 52, Jan. 7, 1932, pages 17-18.
Former tests showed that the cutting pressures are independent of the rate of machining, as well as of the boring depth, and decrease only slightly with the feed. Steels for automatics, with a small feed are easier to machine than soft ingot steels, since they require a small amount of shaping work. The writer contends that it is erroneous to use cutting pressure methods as a means of determining all effects. Following results were obtained in the comparison of the machinability of cast iron and steel by the use of high speed C steel and Widia metal tools, boring depth 4 mm. and 1 mm. feed.

	Cutting speed in m/min.		
	Steel of T.S.	Cast Iron of Brinell Hardness	
Tools made of	55 kg./mm.^{2}	203	180
High speed steel	37	18	28
Widia metal	82	108	over 200

Drawing & Stamping (12h)

The Production of Sheet Containers. Part II. S. D. Brootzkoos. *Metal Stampings,* Vol. 4, May 1931, pages 415-418, 425-426.
The author describes the following operations in the manufacture of tin cans: cutting tin sheet into required sizes for body blanks with automatic gang slitters; forming the can body in the can body making machine; soldering of the side seam; and forming the flanges on each end of the can body by means of the double end flanging machine. JN (12h)

Testing Drawing Qualities of Aluminum Sheets. R. J. Anderson. *Machinery,* Vol. 37, Mar. 1931, pages 494-495.
Tables which are developed from numerous cupping tests conducted to obtain data of aluminum sheets of different degrees of hardness and of varying thickness are given. The machine for making the cups is described. Ha (12h)

Deep-Drawing a Tubular Steel Spoke. E. H. Arnold. *Iron Age,* Vol. 128, Dec. 10, 1931, page 1534.
The subject is approached especially from an educational standpoint to show not only what has been done, but what can be accomplished with steel in producing a tubular steel spoke. In making the spokes, the author used ordinary soft cold rolled steel. The method used in making them is described. VSP (12h)

Cold Stretching Apparatus. (Kaltstreckapparat.) J. Blume. *Die Metallbörse,* Vol. 21, Jan. 1931, page 102.
The author points out the difficulties associated with the tapering of thin wires and calls attention to a recent device which hammers on the cone or point by means of two rotating halves of a mold. The apparatus is illustrated and explained. EF (12h)

Commercial Types of Power Presses. Part IV. Drawing Attachments Employed on Single Action Presses. Part V. Cam Drawing Presses. E. V. Crane (E. W. Bliss Co.) *Metal Stampings,* Vol. 4, May 1931, pages 409-413; June 1931, pages 497-500.
Drawing attachments are used on single action crank presses for holding the blank flat on the die during the drawing operation. The die employed is of the double action inverted type. Springs and rubber bumpers exert a blank-holding pressure which rises as the draw progresses. A uniform drawing pressure is highly desirable as this condition greatly reduces breakage losses. Several types of mechanical devices are designed to equalize or compensate for rising pressure. The air cushion is the most modern and most satisfactory type of blank-holding attachment as it permits the application of a uniform pressure throughout the drawing stroke.
Because of the great difference in the amount of work done by the two presses in blank holding, the double action press requires less power for a given drawing operation than does the single action press equipped with blank holding attachments. The author discusses several types of double action cam drawing presses and illustrates two types of presses and two types of double action dies used with them. JN (12h)

The Advantages of Uniformity in Cutting and Stamping Machines. (Vorteile der Vereinheitlichung beim Schnitt- und Stanzenbau.) A. Peterhans. *Maschinenbau,* Vol. 10, Feb. 19, 1931, pages 119-122.
The lines which are followed out in stamping technic are discussed and economically evaluated by a committee on economic production. MAB (12h)

Copper Wire Production on Continuous Machines. Wm. D. Pierson. *Wire & Wire Products,* Vol. 6, Dec. 1931, pages 470-472, 489.
The means for producing a desired quantity of copper wire and a method of estimating production results to be expected in drawing copper wire are discussed. The necessary equipment can be determined by taking into account carefully all the local conditions. An example illustrates the manner of procedure. Ha (12h)

Deep-Drawing Lubricants. Maurice Reswick. *Metal Stampings,* Vol. 4, Oct. 1931, pages 831-832.
The principal ingredients of deep-drawing lubricants are tallow, mineral oil, water and fillers like chalk, soapstone, mica, rosin, fire-clay, etc. Their characteristics and compositions are discussed. The principal requirements are strength of film, oiliness, adhesiveness and spreading, ease of cleaning, non-corrosiveness, stability and uniformity, odor and economy. They must not have any physiological effects on the machine operator. See also "Lubricants for Deep Drawing," *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 20. Ha (12h)

Measures of Die Performance. J. R. Longwell. *Wire & Wire Products,* Vol. 7, Jan. 1932, pages 16-17, 24-25, 28.
The various factors entering into wire drawing costs, as material drawn, die shape, lubricant, speed of drawing, are discussed, and a performance table is given for different gages. The cemented carbide dies are economical in use with proper considerations of the factors mentioned before. An economic factor of importance is the production per machine man. Ha (12h)

Comparison of Sheet and Strip Steels for Difficult Stampings. Edward S. Lawrence (Duraloy Co.). *American Society for Steel Treating, Preprint* No. 11, 1931, 21 pages.
Paper read and discussed at the Boston Convention of the Society in Sept. 1931. 53 references to the literature are cited. The differences in the manufacture of sheet and strip for deep and extra deep drawing automotive stampings are discussed. The defects and limitations of each material for this purpose are brought out. The adaptability of strip steel is discussed. Various physical standards now demanded by sheet and strip users are criticized. Coöperation between the producer and user in their research and development is urged. WLC (12h)

Sheet and Strip Steel for Difficult Stampings. Edw. S. Lawrence. *Metal Stampings,* Vol. 4, Oct. 1931, pages 811-812, 832.
Low C strip and sheet steels in wide, thin gages as used for difficult stampings and deep-drawing are discussed. The setting of presses, distances between punch and die are considered. Instead of the present general chemical and physical specifications, the author believes that properties for operation in such presses should be specified. Ha (12h)

Pickling (12i)

New Pickling Method Gives Thorough Scale Removal. *Steel,* Vol. 88, Mar. 12, 1931, page 51.
The Hanson-Munning bright-dip method uses 2 tanks, one containing an acid solution kept at from 120° to 150° F. Electrodes in this tank supply a current to the piece of 100 amp./ft.^{2} of surface to be cleaned at 6 volts. The second tank contains another acid solution at a slightly lower temperature than the first one, and here the current flows from the piece to the electrodes at 150 amp./ft.^{2}. The electrodes are of an insoluble lead composition. Light scale is removed in less than 5 minutes, forgings with resistant scales in 5 to 10 min. The exact procedure with subsequent rinsing is described. Ha (12i)

Pickling and Burnishing (Beizen und Brennen). H. Kurrein. *Chemikerzeitung,* Vol. 55, Feb. 18, 1931, pages 133-134; Feb. 25, 1931, pages 150-151.
The chemical principles of pickling and burnishing are explained and the various reagents for different metals are described. The practical applications are discussed. Electrochemical pickling, with or without exterior current source, anodically or cathodically, is recommended for special purposes. Pickling can be combined conveniently with degreasing. Ha (12i)

Pickling for Plating. C. M. Hoff. *Iron and Steel of Canada,* Vol. 14, Sept. 1931, pages 144-146, 153.
An article in which the purpose of pickling is briefly discussed and attention then directed to the acids normally used in pickling and the characteristics of each. Space is devoted to a discussion of the chemistry of pickling and to new developments in this field. The question of acid embrittlement is dealt with briefly, and the value of inhibitors in preventing embrittlement is pointed out. OWE (12i)

The Pickling and Cleaning of Metals. Some Considerations of the Chemical Reactions Involved. David Brownlie. *Sheet Metal Industries,* Vol. 4, Jan. 1931, pages 768-770; Feb. 1931, pages 862-864; Mar. 1931, pages 938-940.
Part V. The use of nitre cake in a 25% hot solution resulting in 6-8% free sulphuric acid is discussed but is considered as not being a paying proposition when calculated against sulphuric acid. Cleaning by the use of alkalies and alkaline salts is treated. Part VI. Discussion of tank linings and the development of mechanical aids in the pickling of metals. The use of rubber compounds as linings is lauded. Part VII. The development of submerged combustion methods is discussed. The advantages suggested in the application, cheapness of equipment, high rate of heat transmission and continuous circulation and mixing of the pickling liquor coupled with a strong "scrubbing" action. AWM (12i)

Cleaning Before Pickling. Wallace G. Imhoff. *Iron and Steel of Canada,* Vol. 14, Oct. 1931, pages 158-159, 165.
The author discusses very completely the various methods that may be adopted for cleaning articles before pickling. The advantages of tumbling are discussed in some detail, and the value of mechanical washing machines for cleaning off oil and grease is referred to. The need for careful study before a decision is made in regard to the installation of any cleaning equipment is emphasized. OWE (12i)

Cold Working (12j)

The Manufacture of Cold Drawn Steel. Earl D. Townsend. *Rolling Mill Journal,* Vol. 5, Mar. 1931, pages 195-200, 204.
The first cold drawn steel products were wire musical strings, bicycle wheel spokes, etc., manufactured in Germany. Later cold drawn steel wire was manufactured in Beaver Falls, Pa. The early workers used solid dies. The first sectional die, the forerunner of our present-day dies for cold drawing everything except rounds, was designed by Stephen Moltrup. There are 2 types of draw benches for holding the die and cold drawing the metal. The most widely used type, the chain bench, employs a chain and sprocket for transmitting the drawing power while the rack bench uses a rack and pinion mechanism. Bars are usually drawn through dies at a speed of 20-50 ft./min. for large bars and 60-120 ft./min. for small bars. The drawn bars average 40 ft. in length. Dies are made of hardened C steels, alloy steels, carboloy, etc. For drill rod and hard round wire, black diamonds or other precious stones are used. Cold drawn steel bars are used for bolts, nuts, screws, spindles, shafting, etc. Coiled wire is drawn in a wire block, which differs from a draw bench in having a winding drum instead of a carriage. Seamless material is used for drawing finished pipe or tubes. The draw bench employed is equipped with a mandrel and an adjustable rod holder. Cold drawn seamless steel tubing is used for hypodermic needles, piston cylinders, trolley poles, cream separator barrels, roller bearing races and automotive parts. The tubing produced may be round, square, hexagonal, flat, half-round, etc. Some new products made of cold drawn seamless steel tubing are airplane struts and poles for carrying electric wires. JN (12j)

The Interpretation of the Texture of Cold-Deformed Metals (Zur Deutung der Textur kaltverformter Metalle). W. E. Schmidt. *Zeitschrift für technische Physik,* Vol. 12, Nov. 1931, pages 552-555.
The interpretation hypothesis on the texture of cold deformed metals developed by W. Boas and E. Schmidt is critically discussed and the assumptions made by F. Weber and W. E. Schmidt are emphasized. EF (12j)

Strip Tempers Modified by Rolling after Annealing. Jos. S. Adelson. *Steel,* Vol. 88, Mar. 5, 1931, pages 50-53; Mar. 19, 1931, pages 40-46.
The process of manufacturing cold strip, the different temper ranges and the types of testing machines are described in a general manner; physical characteristics and tests results are tabulated. Ha (12j)

The Cold Roll Forming of Rust-Resistant Metals. D. A. Johnston. *Metal Stampings,* Vol. 4, Oct. 1931, pages 815-816.
Typical applications of different sections cold-roll-formed from Cu, Al, Al alloys and rust-resisting steels are described and illustrated. Ha (12j)

Cleaning (12k)

Degreasing in the Chrome-Galvano-Technique. (Die Entfettung in der Chrom-Galvanotechnik.) Richard Justh. *Oberflächentechnik*, Vol. 9, Jan. 5, 1932, pages 3-4.

The importance of absolutely grease-free surfaces for electroplating or coloring of metals is pointed out, and the defects resulting from a lack of this precaution and the means to obtain a proper surface are discussed. Ha (12k)

Equipment for the Cleaning of Metal. R. W. Mitchell. *Metal Cleaning & Finishing*, Vol. 3, Jan. 1931, pages 13-26; Feb. 1931, pages 107-115; Mar. 1931, pages 195-204; Apr. 1931, pages 287-294.

These articles constitute a comprehensive review, with illustrations of plants and equipment, of advantages and applications of wood, steel and iron tanks, lead and rubber lined tanks and vitreous enameled iron and steel tanks for cleaning and pickling solutions, of stone ware, concrete, acid-proof brick, monel metal and aluminum tanks. Tank location, drainage systems, siphons, overflow dams, ventilators, tank covers and general points to be observed in cleaning plants are discussed. Ha (12k)

Faulty Cleaning of Steel Determines Failures in Enamel Finishes. *Steel*, Vol. 89, Oct. 12, 1931, page 36.

In order to preclude the possibility of the development of local or general rust under the enamel, it is important to remove any trace of alkali which was used in cleaning. Ha (12k)

Newer Methods for Cleaning Oily Metal Parts in Industrial and Technical Processes (Neuere Verfahren zur Reinigung fettiger Metallteile in industriellen und gewerblichen Betrieben). Hermann Stadlinger. *Chemiker Zeitschrift*, Vol. 54, May 7, 1930, pages 354-355.

Various methods are briefly described. A new cleaner, "P33", sold in powder form by Henkel & Co., consists of a mixture of low alkali water glass and sodium phosphate. While not strong enough to injure the skin of workmen, a boiling 5% solution readily removes oil and dirt from metal. More time is required to remove some easily saponified oils than mineral oil. Hence, its action is to emulsify rather than to saponify. Experiments show that it will not corrode Al, Zn, etc. There is also a special grade which does not attack tin-plate, brass or duralumin. By the use of special metal-washing machines, 1-4% solutions at 80° to 90° C. will serve, depending on the kind of oil and dirt. There is no fire or health hazard. See also "Recent Methods for the Cleaning of Greasy Metal Parts in Industrial Operations," *Metals & Alloys*, Vol. 2, Nov. 1931, page 272. (12k)

Polishing & Grinding (12l)

Causes of Cracks in Hardened Steel. C. E. Sweetser. *Abrasive Industry*, Vol. 12, Sept. 1931, pages 21-24; *Steel*, Vol. 89, Sept. 24, 1931, pages 31-34.

Occurrence of cracks in the ground surfaces of hardened steels under seemingly normal conditions of manufacture is caused either by heat treatment or by grinding. The real problem is to distinguish between these 2 causes. The results of a test are reported and discussed. A comparatively severe degree of grinding abuse is required to crack steel which has been properly heat treated. On the other hand, steels which have been subjected to extremely severe heat treatment may be cracked with little, if any, abuse by grinding. Cracks may be identified with their causes by observing their size, form, number and location after etching. Those which are few in number and comparatively wide and deep point to abuse in the heat treating process as the predominating cause. Cracks which occur in the form of a fine surface network indicate incorrect heat treatment and decidedly abusive grinding. Ha+WAT (12l)

Grinding Lithograph Plates. *Abrasive Industry*, Vol. 12, Oct. 1931, page 19.

The abrasive used is fine-grit silicon carbide although emery and silica sand are used in some instances. Abrasive action is brought about by steel balls ⅜ to ½ in. in diameter. With the plate in position, the abrasive grain and the balls are placed on it and enough water is added to "float" the abrasive. The bed is set in motion and as it oscillates, the inertia of the comparatively heavy balls brings about an abrasive action which imparts the correct mat surface for lithographic printing. The size of abrasive used determines the texture of the surface. Either coarse-grained or fine-grained surfaces can be produced, depending on the size of grain employed. The abrasive is replaced every 20 or 30 min. If the abrasive were used continually it eventually would be ground into a fine sludge by its own action and thus produce a mat surface too fine for practical purposes. WAT (12l)

Wheels for Smooth Finish, Carborundum Co. *Abrasive Industry*, Vol. 12, Sept. 1931, page 28.

Solid grinding wheels capable of producing extremely high finishes formerly attainable only by lapping with compound or other loose-grain agencies are being made. To develop such a grinding wheel, it was first necessary to produce uniform grain or grits of the finest sizes. Both aluminum oxides and silicon carbide are used in making these wheels, depending upon the character of the material to be finished. These powders are said to be as perfectly uniform in individual grit size as science and skill can make them. Grinding machine manufacturers have perfected their machines practically to eliminate vibration. The finishes required must be the result of a progression, a building up of comparably finer finishes with a series of progressively finer wheels and a consequent diminishing stock removal to prepare the surface for the final finish. The new type of wheels are not expected to go production grinding in the sense of the removal of large amounts of metal. WAT (12l)

Stresses and Cracks in Hardened and Ground Steel. G. R. Brophy. *Metal Stampings*, Vol. 3, Oct. 1930, pages 933-934.

Abstract of paper read before the American Society for Steel Treating, Sept. 22-26, 1930. See *Metals & Alloys*, Vol. 3, Jan. 1932, page MA 21. MS (12l)

Centerless Grinding of Bars and Tubes. (Das mittelpunktlose Schleifen von Stangen und Rohren.) W. Loewe. *Stahl und Eisen*, Vol. 51, Dec. 31, 1931, pages 1616-1618.

A centerless grinding machine is described and its advantages are discussed. After dealing with capacity and efficiency of the new machine the technical suppositions for economically grinding bars and tubes are discussed. It is pointed out that centerless grinding proves superior to any other grinding method for grinding rust and heat resisting steels. Data are given on the tolerances of the above method. GN (12l)

Polishing Aluminum. W. E. Warner. *Canadian Machinery*, Vol. 42, Oct. 15, 1931, page 32.

Aluminum can be successfully polished to a high finish provided certain precautions are taken. Owing to the softness of the metal as compared with other metals the polishing wheels used should be softer. The abrasive must be finer and have a gentler cutting action. The wheel speed must also be lower. Owing to its high coefficient of friction, the metal has a tendency to heat, which will result in the polishing wheel burning. This is only prevented by keeping the wheel speed low and by using plenty of lubricant. The first operation should be done on a canvas or rag wheel, using No. 60 to No. 100 emery as the abrasive. The wheel speed should not be greater than 6,000 ft./min. WAT (12l)

Grinding, Lapping, or Running-in Cog Wheels? (Schleifen, Lappen oder Einlaufen von Zahnrädern?) Robert Hofmann. *Maschinenbau*, Vol. 10, Mar. 5, 1931, pages 174-177.

Based on operating practices and current investigations, cog wheels produced and treated by a variety of methods are compared. Conclusions and recommendations for practice are drawn from the results. MAB (12l)

Finishing Gears. Rob. Hofmann. *Automobile Engineer*, Vol. 21, Aug. 1931, pages 305-307.

Grinding, burnishing and lapping as final operations for parts of extreme accuracy are discussed and particular reference is made to involute gears. Curves taken with the Maag center distance and concentricity apparatus illustrate inaccuracies and profiles of correctly ground gears are shown. (12l)

Coloring (12m)

Coloring of Cadmium Coatings. (Färbung von Kadmiumniederschlägen.) H. Krause. *Zeitschrift für Metallkunde*, Vol. 23, Oct. 1931, pages 283-285.

A deep black, tight deposit can be produced on Cd plating by immersion in a solution of $KClO_3 + Cu(NO_3)_2$. A brown deposit may be obtained by $KMnO_4$. Corrosion tests in 20% NaCl solution in water showed the brown deposit not to affect the corrosion resistance of the plating, but the black deposit noticeably to reduce it. RFM (12m)

Molybdenum in Coloring of Metals. (Das Molybdän in der Metallfärbung.) Geo. Buchner. *Oberflächentechnik*, Vol. 9, Jan. 19, 1932, page 14.

A few methods, mostly patented, are described by which metals can be given a surface coloring of yellow, orange, blue, black, by dipping the articles in pure Mo solutions of ammonium alone or with additions of oxalic salts, fluorides, tungstic acid and others. The Mo solutions are used in a strength of ½ to 1%; the article is made the cathode in the solution. Ha (12m)

Sand Blasting (12n)

Circulating Dust Removal and Cleaning of Dusty Air for Sandblast Blowers. (Kreislaufentstaubung und Staubluftreinigung bei Sandstrahlgebläsen.) U. Lohse. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Dec. 4, 1931, pages 913-915.

The removal of the sandblast dust is necessary not only for sanitary reasons but also because the operator can do better work in a clean atmosphere. Proper arrangement of pure air supply, illumination, general arrangement of the blast house is discussed and illustrated by a few plants. Ha (12n)

Silicosos and Foundry Sand Blasting. *Metal Industry*, London, Vol. 39, July 24, 1931, page 84.

A special flint grit abrasive of non-crystalline character is reported as being dustless and so prevents sickness losses due to Silicosis. PRK (12n)

Modern Applications of Sand-Blast Plant. T. Fearnley Allen. *Foundry Trade Journal*, Vol. 45, Dec. 17, 1931, pages 382-384.

Description of the various types of sand-blast plant now in use. Consideration is given to the consumption of air in the ordinary cleaning of gray iron castings, and attention is directed to the high pressures required for the preparation of castings for vitreous enamelling. Reference is made to the more satisfactory types of exhaust systems and to the various abrasives that have come into use in this connection. Attention is directed to the fact that to a great extent steel has replaced sand due largely to the Silicosis Regulations of the British Home Office authorities. The various applications of sand-blasting are discussed in some detail, and the use of the sand blast as a means for testing stone, wood, or composition for street paving or flooring is referred to. The article is accompanied by 3 photographs. OWE (12n)

Spinning (12p)

Improved Procedure is Outlined for Spinning Chrome-Nickel Steel. J. R. Morris. *Steel*, Vol. 89, Sept. 17, 1931, page 33.

An 18-8 alloy is used for spinning, it requires less annealing than any other stainless steel. Annealing, when required, should be done at 2000° to 2050° F. Tools are preferably of a Ni-Cr cast-iron with 3% C, 2.5 to 3% Ni, 0.75 to 1% Cr and 1.2 to 1.5% Si. Water soluble lubricants are recommended. Ha (12p)

Spinning Covers a Special Machine. F. C. Hudson. *American Machinist*, Vol. 75, Sept. 3, 1931, page 386.

Detailed description of a semi-automatic spinning machine, built-up by welding. Ha (12p)

DEFECTS (13)

Searching for Flaws in Rails. *Railway Age,* Vol. 92, Jan. 30, 1932, pages 194-196.

After years of study and close coöperation with the late E. A. Sperry, in the development of the transverse fissure detector, the New York Central Railroad has placed in operation a detector car of its own, which incorporates the latest features in the art of rail flaw discovery. This new car differs in very many respects from anything of its kind ever built. It meets all the requirements of the signal department, contains its own motive power, weighs 150,000 lbs. and is equipped with automatic train control. The range of speed varies from 5-55 miles per hour. It contains complete living quarters as well as certain equipment maintenance facilities. The record compartment is approximately 19 ft. long. Complete details of how defects are detected are presented. When a defective rail is found it is given a serial number and a record is made of its exact location as well as the name of the manufacturer, date rolled, heat number, etc. These rails are replaced immediately by tested rails. WAT (13)

New Method for the Detection and Recording of Rivet Hole Cracks. (Neue Methode zur Auffindung und Darstellung von Nietlochrissen.) H. Stehr. *Die Wärme,* Vol. 53, Sept. 27, 1930, pages 730-731.

The occurrence and detection of cracks around rivet holes is discussed and the author outlines his newly invented method of determination. A sulphide solution is brought upon the surface to be tested. Due to the capillary effect, part of the solution is sucked even into the smallest crevices while the rest is being removed from the surface. Next a silver bromide paper soaked in H_2SO_4 is pressed against the metal sheet. Black silver sulphide is formed at the cracks thus yielding a true copy of the defects, which can be evaluated quantitatively. EF (13)

Investigation into the Cause of a Crack Formation between the drilled Tube Holes of a Vertical Tube Boiler. (Ermittlung der Ursachen eines Risses zwischen den Bohrlöchern eines Steilrohrkessels.) Schuhmacher. *Die Wärme,* Vol. 54, Sept. 12, 1931, pages 689-693.

The micro-structural examination disclosed an improper heat treatment of the boiler material resulting in a failure due to aging. EF (13)

The Influence of Impurities in Foundry Brasses and Bronzes. H. M. St. John (Detroit Lubricator Co.). *Metals & Alloys,* Vol. 2, Oct. 1931, pages 242-245.

31 references. The author has summarized the literature on the subject of impurities in brass and bronze foundry alloys. Impurities are classified as gases, metallic and non-metallic impurities. These classes are discussed as such and then specific elements, gases and non-metallics are discussed individually. WLC (13)

Investigation of the Failure of a Copper Fire-Box (Untersuchung über Rissbildung bei kupferenen Feuerbüchsen). O. Schroeder. *Glasers Annalen,* Vol. 55, July 1, 1931, pages 6-8.

A chemical and metallographic investigation on a fire box, which developed cracks during the repair work by welding, disclosed the presence of copper oxide as the cause of the failure. EF (13)

Scabs in Castings Traced to Molding Sand Defects. *Steel,* Vol. 88, June 18, 1931, page 53.

Brief review on several papers on this subject of a French Convention. Ha (13)

Distribution of Oxide and Sulphide Inclusions in Steel. Correspondence from W. Zieler, Düsseldorf, Germany. *Metal Progress,* Vol. 21, Feb. 1932, pages 68-69.

The writer discusses the difference in the locations of oxide and sulphide inclusions in steel ingots. WLC (13)

Grain-Growth in a Turbine Wheel Heated by Friction. *Engineering,* Vol. 131, June 12, 1931, page 752.

Failure of a steam turbine was caused by the deformation of a cast-iron diaphragm which touched the adjacent wheel which raised the temperature causing recrystallization of the steel. Photomicrographs are given showing the granular structure of the steel. LFM (13)

Failures of Rails. (Schienenbrüche bei ausländischen Eisenbahnverwaltungen.) W. Marzahn. *Stahl und Eisen,* Vol. 51, Nov. 5, 1931, pages 1377-1379.

The article gives a résumé of the results of questionnaires compiled by various railroad administrations. (See Cambournac & Patte, *Bulletin de l'Association Internationale du Congres des Chemins de Fer,* Vol. 11, 1929, pages 923-1024.) The failures due to segregations, the so-called nodular fractures, longitudinal fissures in the flange and faults of the surface are discussed. The results of a comprehensive investigation on nodular fractures by S. Ikeda published in *Bulletin de l'Association du Congres Internationale des Chemins de Fer,* Vol. 11, 1929, pages 2506-2518 and carried on by the Research Department of the Japanese Government Railway are given. Ikeda is of the opinion that this transverse fracture is some kind of a fatigue which starts in the interior of the rail. The reviewer states that the origin of the nodular fractures is stresses which are developed on the hot bed or during straightening the rails. Longitudinal fissures were frequently observed during the extremely cold winter of 1929 in France, Germany, Sweden and other countries. These failures are actually due to extreme cold. An investigation of the corrosion of rails has also been carried out by the Research Department of the Japanese Railway as reported by E. Matsunawa in *Bulletin de l'Association Internationale du Congres des Chemins de Fer,* Vol. 11, 1929, pages 1329-1349. This author found that sea air corrodes as well as the ash of the Japanese oils used for driving the engines. Corrosions of rails in tunnels is due to the increased content of SO_2 in the air. Remedies suggested are to drop water containing Na_2CO_3 upon the rails in order to neutralize the acid; to suck the combustion gases out of the tunnel by means of an exhaustor; and to use rails containing copper. GN (13)

CHEMICAL ANALYSIS (14)

The Analysis of Coating of Galvanized Sheet Steel. (Fe, Pb, Cd, Sn and Zn). Frank W. Scott. *Chemist-Analyst,* Vol. 20, Mar. 1931, pages 4-5.

Three samples, 2¼" square, are cleaned, dried and weighed and placed in a 400 cc. beaker, their bottom edges resting on c.p. Zn. The samples are covered with 1:10 H_2SO_4 until the action ceases, about 10 min., when the acid is replaced with H_2O. The samples are scrubbed with a policeman, dried and weighed. Fe in the solution is reduced and titrated with $KMnO_4$. HNO_3 and H_2SO_4 are added to the solution and it is evaporated to fumes, adding crystals of $(NH_4)_2SO_4$. After diluting, $PbSO_4$ is filtered and weighed on an asbestos mat. The filtrate is heated to boiling and H_2S passed through. NH_4OH is added until CdS and a little ZnS precipitates. After filtering, the sulphides are dissolved in 100 cc. 1:9 HCl, neutralized with NH_4OH, 6 cc. HCl is added and H_2S again passed through. A few drops of NH_4OH are added to start precipitation if necessary. The sulphides are filtered, dissolved in 1:1 H_2SO_4 and CdS is reprecipitated with H_2S after adding 5 g. NH_4Cl and diluting to 400 cc. CdS is filtered and weighed on a Gooch crucible. For the Sn determination three more samples are stripped using 1:5 HCl. H_2S is passed through the solution and it is half neutralized with NH_4OH and diluted to 450 cc., continuing the H_2S treatment. The sulphides are filtered with the aid of paper pulp and dissolved in 10 parts 1:1 HCl and 1 part HNO_3. After boiling and diluting to 200 cc. the solution is almost neutralized with NH_4OH, using methyl orange. An excess of ammonium acetate is added and the solution is allowed to stand in a warm place until gelatinous $Sn(OH)_2$ separates. It is filtered, using paper pulp, ignited and weighed as SnO_2. Zn is taken by difference. CEM (14)

Chemical Analysis of Iron and Steel. G. E. F. Lundell, James Irvin Hoffman & H. A. Bright. John Wiley & Sons, Inc., New York, 1931. Cloth, 6 x 9 inches, 641 pages. Price $7.00.

Chemists who have used the excellent treatise "Applied Inorganic Analysis," by Dr. Hillebrand and Dr. Lundell, will welcome this new book. Since it covers a much narrower field than the former book, it gives details of manipulation more minutely. The same meticulous care has been exercised in its preparation and the book is replete with references.

The work is divided into 5 parts. The first, under the title "General Considerations," deals with apparatus and reagents; qualitative tests of steels; separation of iron from accompanying elements; common operations, such as sampling, weighing, choice of method of analysis, solution of the sample, precipitation, filtration, washing, drying and igniting precipitates, and the determination of blanks; special operations, including the removal of ammonium salts and organic matter from solution; volumetric analysis, including an excellent discussion of the use of indicators and a simple though thorough outline of potentiometric titrations; accuracy of determinations; and standard samples. Part 2 (260 pages) considers methods for the determination of the constituents of irons and steels. The elements are divided into 3 groups: (a) Ordinary constituents: Fe, C, Mn, P, S, Si; (b) common alloying constituents: Cu, Ni, Cr, V, Mo, W and Co; and (c) less common constituents: Al, Ti, Zr, Cb and Ta, U and the rare earths, arsenic, tin and antimony, zinc and boron. Usually a chapter, averaging about 13 pages, is devoted to each element. Part 3 deals with methods for the determination of oxygen, oxide inclusions, hydrogen, and nitrogen. Part 4 takes up the analysis of ferro-alloys, and part 5, methods for the analysis of ores, limestones, fluorspar, refractories, slag, molding sand, and coal and coke.

The authors state (page 129): "A distinction should be drawn between accuracy and precision. Briefly, but somewhat roughly stated, accuracy is a measure of degree of correctness; precision is a measure of reproducibility in the hands of a given operator. The precision of a result does not have anything to do with its accuracy. It merely serves as a measure of the duplicability of the procedure in the hands of a given operator." With this as their thesis the authors outline procedures leading not only to reproducible results, but also giving the degree of accuracy demanded for a given type of determination.

The determination of each element is discussed in much the same manner. Under general considerations, the method by which the element finds its way into iron or steel, its effect, and the usual amounts found in various kinds of iron and steel are discussed. Methods of decomposition, separation and determination are taken up in order. Routine and empiric determinations are considered. Precautions to follow and the effect of interfering elements are outlined. In many instances more than one method of analysis is described.

At the end of each chapter, a table gives the accuracy of determinations of the element. This includes the Bureau of Standards sample number, material (i.e. Bessemer 0.1 carbon steel, A.O.H. 0.6 carbon steel, etc.), probable value, extreme results, average deviation from probable value, results outside of average deviation of all results, number of results reported, number reported high and number reported low.

Chemists usually search in vain in books on the analysis of iron and steel for the determination of small quantities of such contaminating elements as Cr, Mo, and V found in plain carbon steels. In this book the authors describe special colorimetric methods for such determinations.

There are remarkably few typographical errors or omissions, although on page 384, in discussing the analysis of tin, one is instructed to "add a solution of about 10 or 20 ml. of antimony chloride of sulphate.

The book appears to have been prepared with great care. Accuracy such as has been attained at the Bureau of Standards can be secured only by strict adherence to the minutest details of manipulation and procedure. The authors have furnished an invaluable tool to analytical chemists. J. D. Sullivan. (14)-B-

HISTORICAL & BIOGRAPHICAL (15)

The Advances of Steel Making in Electric Furnaces (Le développement mondial de la production d'acier au four électrique). *Journal du Four Electrique,* Vol. 40, Dec. 1931, pages 470-471.

A short summary of the development of electric furnace steel making in the world from its conception to the present time. JDG (15)

Pig Iron in Canada. George A. Simpson. *Canadian Foundryman,* Vol. 22, Oct. 1931, page 19.

A very brief résumé of the history of the pig iron industry in Canada from 1800 to 1853. OWE (15)

Permanent International Commission for Acetylene Autogenous Metal Working and Affiliated Industries. (Ständige Internationale Commission für Azetylen, autogene Metallbearbeitung und verwandte Industrieen.) *Die Schmelzschweissung,* Vol. 11, Jan. 1932, pages 12-13.

The history of the commission, countries participating, meetings held are reviewed. World consumption of calcium carbide, oxygen and liquid acetylene is tabulated. Ha (15)

Founding Throughout the Ages. *Foundry Trade Journal,* Vol. 45, Oct. 15, 1931, page 244.

Report of an address on the above subject by G. C. Castle. Reference is made to some of the more outstanding examples of the foundryman's art, which have been brought to light by archaeologists and of which information is at hand today. OWE (15)

Incredible Carnegie. J. K. Winkler. Vanguard Press, New York, 1931. Cloth, 6 x 9½ inches, 307 pages. Price $3.50.

This account of Carnegie's career is written in the modern biographical style, featuring the shortcomings of the man described. Carnegie is characterized as cold-blooded, making his fortune by using men ruthlessly. He was not interested in technical details; his forte was in choosing and handling men. Up to the time he sold out at 66, he is shown as a hard and ruthless man. The remainder of his life was devoted to philanthropic work, but, according to Winkler, his philanthropy was rooted in a desire for adulation rather than in a sincere desire to help mankind. A twelfth of the income of the U. S. Steel Corporation is still said to be "clutched from the grave" by Carnegie for the support of his various foundations.

The biography may show all facets of Carnegie's nature in their proper light, but one wonders if, after all, a truly fair biographer would not have found something in his character to admire. A man who spent his last day of health bass-fishing might have been dealt with more generously. Winkler writes with the assumption of impartiality but does not convince the reader that he is impartial. The book seems to be written by a biographer rather than an historian.

The book is about Carnegie, not about the steel industry, but side comments on the revolutionary advances in technology and production methods made by his associates will interest the metallurgist. H. W. Gillett (15)-B-

The Black Country and Cold Blast Pig Iron. *Iron & Steel Industry & British Foundryman,* Vol. 5, Dec. 1931, pages 80-82.

A short history of the development of the industry in the Black Country, South Staffordshire. This iron has the property of throwing a chill with absolute certainty. The lower the Si and the higher the S, the deeper the chill, as a rule. CHL (15)

Activities of the Verein deutscher Eisenhüttenleute for Year 1931. (Ueber die Tätigkeit des Vereins deutscher Eisenhüttenleute im Jahre 1931.) *Stahl und Eisen,* Vol. 52, Jan. 21, 1932, pages 53-68.

Number of papers published on various subjects given for 1931 and total since year 1840. Important papers and work of committees are discussed with relation to industry, such as Siemens-Martin and Thomas Steel processes, electrolytic steel, rolling mill, coke and gas plant, annealing, heat treatment, etc., and also work done jointly with other organizations. DTR (15)

A Review of Water Works Progress. Caleb Mills Saville. *Water Works Engineering,* Vol. 85, Jan. 27, 1932, pages 85-88.

The development of water works engineering as a science during the past half century period. Introduction of various features such as cast iron pipe, new types of pumping machinery, wrought iron, steel, and concrete pipe, meters, etc., are touched upon from a historical as well as scientific standpoint. CBJ (15)

Wrecking Home Insurance Building Reveals Excellence of Old Metals. Henry Penn. *Engineering News-Record,* Vol. 108, Feb. 18, 1932, pages 247-248.

Building dismantled in Chicago was built of cast Fe, wrought Fe and the first steel beams used in a building in this country. Chemical analyses, photomicrographs, and physical tests of the metals used are included. CBJ (15)

Development of the German Steel Industry in the Last 50 Years. (Entwicklungslinien des deutschen Eisenhüttenwesens in den letzten 50 Jahren.) O. Petersen. *Stahl und Eisen,* Vol. 52, Jan. 7, 1932, pages 1-13.

Paper before the 123rd Annual Meeting of the Verein deutscher Eisenhüttenleute, Nov. 29, 1931, Düsseldorf. A most interesting, detailed and illustrated description of the progress of the German steel industry in the last 50 years. GN (15)

The Reduction of the Corrosion Tendency of Steel. (Die Verminderung der Korrosionsfähigkeit des Stahls.) Sedlaczek. *Korrosion,* Beilage zur *Chemischen Apparatur,* Vol. 6, Nov. 25, 1931, pages 49-50.

A historical compilation of patents on the production of rustless or corrosion proof steels. The earliest example is a suggestion by Berthier in 1821 who recommended an addition of Cr. Ha (15)

Rails 1831-1931, A Century of Development. T. J. Stillman (Penna. R. R.) *Metal Progress,* Vol. 20, Nov. 1931, pages 37-42.

The author recounts the development of the all metal rail of T-shape from 1831 to the present. The change from iron to steel and from a weight of 36 lb./yard to 152 lb./yard; these latter rails are now the standard on the heavy traffic sections of the Pennsylvania Railroad. Specifications and steel quality are reviewed. WLC (15)

ECONOMIC (16)

The Non-Ferrous Metals in 1931. *Foundry Trade Journal,* Vol. 46, Jan. 14, 1932, pages 30, 32.

An article in which special attention is directed to the world market for copper during 1931. OWE (16)

The Demand for Cast Iron—Past and Present. *Foundry Trade Journal,* Vol. 45, Oct. 8, 1931, page 224.

Reviews the manner in which competition has lessened the market for iron foundry products. He emphasizes the value of national advertising schemes in promoting interest in various materials and shows by reference to a number of different products, which can be made in cast iron, what might be looked for in the way of new business if efforts were made to obtain it in the manner described above. OWE (16)

The Foundry Equipment Industry in 1931. D. Howard Wood. *Foundry Trade Journal,* Vol. 46, Jan. 14, 1932, page 36.

A brief statement of changes which have occurred in 1931 in the equipment of foundries in Great Britain. Some reference is made to mechanization which has taken place in certain foundries in the U. S. A. and to the fact that some of these improvements have been adopted in Europe. OWE (16)

Engineering Achievements of Industry Rank High in Depressed 1930. E. F. Ross. *Steel,* Vol. 88, Jan. 1, 1931, pages 279, 290.

Although a period of greatly restricted production, the year 1930 witnessed considerable engineering and technical progress, with many improvements in production methods and a noteworthy expansion in research and scientific work. JN (16)

Reduction of Costs and Improved Quality by New Shop Methods of Measurement. (Kostensenkung und Gütesteigerung durch neuzeitliche Werkstattmessverfahren.) O. Schlippe. *Maschinenbau,* Vol. 10, Feb. 19, 1931, pages 134-139.

The demand for change is being forced to standardization. Systematic building up of the whole method of measurement is being attempted by workmen and technical societies. This standardization is indicated in the literature in several places. The development of measuring methods and the tests of the methods, have led to increased accuracy in testing and to improvements in apparatus. Several examples are cited. MAB (16)

The Effect of Business Demands on the Economy of Power and Materials in Plant Operations. (Der Einfluss des Beschäftigungsgrades auf die Energie-und Stoffwirtschaft der Hüttenwerksbetriebe.) Berthold von Sothen (Düsseldorf). *Stahl und Eisen,* Vol. 52, Jan. 14, 1932, pages 29-38; Jan. 21, 1932, pages 68-70.

Includes 16 references, 5 tables, and 18 diagrams. With mill demands cut from 30 to 40%, study of production methods was made in modern blast furnace—mill—steel—gas—coke plants from angle of cost, in order to arrive at most economical number of working days per week. Heat and power requirements and efficiency of furnaces and machines are emphasized. Daily costs of producing gas from coke in the intermittent and continuous producers are given. The trend is towards use of cheaper coals, such as Saar peat and smudge, and intermittent use of outside gas and electricity. GN + DTR (16)

Electrified Trackage Becoming more Concentrated. *Transit Journal,* Vol. 76, Jan. 1932, pages 19-21.

Total trackage operated has decreased 14.9% since 1923. Abandonments have been confined to small cities and communities. CBJ (16)

World's Production and Consumption of Lead in 1930. (Produccion Y Consumo De Plomo En El Mundo En 1930.) *Revista Minera,* No. 3288, Nov. 1931, pages 517-18.

Reprinted from *Metallgesellschaft,* 1931. In thousands of metric tons, world production for 1920, 1925 to 1930 inclusive: 859, 1,485, 1,565, 1,638, 1,598, 1,662, 1,560, respectively. Total consumption: 975, 1,497, 1,560, 1,602, 1,640, 1,689, 1,505. DTR (16)

World's Production and Consumption of Zinc. (Produccion Y Consumo De Zinc En El Mundo.) *Revista Minera,* No. 3291, Dec. 1931, pages 557-58.

World's consumption 1920, 1925 to 1930 inclusive, in thousands of tons: 688, 1,176, 1,228, 1,308, 1,412, 1,435, 1,223, respectively. Production for same years: 735, 1,166, 1,380, 1,392, 1,379, 1,499, 1,312. DTR (16)

International Tin Research. *Tin,* Dec. 1931, pages 1-2.

The British Tin Producers have subscribed a sum of £28,000 a year for research and development work in expanding the existing market for Sn, to find new markets, and to preserve and strengthen those markets where Sn meets with rivals. A particular problem to be treated is Sn plate. Ha (16)

The Need of a Copper Tariff. A. E. Petermann. *Mining and Metallurgical Society of America, Bulletin* No. 222, Vol. 24, Dec. 1931, pages 84-94.

The need of a tariff on Cu is discussed from the points of view of national economy and national defense. Ha (16)

Copper Tariff. Arthur Notmann. *Mining and Metallurgical Society of America, Bulletin* No. 222, Vol. 24, Dec. 1931, pages 102-115.

The pros and cons of a high tariff are weighed against one another; it is concluded no tariff is necessary. We could buy up for the navy and army, all cheaply offered Cu in the market for a war stock. Ha (16)

The Foundry Industry in Czecho-Slovakia in the Year 1931. Frant. Pisek. *Foundry Trade Journal,* Vol. 46, Jan. 14, 1932, page 26.

A brief description of the production, employment, and equipment figures for the foundry industry in Czecho-Slovakia during 1931. OWE (16)

Investigation of the Economy of a Rolling Schedule (Untersuchung der Wirtschaftlichkeit eines Walzprogramms). V. Polak. *Stahl und Eisen,* Vol. 51, Dec. 24, 1931, pages 1593-1594.

The author advises that means for calculating the costs of rolling of various shapes to be rolled by a mill be devised. GN (16)

PLANTS & LABORATORIES (17)

The "Trinec" Continuous Bar and Sheet Billet Rolling Mill. *Demag News,* Vol. 5C, Nov. 1931, pages C33-C41.

The new plant of the Berg und Huettenwerks-Gesellschaft Trinec, Czechoslovakia, is designed to roll blooms of maximum 4.5 tons, 10 in.^{2}, into sheet bars $1\frac{1}{16}$ to $1\frac{3}{8}$ in. thick and 12, 10 or 8 in. wide, and billets and sheet bars. The output is 125 tons of sheet bars per hour. Two continuous trains are installed, billet and sheet rolling schedules are diagrammatically illustrated and the whole plant with auxiliary equipment described. Ha (17)

London Headquarters of British Non-Ferrous Metals Research Association. *Engineering,* Vol. 131, June 12, 1931, pages 772-773.

Description of the equipment of and scope of the research done in the laboratories of the International Nickel Company. Ha (17)

Production Economy in Iron and Steel Works. Part I. OTTO CROMBERG. *Engineering,* Vol. 131; May 15, 1931, page 650.

Abstract of a paper read before the Iron and Steel Institute, London, May 1931. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 276. LFM (17)

Individual Roll Motors—Photo-Electric Cells—Tools of a Modern Steel Mill. RALPH H. WRIGHT. *Electric Journal,* Vol. 28, July 1931, pages 403-407.

An illustrated description of a mill in which electric requirements have been introduced to the utmost degree. WHB (17)

Modern Heat Treating Equipment Cuts Cost to One-Third for Cleveland Tractor Co. JOSEPH GESCHELIN. *Automotive Industries,* Vol. 65, July 1931, pages 46-47.

Description of Cleveland Tractor Company modernized plant. 2 pusher type furnaces both gas and electrically fired, special gas carburizing horizontal retort furnaces are shown in detail. DTR (17)

The Foundries of Messrs. Alfred Herbert, Limited. *Foundry Trade Journal,* Vol. 45, July 16, 1931, pages 40-42.

An article accompanied by 8 photographs and 1 diagram showing the general layout of the foundries referred to above. Details are given of the equipment of these foundries, which are designed for the production of castings to be used in the manufacture of machine tools. OWE (17)

The Acton Precious Metals Refining. *Canadian Mining Journal,* Vol. 52, May 15, 1931, pages 509-510; *Brass World,* Vol. 27, June 1931, pages 133-134; *Industrial Chemist,* Vol. 7, May 1931, pages 207-208; *Metal Industry,* London, Vol. 38, Apr. 24, 1931, pages 425-428.

The metallurgical equipment of this plant is described. Smelting and cupellation are carried out in small basic lined tilting furnaces of novel design, charges being poured from these oil-fired furnaces. The scrubbing plant recovers more than enough precious metals to pay for its operation. The equipment for the wet process buildings is compactly arranged on a series of terraces of acid-proof construction. The Clydach concentrate containing a relatively large proportion of Ag and Pb receives an initial smelting operation —the Pb absorbing the precious metals. Cupellation removes most of the Pb. Parting is effected with sulphuric acid. Subsequent treatment with aqua regia removes Pb, Pd, and Au. Pt is precipitated as ammonium platino chloride and Pd as palladosammine chloride. Ag and Au are purified by electrolysis. Ru, and Ir in the final insolubles and reduction residues are remelted to concentrate them and the alloy obtained is returned for wet treatment. WHB&RAW&PRK (17)

Cast Iron Pipe Competing with Steel. *Metal Progress,* Vol. 19, Apr. 1931, pages 71-74.

Describes the plant and methods for making cast iron pipe by the American Radiator Company. WLC (17)

Annealing Plant of Franz Seiffert & Company, Eberswalde, Germany (Glüheinrichtung bei der Firma Franz Seiffert & Co.) *Zeitschrift Verein deutscher Ingenieure,* Vol. 75, Jan. 24, 1931, pages 112-113.

The very high steam pressures used at present in power plants require pipes of highest quality. All cold working of the material to be used in such pipe lines must be avoided in manufacturing it, since aging phenomena which have a harmful influence on the material and reduce the operating safety are produced by cold working. Careful treatment in annealing subsequent to working is necessary. The furnaces of this company are briefly described. Ha. (17)

MACHINERY & SUPPLIES (18)

The Design and Application of Cranes to Steel Mill Service. Part II. G. W. YANNEY (The Alliance Machine Co.). *Rolling Mill Journal,* Vol. 5, Mar. 1931, pages 201-204.

Safety features on the all-electrically operated crane of today include steel footwalks around girders and beams, platforms under bridge girders and trolleys, gears completely enclosed or guarded, guarded shaft couplings, forward track wheels equipped with fenders, rope sheaves and shafts completely covered, automatic limit stop for crane hook, and safety compartment in operator's cab. Within the last 5 years, there has been a change from cast iron to cast steel as a material of construction, resulting in added safety, extended life, reduced weight, and reduced power consumption. All parts subject to repair or renewal are made readily accessible by means of walkways and platforms. Points of lubrication are easily reached. The modern crane designer strives for simplicity of design, the avoidance of a multiplicity of different parts, compactness within the bounds of accessibility, and an attractive general appearance. JN (18)

Pig Bed Crane with Separate Grabs for Pig Breaking and Loading. *Demag News,* Vol. 5C, Nov. 1931, pages C45-C47.

Describes the construction. Ha (18)

Feeder Trucks for Blast Furnace Charging Plants. *Demag News,* Vol. 5C, Nov. 1931, pages C42-C45.

The mechanical construction and operation is described. Ha (18)

Modern Stretching Machines. (Neuzeitliche Spann-und Streckmaschinen.) H. KREBS. *Stahl und Eisen,* Vol. 51, Feb. 19, 1931, pages 232-234.

The continually increasing demand for steel sheets has brought with it a demand for improved quality, in respect to physical and mechanical properties, homogeneity, uniformity of thickness, and surface. This has led to the development of new types of apparatus, for stretching and straightening sheets, and at the same time avoiding uneven straining of them. Such a machine fitted with strain control and stress distribution devices and other tensile testing machines for testing bars and strips with perfectly uniform distribution of the stress is illustrated. Ha (18)

The Degree of Rigidity of Tool Machines. (Der Starrheitsgrad von Werkzeugmaschinen.) CARL KRUG. *Maschinenbau,* Vol. 10, Aug. 6, 1931, pages 505-506.

This is an article which follows up the line of thought presented in a paper by Dr.-Ing. Reichel on the same subject, published in *Maschinenbau,* Vol. 10, Apr. 16, 1931. It presents a method of evaluating tool machines, which should be of value to German tool machine manufacturers. MAB (18)

Design and Construction of Turbo-Blowers for Steel Mills (Entwurf und Ausführung von Turbogebläsen für Hüttenwerker). M. SCHATTSCHNEIDER. *Stahl und Eisen,* Vol. 51, Nov. 5, 1931, pages 1361-1370.

Report of the Committee on Machinery of the Verein deutscher Eisenhüttenleute. The article deals with the general principles which must be borne in mind in designing turbo-blowers to meet the requirements for obtaining a high efficiency. These conditfons are illustrated in diagrams. The devices of air outlet and diffuser regulation are described and data are given on aspirated volume, air pressure, number of revolutions. The general layout of turboblower plants for a 300 ton and a 1000 ton blast furnace are diagramatically shown. Some sketches show new designs of blowers as they have been installed at the Huckingen plant of the Mannesmann Tube Works and at the Friedrich Alfred plant of the Krupp Works. The paper concludes with some information on turbo-blowers for Bessemer plants which have been built by the Brown, Boveri Company. GN (18)

Iron and Steel Plant Pumping Equipment. JOHN H. JONES. *Rolling Mill Journal,* Vol. 5, Nov. 1931, pages 727-730.

Types of pumps and factors for their efficient operation are explained. Ha (18)

Recent Developments at the International Foundry Exposition at Milan. (Neuerungen auf der Mailänder Internationalen Giesserei-Fachausstellung.) TH. GEILENKIRCHEN. *Die Giesserei,* Vol. 18, Dec. 11, 1931, pages 931-934; Dec. 25, 1931, pages 948-953.

Several new constructions, especially of Italian machinery, of recent development are described in the fields of transport equipment, molding machines, molding sand preparing machines, shaking-presses and auxiliary equipment in the foundry. Ha (18)

The Driving of Mill Table Rollers. WM. ALBRECHT. *Rolling Mill Journal,* Vol. 5, Sept. 1931, pages 611-614.

The advantages of the individual drive of mill table rollers are explained and the different types of motor-driven rollers developed for this purpose described. Ha (18)

Device for the Transportation of Billets from One Roller Bed to Another (Vorrichtung zum Befördern von Knüppeln von einem Rollgang zum anderen). P. TERPE. *Stahl und Eisen,* Vol. 51, Nov. 19, 1931, pages 1437-1438.

Description of a simple ingenious device to swing billets weighing about 400 lbs. from the runout of the billet mill over to the rolling bed of a rod mill rectangular to the billet mill. The manual labor of 2 men could thus be saved. GN (18)

Blast Furnace Blowing Engines. The Relative Merits of the Gas Engine and the Turbo-Blower. F. JOHNSTONE TAYLOR. *Iron & Steel Industry & British Foundryman,* Vol. 5, Dec. 1931, pages 109-114.

A summarization of both sides of the case. CHL (18)

Metal Baths for Carrying Heat to Cooking, Distillation and Similar Apparatus. (Metallbad zur Wärmeübertragung für Koch-, Destillier-und ähnliche Apparate.) TH. MELZ. *Apparatebau,* Vol. 43, Apr. 2, 1931, pages 76-77.

A short description of the construction of a few metal heating baths. Ha (18)

MISCELLANEOUS (20)

Use of the Correct Lubricant and Proper Protection for Bearings in Stock will Go Far toward Preventing Anti-Friction Bearing Troubles. Elmer Zitzewitz (Aetna Ball Bearing Manufacturing Co.). *Blast Furnace & Steel Plant,* Vol. 19, Nov. 1931, pages 1471-1472.

All bearings not in use and before installations should be kept in sealed wrappings so as to protect against dirt, moisture and the atmosphere, after coating them generously with a rust preventive. Oil is preferable as a lubricant for high speeds and grease for low speeds. Only a pure mineral oil or grease should be used. Loss of lubricant because of leakage and vaporization can be obviated by sealing the bearing. To eliminate most of the troubles now being experienced with anti-friction bearings, it is important to choose the proper size and type of bearing, mount it properly, lubricate it properly and maintain it properly. MS (20)

Overhead Handling in a Stamping Plant. Thorpe E. Wright. *Metal Stampings,* Vol. 4, Aug. 1931, pages 641-643.

The importance of transportation costs of the parts moved from place to place in stamping plants with regard to overhead costs is noted. Their possible reduction is illustrated by an example of a factory for automobile head lamps. Ha (20)

The Metallurgist in the Foundry. F. S. Wordsworth. *Foundry Trade Journal,* Vol. 45, Oct. 22, 1931, page 253-254.

A discussion of the status and duties of the metallurgist in the foundry and the improvement that comes through a scientific viewpoint of foundry problems. Reference is made to the valuable work which has been done by the British Cast Iron Research Association in assisting British foundrymen, and attention is directed to the need of financing further research work in foundry practice. OWE (20)

Lead Solution Used to Recover Tin from Scrap. A. E. Buchanan. *Scientific American,* Vol. 146, Feb. 1932, page 107.

A new method for reclaiming the tin plate from old tin cans has been developed. The tin plate is treated with a solution of 4.45% lead, 10.25% caustic soda and 85.3% water. At a temperature of 90° C., the tin is removed by this solution from the tin plate in a few secs. and, until the lead in the solution is nearly all displaced, the rate of attach is high. In the reaction, for every 2 atoms of tin dissolved, 3 atoms of lead are deposited. Because of the deposition of finely divided lead, it is necessary to agitate the tin plate to ensure its removal from the surface of the material. Revolving drums are so used that the process is continuous. The sodium stannate solution obtained is treated with caustic lime, by which a precipitate of calcium stannate is obtained and the caustic soda solution regenerated for use. The precipitated lead is placed in a tower with the regenerated caustic soda and air is blown through. After 20 hrs., the original treating solution is obtained by hydration of the lead and its solution in the liquid. WAT (20)

The Reactions of Active Nitrogen with Hydrogen Atoms at Metallic Surfaces (Ueber die Reaktion von aktivem Stickstoff mit Wasserstoffatomen an metallischen Oberflächen). J. K. Dixon & W. Steiner (University of Berlin). *Zeitschrift für physikalische Chemie,* Abt. B, Vol. 14, Nov. 1931, pages 407-412.

The formation of ammonia from atoms of N and H at the surfaces of Cu, Fe, Ni and Zn was investigated. The course of the reaction and its dependence on the H-atom concentration is in accordance with the authors' assumptions, previously published (see *Zeitschrift für physikalische Chemie,* Bodenstein Festband, 1931, pages 817-830) that the formation of NH_3 takes place over NH as an intermediary product in 3 phases. EF (20)

Flexibility of Plain and Creased Pipe Bends. A. M. Houser & S. Hirschberg. *Power,* Vol. 74, Oct. 20, 1931, pages 568-571.

A discussion. AHE (20)

Lubrication of Steel Mill Motors. J. L. Brown. *Rolling Mill Journal,* Vol. 5, Sept. 1931, pages 607-610, 614-615.

Different principles and systems of lubrication of electric motors are described. Ha (20)

Processes for the Preparation of Pure Carbides, Nitrides and Borides of High Melting Points and Description of some of their Properties. (Methoden zur Reindarstellung hochschmelzender Karbide, Nitride und Boride und Beschreibung einiger ihrer Eigenschaften.) C. Agte & K. Moers. *Zeitschrift anorganische und allgemeine Chemie,* Vol. 198, June 10, 1931, pages 233-275.

A few methods for the production of pure carbides, nitrides and borides are described; the purification is effected by annealing at highest temperatures. The following materials were prepared, which represent the highest melting points:

Zirconium—carbide	Zr C	Melting point	3805° C.
Hafnium—carbide	Hf C	"	4160° C.
Zirconium—nitride	Zr N	"	3255° C.
Tantalum—nitride	Ta N	"	3360° C.
Zirconium—boride		"	?265° C.
Hafnium—boride		"	3335° C.

The melting point curves of the two systems titanium carbide—titanium nitride and tantalum nitride—tantalum carbide were determined; a maximum melting point could be stated at a composition of equal mols of Ti N and Ti C. Tables of electrical conductivity with temperature coefficients are reproduced. Ha (20)

Residual Strains in Materials used in Machine Construction. (Zulässige Spannungen der im Maschinenbau verwendeten Werkstoffe.) Ernst Bock. *Maschinenbau,* Vol. 10, Feb. 5, 1931, pages 68-83.

Reviews various papers by Dr.-Ing. Bock covering the following subjects: Formation of the guide lines for structures; strength of the materials; factors of safety; scientific influences; deformation; the state of strain; recognition of fracture; reliability of tables giving "residual" strains; curves indicating the limit of strain; method to be taken as a model for construction of machine parts. MAB (20)

LABORATORY APPARATUS (21)

Electrical Resistivity of Certain Copper Alloys in the Molten State. C. S. Williams (Westinghouse Research Laboratories). *Metals & Alloys,* Vol. 2, Oct. 1931, pages 240-241.

The author describes apparatus for the determination of the electrical resistance of molten alloys. The use of the induction furnace for the melting of alloys has made such information of use in the design of furnaces for this work. WLC (21)

Vibration-proof Mounting by Means of Air Cushions. (Eine erschütterungsfreie Aufstellung mittels Luftpolsters.) E. Gehrke & B. Voigt. *Zeitschrift für technische Physik,* Vol. 12, Dec. 1931, pages 684-686.

The generally known mounting method according to Julius as well as the mounting device of Müller-Leybold satisfactorily eliminates the horizontal component of the vibration disturbances whereas the vertical components are still occurring. A new method of shock-proof mounting is shown which overcomes both kinds of difficulties so that complete absence of vibrations is secured. The following elements are embodied in the vibration-proof mountings: tennis balls, rubber air cushions, elastic steel rods, damping tanks filled with paraffin oil and containing several metal sheets ("Schlingertank"), and finally a large box to get rid of air current. Three different manners of shock-proof mounting are fully discussed in this paper which was presented at the 7th Deutscher Physiker & Mathematikertag, Bad Elster, Sept. 13-18, 1931. EF (21)

Micro-stereograms and their photographic Evaluation. (Mikro-stereoaufnahmen und deren photogrammetrische Auswertung.) R. Lorenz. (Technische Hochschule Dresden). *Der Papier-Fabrikant,* Vol. 28, Nov. 30, 1930, pages 805-809.

A unique utilization of the Aerokartograph of Hugershoff for stereo measurements is demonstrated by the evaluation of a microscopic sample, and the interest of the metallurgist is attracted by the suggestion of adopting this kind of measurement for the quantitative evaluation of corrosion pits, for the testing of surface smoothness and for crystal measurements. EF (21)

Use of Chrome Steel Articles for Analytical Purposes. (Über die Verwendbarkeit von Chromstahlgefässen zu analytischen Zwecken.) Albert Krüger. *Chemiker Zeitung,* Vol. 55, Sept. 5, 1931, pages 682-683.

Contains 2 references. Casseroles made of V4A steel can be used for NH_4OH and dilute NaOH solutions. They are better suited than glass or porcelain for handling the hydroxides of Fe, Al, Cr, Cu and Ni and $ZnCO_3$. They are also suitable for H_2O_2, Na_2S and Fehling solutions. In Fe and Al determinations made in chrome steel casseroles, no SiO_2 is found in the precipitate. The amount of steel dissolved after boiling solutions of NaOH, KOH, K_2CO_3, $Ba(OH)_2$, Na_2S, KOH + Na_2S, KOH + H_2O_2 was found to be less than the amount of SiO_2 dissolved from glass vessels. CEM (21)

Laboratory Shaking Machine. Nathaniel Herz. *Engineering & Mining Journal,* Vol. 133, Jan. 1932, page 22.

A 32-compartment shaking machine is described and illustrated. It is employed for amalgamation tests and for nearly all cyanide work. WHB (21)

Limits of Microscopy. Beginning of the Molecular Optics (Grenzen der Mikroskopie. Beginn der Molekularoptik). F. Jentsch. *Zeitschrift für Instrumentenkunde,* Vol. 51, Aug. 1931, pages 441-442.

Author aims at the development of an X-ray microscope with the object of extending the present measuring range from 0.2μ to 0.02 μ. EF (21)

Novelties in the Design of Micro-Photographic Apparatus (Ueber neue Wege im Bau von mikrophotographischen Apparaten). F. Hauser. *Zeitschrift für Instrumentenkunde,* Vol. 51, Sept. 1931, pages 483-488.

Refers to microscopes built by the E. Busch Co., Rathenow, Germany, and notes in detail recent developments. (21)

Gauge Checking Laboratory at Stanford University. M. S. Hugo. *Western Machinery World,* Vol. 22, Dec. 1931, pages 535-537.

A description of the building and modern equipment of the gauge checking laboratory at Stanford University under the Ordnance Department of the U. S. Army is presented. The University proposes to maintain an unbiased position by refusing to allow the personnel of the gage laboratory to engage in private consulting work. Charges for gage checking are nominal, just sufficient to cover laboratory costs. (21)

Modern Methods of Metallurgical Testing (Les Méthods moderne d'essais en Métallurgie). M. Favollet. *Aciers Spéciaux, Métaux et Alliages,* Vol. 6, May 1931, pages 220-236; Vol. 6, June 1931, pages 272-292.

In a series of 3 lectures, the author makes a detailed review of all the testing methods, equipment and apparatus used in metallurgical laboratory for control and research. (21)

A Vacuum Technic for the Chemist. K. Hickman. *Journal of the Franklin Institute,* Vol. 213, Feb. 1932, pages 119-154.

Communication No. 489 from Kodak Research Laboratories and presented at meeting of Franklin Institute Feb. 18, 1931. Includes bibliography of 18 references, and 19 diagrams. A manipulation chart for vacuum assemblies for variety of purposes is shown, each set forming an independent unit capable of performing a specific operation. Work of assembly requires nothing more than sealing of 2 or 3 joints. Combinations of apparatus are by no means exhaustive. Phthalate condensation pumps may be coupled to vacuum spectographs and X-ray tubes. Vacuum oven technic may be employed for cathodic spluttering of metals, study of shrinkage of fibers and cellulosic sheets on prolonged desiccation, regeneration of materials like silica gel or animal charcoal. On the Polarization Capacity of Mercury Electrodes (Ueber die Polarisationskapazität von Quecksilberelektroden). T. Erdey-Gruz & G. G. Kromey (Technische Hochschule, Berlin). *Zeitschrift für physikalische Chemie,* Abt. A, Vol. 157, Nov. 1931, pages 213-214.

An electron tube relay is described which in connection with an oscillograph is fitted for taking voltage/time curves under conditions characterized by the nearly complete absence of currents. EF (21)

A New Method for the Inexpensive Manufacture of Reversible Pattern Plates (Neues Verfahren zur billigen Herstellung von Reversiermodellplatten). F. Brobeck. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Nov. 13, 1931, pages 879-887.
Description of a method by which a reversible pattern can be made from a single-sided pattern so that molds can be better utilized, even though only a small quantity are to be made. This method is also suitable for machine molding. Some remarks are made on the estimating of costs of manual and machine molding. Ha (22)

Deep Etching of Brass Applied to Gating Problems. R. W. Parsons. *Metal Industry,* London, Vol. 39, Aug. 21, 1931, pages 177-179; *Metal Industry,* New York, Vol. 29, Nov. 1931, pages 477-480.
From paper given at American Foundrymen's Association, Chicago. Illustrations are given showing that the deep etch test can be useful with problems of gating which have to do with the production of sound castings. See *Metals & Alloys,* Vol. 2, Aug. 1931, page 150. PRK (22)

Electric Brass Furnace Saves Its Cost in Two Years. *Electrical World,* Vol. 99, Jan. 30, 1932, pages 234-235.
An analysis of comparative production costs by the Rockwood Sprinkler Co., Worcester, Mass., for coke-fired and electric equipment shows that the electric furnace paid for itself in 2 years. The furnace employed was of the indirect-arc rotary type made by the Detroit Electric Furnace Co. Operating figures are given. Economy of production, close temperature control and elimination of gas and foreign particles from the melt, feature their operation. WHB (22)

Brackelsberg Process Produces Grey Iron of Higher Quality. *Canadian Foundryman,* Vol. 22, Oct. 1931, pages 7-10.
A very complete description of results obtained during the use of the 2-ton Brackelsberg furnace, accompanied by 3 photographs and 4 tables. OWE (22)

Modern Notions for Jobbing Foundries. A. S. Worcester. *Foundry Trade Journal,* Vol. 45, Oct. 29, 1931, page 276.
In his presidential address to the West Riding of Yorkshire Branch of the Institute of British Foundrymen, the author discusses the desirability of disseminating technical data to the small foundrymen, the desirability of mechanization, the baneful influence of bad costing, and the necessity of improving the personnel of foundries. OWE (22)

High-Strength Sand-Casting Aluminum Alloys. W. C. Devereux. *Foundry Trade Journal,* Vol. 45, Nov. 26, 1931, pages 331-335; Dec. 3, 1931, pages 349-352.
A discussion of the "Y" alloy, the R.R.50 and R.R.53 alloys, and the 4% Cu-Al alloy. Discusses the difficulties which meet the foundryman, owing to competition of drop forgings of these alloys with castings. Deals with the mechanical properties of the light alloys, with the question of the solidification and its relation to the soundness of these alloys, and with their wear and friction characteristics. These points are illustrated by a number of diagrams. Casting properties of these alloys are discussed. Special attention is paid to the necessity for close temperature control of melting and pouring, and to other practical details of the molding of these alloys. The paper is accompanied by 21 diagrams and photographs and 8 tables. OWE (22)

Recent Developments in the Non-Ferrous Foundry Industry. H. C. Dews. *Foundry Trade Journal,* Vol. 46, Jan. 14, 1932, pages 40-42.
The author discusses briefly the work of the British technical societies and of the British Non-Ferrous Metals Research Association. He also discusses the work which has been done on impurities in copper and on spectrographic analysis. The growing importance of Si is dealt with in some detail. Reference is made to the results of work that has been carried out on the corrosion of brass condenser tubes and to the fact that 30% Cu-Ni tubes have proved an unqualified success. Attention is directed to another alloy, Al brass, which is finding use in this service. A brief note as to the importance of Be is appended and some attention is given to foundry developments, particularly to the use of the high-frequency furnace and centrifugal casting machines. OWE (22)

The Laboratory and the Foundry. R. Arzens. *Engineering,* Vol. 132, July 3, 1931, page 10.
Abstract of a paper read before the Institute of British Foundrymen, June 1931. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 279. LFM (22)

The Casting of Pistons for Internal Combustion Engines. R. Fischer. *Foundry Trade Journal,* Vol. 45, Dec. 31, 1931, page 409.
Complete translation of article published in *Die Giesserei.* The article is accompanied by 11 diagrams. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 319. OWE (22)

Moulding Practice for Heat-Treated Aluminium-Alloy Castings. Lewis H. Fawcett. *Foundry Trade Journal,* Vol. 45, Oct. 15, 1931, pages 241-242.
Extended abstract of paper read before the American Foundrymen's Association. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 320. OWE (22)

Cutting Production Costs in the Brass Foundry. James Breakey. *Canadian Foundryman,* Vol. 22, Dec. 1931, pages 7-9, 20.
An article, accompanied by 7 photographs, in which a description is given of the methods used in the Empire Brass Manufacturing Company's plant in the production of cores for their castings. OWE (22)

Pattern Storage—a Simple, Economic Plan. H. V. Butterfield. *Canadian Foundryman,* Vol. 23, Jan. 1932, pages 3-5, 14.
Description of a method of attacking the problem of the organization of pattern storage, accompanied by diagrams indicating types of records that have proved satisfactory. OWE (22)

The Production of Iron Castings on a Semi-Repetition Basis. S. Carter. *Foundry Trade Journal,* Vol. 45, Oct. 29, 1931, pages 276-277.
A discussion of the methods that may be adopted by foundrymen who receive orders for small castings in quantities which do not justify a large capital expenditure as a preliminary outlay. OWE (22)

The Application of Pulverized Fuel to the Foundry Industry. W. Boon. *Foundry Trade Journal*, Vol. 45, Nov. 5, 1931, pages 287-291.

The author deals with the types of pulverizers available and discusses briefly the advantages and disadvantages of these different types. Space is devoted to consideration of the types and characteristics of coal and particularly the effect of moisture on coal which is to be pulverized. Transportation of coal within the works is dealt with. The application of pulverized fuel firing to annealing ovens, chilled-roll furnaces and rotary melting furnaces, the effects of pulverized fuel upon refractories, and the influence of ash are described. A report of the discussion of this paper appeared in the *Foundry Trade Journal* for Nov. 19, 1931, pages 321-322. OWE (22)

Fabrication of Fly Wheels and Pulleys (La fabrication des volants et des poulies). *Commission Technique de l'Association Technique de Fonderie de Belgique, Congres International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie*, 6th session, Liege, June 1930, pages 913-915.

Dry sand moulds are advised. Rather general recommendations are made as to gates, heads and for control of cracking and shrinking. The irons recommended range from 3-3.5% Si and 1-1.3% P for small wheels down to 1.6-1.8% S and 0.3% P for huge fly wheels. HWG (22)

Results of the Work Done by Societies in Foundry Practice. (Ergebnisse der Gemeinschaftsarbeit im Giessereiwesen.) W. Bültmann. *Maschinenbau*, Vol. 10, Feb. 19, 1931, pages 123-125.

A tendency for improved quality and reduction of production costs is evident. The societies' efforts and the general importance of the work is discussed. There is a need for technical and expert advice which presents the problem as to how it is to be obtained. The following variety of subjects are also considered: cast iron and metals, crude and associated materials, production, operation, samples, and labor. MAB (22)

Recent Developments in the Automobile Foundry Industry. Percy Pritchard. *Foundry Trade Journal*, Vol. 46, Jan. 14, 1932, page 24.

Refers to the fact that the major percentage of automobile cylinder blocks manufactured in Great Britain are now being made in green sand and that the urgent demand of engineers for better wearing properties has led to the introduction of special high-test cast irons, some containing up to 5% Ni. The use of centrifugally cast liners is referred to, and the fact is emphasized that heat-treated cast iron, which is hardened after machining but before the final grinding, is being largely used in this connection. Some attention is directed to Al foundry work and particularly to the die-casting of alloys of Al base. Reference is made in particular to a multiple impression die containing 8 impressions, the die weighing 33,500 lbs., probably the largest yet produced. The remarkable development in the use of Mg castings is referred to; this increase in production probably approximates 400 or 500%. An infinite variety of articles is now being produced in this metal. The prices at which these castings are being sold today make them reasonably competitive with Al castings made from virgin material. OWE (22)

Improving Castings with the Double Forehearth. (Gussveredlung und Doppelkammervorherd.) Carl Rein. *Giesserei-Zeitung*, Vol. 27, Jan. 1, 1930, pages 8-11.

Cast iron melted in a cupola can be improved by a complete deslagging. This is accomplished by allowing the melt to stand awhile, so that the slag particles may rise to the top. Where various mixtures are melted in the same furnace, the double forehearth has the advantage of keeping the individual melts separate. It is heated to a white heat with an oil burner before tapping, so as not to cool the charge. (22)

Correlating Design and Foundry. Alex Taub. *Machine Design*, Vol. 4, Jan. 1932, page 41.

Successful coöperation of designer and founder is exemplified by the method used by the Chevrolet Motor Co. Ha (22)

Low Total-Carbon Cast Irons and Their Service to Foundrymen. W. West. *Foundry Trade Journal*, Vol. 45, Oct. 29, 1931, pages 272-275.

After a discussion of the theory of cast iron, the author enters upon a description of the various experiments that have been carried out, showing the relationship between low total C and the combined C and Si contents of cast iron. The effect of low total C upon the liquid shrinkage of iron is dealt with and is illustrated by means of 5 tables. The author believes that these experiments show that liquid shrinkage is only prevented by having the requisite amount of total C present to counteract the shrinkage by its own expansion during solidification, the alternative being to make provision on the casting for risers of sufficient capacity to feed sections where such liquid shrinkage is likely to occur. The article is accompanied by 8 figures. OWE (22)

Commercial Developments in the Light-Castings Industry. Gervais Rentoul. *Foundry Trade Journal*, Vol. 46, Jan. 14, 1932, page 18.

Discusses in some detail the work of the recently organized British Iron Founders' Association, which has been attempting to improve the economic conditions of the foundry industry in Great Britain, particularly in respect to unnecessary cutting of prices. Reference is made to negotiations which are under way between the Association and various merchant associations in Great Britain and Ireland to arrive at an agreement which will ensure fair play to manufacturer, merchant and consumer, alike. OWE (22)

A Contribution to the Permeability for Gases of Molding Sands. (Beitrag zur Frage der Gasdurchlässigkeit von Formsanden.) H. Viez. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Nov. 13, 1931, page 883.

An investigation is reported to define the relation between porosity and permeability for the passage of 1000 m^3 air through a standard sample. The results can be used as basis for practical standardization. Ha (22)

REFRACTORIES & FURNACE MATERIALS (24)

Study of the Shrinkage of Diaspore Clays. Stuart M. Phelps. *Journal American Ceramic Society*, Vol. 15, Feb. 1932, pages 96-106.

The development of methods which will shrink diaspore without firing to exceedingly high temperatures for long periods of time is set forth. Experimental work shows that this can be accomplished by a number of shrinkage-producing materials. It is shown that these should be added in definite percentages, and that the greatest shrinking effect will be produced by fine grinding, high pressure molding of the calcine dobies, and by firing at moderate temperatures. The effect of various gas atmospheres during calcining is pronounced. Commercial brick made by the process developed show properties superior to those of regular diaspore brick. WAT (24)

Refractories Made in Fused State. (Im Schmelzfluss erzeugte feuerfeste Stoffe.) F. Reinhart. *Tonindustriezeitung*, Vol. 56, Jan. 7, 1932, pages 32-34.

The article gives a survey of the various methods which have been proposed and are used to process refractories in fused state. The article in particular refers to patents applied for. GN (24)

High Temperature Insulation. Waldo Hutchinson. *Rock Products*, Vol. 34, 1931, pages 85-86.

Discusses the basic idea of insulation and gives graphs showing heat losses from various surfaces at various temperatures and air velocities. It is stated that air spaces are not insulators at high temperatures, owing to radiation and conversion in the space. For this reason, brick containing pores or voids large enough to be seen with the naked eye are better heat conductors at high temperatures than brick of the same material with smaller pores or no pores at all. Heat conductivity through walls and graphs are given showing the relative conductivities of various materials including fire-brick, red-brick and Sil-O-Cel products at different temperatures. The insulating property of diatomaceous silica is due to its content of as much as 85% of its volume of infinitesimal air cells. Certain calcined grades of it can be used at temperatures as high as 2500° F. Advantages resulting from insulation of furnace installations are saving in fuel, more even temperature distribution, protection of brick-work from rapid temperature changes and cooler working conditions around the furnace. WAT (24)

Structure and Heat Conductivity of Refractory Bricks. (Gefüge und Wärmeleitfähigkeit feuer fester Steine.) E. Maase. *Stahl und Eisen*, Vol. 51, July 2, 1931, pages 860-861.

The porosity of a brick can be represented approximately by the formula $m = 100\ (1-G/\gamma)$, where G is its weight and γ the specific gravity of the principal material of the body. With increasing sizes of the pores the heat transmission increases greatly. Non-metallic, amorphous substances have a low heat conductivity increasing with temperature, crystalline substances, a high heat conductivity decreasing with temperature. The temperature curves of the heat conductivity numbers assume with increasing temperature an increasingly steeper gradient. The heat conductivity increases with increasing temperature at which the brick are burned. Ha (24)

Heating Refractories from "Cold" in Fuel-Fired Furnaces. M. H. Mawhinney (Electric Furnace Co.). *Iron Age*, Vol. 128, Dec. 17, 1931, pages 1556-1559, 1584.

The first of a series of 2 articles dealing with the absorption of heat by the refractory lining of furnaces or other apparatus which is heated by gases resulting from the combustion of a fuel. The results of the tests showed: (1) a furnace to be operated at an average temperature of 1600° F. is "heated up" when the temperature of the lining at a depth of 2 ins. from the inside temperature is 75% of furnace temperature; (2) the time required depends on the rate of firing and final temperature required; (3) the time required for the same rate of firing and the same final temperature is practically independent of the wall construction and the amount of insulation; (4) the amount of fuel required to heat the furnace to a given temperature in a given time is independent of the wall construction; (5) variable rate of firing during heating up, with the highest at the start is more efficient than a constant rate equal to the average of the variable rate; (6) the most efficient average rate of firing for the variable rate, expressed in B.t.u. liberated hourly in the furnace/ft.^{2} of interior area of lining, is about 10,000-12,000 B.t.u.; (7) in gas fired furnaces, the use of gas burners when heating up only, will save time and fuel during heating up periods. VSP (24)

Refractory Materials for the Induction Furnace. J. H. Chesters & W. J. Rees. *Engineering*, Vol. 131, June 12, 1931, pages 775-776; June 26, 1931, pages 844-845.

Condensed from paper read before the Iron and Steel Institute, London, May 1931. See *Metals & Alloys*, Vol. 2, Sept. 1931, page 190. LFM (24)

Welded Zigzag Windings and Refractory Shapes for High-Temperature Furnaces. L. Navias. *Journal American Ceramic Society*, Vol. 14, May 1931, pages 365-375.

A brief account is given of published methods for making high-temperature furnaces using W and Mo windings placed both internally and externally with respect to the furnace tube. Several new methods for furnace construction are mentioned, and details are given of windings and refractories for furnaces reaching 1600° C. and 2000° C. The windings are protected from oxidation by hydrogen. WAT (24)

Modern Refractories Meeting Increased Service Demands. *Steel*, Vol. 88, Feb. 5, 1931, pages 54, 63.

Developments in the refractories industry for the past year include an increase in the amount of monolithic construction used in forging and heating furnaces, a wider utilization of chromite ore refractories and of chromite and magnesite brick, a greater use of fire brick for boiler furnace hearths, the development of acid-resistant refractories for furnaces using fuel oil, and the construction of several specially designed hearths. JN (24)

Steel Industry Using Less Magnesite Refractories. *Steel*, Vol. 89, July 16, 1931, pages 56-59.

The high cost of magnesite has stimulated the use of dolomite and chromite. Some statistics are given. Ha (24)

GASES IN METALS (25)

The Influence of Titanium Tetrachloride on the Gas Content and Grain Size of Aluminum and Some Alloys. W. Rosenhain, J. D. Grogan & T. H. Schofield. *British Aeronautical Research Committee, Reports & Memoranda* No. 1385, Nov. 1929, 10 pages.

The results of experiments to determine the effect of titanium tetrachloride in aluminum alloy castings are discussed. Titanium tetrachloride when passed into molten aluminum appeared to behave in the same way as chlorine and boron trichloride. It reduced the grain size of aluminum castings and did not appear to alter the eutectic structure in the crystal. The reduction in grain size persisted after remelting even when the molten metal was heated to 780° C. It removed gases from, reduced the grain size of, and did not "modify" the 12% silicon alloy. It improved the soundness of cast Y-alloy and decreased the grain size of the cast material. By yielding sound material of fine grain, it enabled cast slabs of Y-alloy 1.5 in. thick to be rolled without the employment of the usual preliminary forging operation. It is concluded that the fine grain produced in Y-alloy by the action of titanium tetrachloride would prove of value both in the production of sound castings for rolling into bars and sections, and for the production of large forgings. WAT (25)

Gas Removal and Grain Refinement of Aluminum Alloys. W. Rosenhain, J. D. Grogan & T. H. Schofield. *British Aeronautical Research Committee, Reports & Memoranda* No. 1387, Jan. 1930, 8 pages.

It has been shown (Report No. 1385) that titanium tetrachloride acted as an effective agent both for gas removal and grain refinement. In this report it is shown that these properties are independent. See *Metals & Alloys*, Vol. 1, Nov. 1930, page 856. WAT (25)

Iron-Hydrogen System (Bemerkung zu dem System Eisen-Wasserstoff). A. Sieverts & H. Hagen (University of Jena). *Zeitschrift für physikalische Chemie*, Sect. A, Vol. 155, July 1931, pages 314-317.

The solubility of H in iron powder was redetermined at 800° and 1000° C. and found to be as large as is the case with iron wire and sheet iron. Discrepancies met with in the measurements of Iwasé are ascribed to the O content which is difficult to entirely eliminate in reduced iron. EF (25)

The Solution of Oxygen in Silver. J. H. Simons. *Journal of Physical Chemistry*, Vol. 36, Feb. 1932, pages 652-657.

An article, accompanied by 2 tables, in which experiments are described that indicate that the O retained by rapidly cooled Ag is in the form of silver oxide and not atomic oxygen. The assumption that the O so dissolved is present as silver oxide is used to explain the solution of O in molten Ag and in solid Ag. The solubility curve of silver oxide in solid Ag has been calculated. OWE (25)

The Absorption of Nitrogen by Iron (Die Absorption von Stickstoff durch Eisen). A. Sieverts. (University of Jena.) *Zeitschrift für physikalische Chemie*, Abt. A, Vol. 155, July 1931, pages 299-313.

The absorption ability of α, β and γ Fe for N_2 at atmospheric pressure in relation to the temperature is as follows:

°C.	750	890	910	1000	1050	1100	1150	1190
	α	β	γ					
mg. N_2/100 g Fe	0.4	2	25.0	22.5	21.1	19.8	18.5	(18.2)
N : 10,000 Fe (atoms)		0.8	10.0	9.0	8.4	7.9	7.4	(7.3)
Vol N_2/1 Vol Fe		0.13	1.57	1.41	1.33	1.24	1.16	(1.14)

Fe saturated with N retains varying quantities of N depending on the conditions of cooling-down and on the relative size of the metallic surface. The maximum value amounts to about 0.03% N. The diffusion rate of nitrogen dissolved in iron decreases with falling temperatures and is minute below 600° C. At constant temperatures the amount of nitrogen absorbed by γ Fe proved to be proportional to the square root of the N pressure. EF (25)

The Influence of Atmosphere on the Scaling of Mild Steel. W. H. Blackburn & J. W. Cobb. *Blast Furnace & Steel Plant*, Vol. 19, Feb. 1931, pages 273-276.

The object of the present investigation was to determine, by laboratory experiments carried out under carefully controlled conditions, what steps could be taken to reduce the amount of scaling of a mild steel having regard to fuel economy and also to the possibility of reducing or eliminating the smoke nuisance consequent on the use of a smoke flame. See *Metals & Alloys*, Vol. 2, Dec. 1931, page 323. Ha (25)

Oxygen in Cast Iron. *Metallurgist*, Oct. 1930, pages 152-154.

A critical review of a large number of references on the effect of O in cast iron. VVK (25)

Effects of Furnace Atmosphere. J. A. Comstock. *Heat Treating & Forging*, Vol. 17, Sept. 1931, pages 899-902, 905.

A review of the effects of oxidizing, reducing and neutral atmospheres and means of obtaining and controlling them. Ha (25)

The Influence of Cyanogen Upon Zinc (Ueber die Einwirkung von Cyan auf Zink). H. Braune (Technische Hochschule Hanover). *Zeitschrift für physikalische Chemie*, Bodenstein Festband, 1931, pages 415-422.

The reaction speed of the reaction between solid Zn and cyanogen gas, which attacks metals even at low temperatures, has been determined over the temperature range from 0°-115° C. The activation heat of the reaction considered amounts of 13.4 kcal. EF (25)

Effect of Carbon Gases on Steel. Murray Winter & P. B. Crocker. *Heat Treating & Forging*, Vol. 16, Nov. 1930, pages 1450-1451.

A series of tests were conducted to determine the effect of C gas on the surface condition of high speed steel when heated preparatory to hardening. It appears that the proper atmospheric condition demands a considerable percentage of carbon monoxide, about 25-30%, if scale and soft surface is to be avoided. For this reason, electrically heated furnaces filled with hydrocarbon gas did not give very satisfactory results. Ha (25)

INSPECTION (26)

Gages for Sheet Metal. *National Bureau of Standards Circular* No. 391.

Stock sizes of metal sheets and plates are based either on definite thicknesses or definite weights/unit area. Such a list of thicknesses of weights constitutes what is known as a "gage." In the United States there are several gages in use for sheet metal, a situation which frequently causes confusion and inconvenience in the trade. In order that definite information covering the entire field might be available, the *National Bureau of Standards* has issued *Circular* No. 391, which presents customary practice as to standard thicknesses, weights, and tolerances of sheet metal. It is not the purpose of the circular to promulgate standards, although some of the gages included are officially recognized standards, but merely to make readily accessible information as to current practice. The gages dealt with are those which apply to the following metals and alloys: wrought iron, steel, commercially pure open-hearth iron, saw steel, zinc-coated or galvanized iron and steel, tin plates, terneplates, Cu, Al, brass and other nonferrous alloys, Monel metal, Zn and Pb. The circular also includes gages or stock lists for sheet metal widely used in Europe, particularly England, France, Germany, and in Japan. Copies may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C., at 10 cents each. WAT (26)

Testing of Pre-Heater Parts. (Abnahme von Vorwärmerteilen.) Nürnberger. *Die Wärme*, Vol. 54, Apr. 25, 1931, pages 326-328. Sonderheft "Werkstoff und Herstellung im neuzeitlichen Dampfkesselbau."

The materials used for the construction of pre-heaters and their testing are discussed in this lecture before the Zentralverband der Preussischen Dampfkessel Überwachungs-Vereine, 1931. EF (26)

Acceptance Tests of Gear Steel. *Metal Progress*, Vol. 18, Dec. 1930, pages 91-94.

Details of Brown-Lipe-Chapin methods of inspection of steel for automotive gears are given covering features of cleanliness, structural normality, grain size, hardenability and chemical analysis. WLC (26)

Building and Inspecting Boilers for the U. S. Navy. W. A. Brooks. *Boiler Maker*, Vol. 31, June 1931, pages 146-150.

The procedure followed in equipping a naval vessel with boilers and the requirements which such boilers must meet are described. Materials and test methods are discussed. Ha (26)

Simple Methods for Inspecting Spring Steels. H. J. Malafey. *Machinery*, Vol. 75, July 1931, pages 865-866.

Description of a portable equipment for applying hardness tests to hardened and tempered spring steel specimens for the purpose of determining the strength and quality of purchased stock. A table showing the effect of heat treatment on the hardness at different tempering temperatures is given. Ha (26)

Measurements in Mass Production. (Messungen im Austauschbau.) G. Berndt. *Archiv für Technisches Messen*, 1931, pages T53-54, Section V83-0.

In order to safeguard the exchangeability of parts produced in quantity, tolerances are specified which must be strictly observed. The fundamentals and definitions of units and the technical measuring system are explained and the errors due to observation and to measuring instruments discussed. The importance of the German DI-standards is pointed out. Ha (26)

Radiographic Inspection of Welded Structures. H. R. Isenburger. *Boiler Maker*, Vol. 31, Oct. 1931, pages 258-263.

The high voltage equipment for X-ray inspection is described and defects in welds explained by means of micrographs. An exposure chart, times required for different thicknesses of steel is added. Ha (26)

Results of X-Ray Tests of Pressure Gas Containers. (Ergebnisse von Röntgenprüfungen an Druckgasflaschen.) C. Kantner & A. Herr. *Autogene Metallbearbeitung*, Vol. 25, Jan. 15, 1932, pages 17-25.

Tests on the density and metallographic examinations of steel containers for compressed gases are discussed and critically reviewed with respect to the safety of such containers; in general, former observations on the same subject are corroborated. The experiments made over a number of years permit the conclusion that the X-ray tests of pressure containers can be made safely and quickly with simple arrangements and should be checked by metallographic investigations. The processes used in the manufacture of the containers can be recognized by exposures of the bottom; the characteristics of each process and of defects as they appear in the X-ray picture are described and illustrated. Ha (26)

Weighing Thin Sheets to Measure Thickness. F. V. Hartmann. *Machinery*, Vol. 37, Feb. 1931, pages 430-432.

Metal sheets of Al 0.00025 in. thick were weighed to determine their thickness because they could not be measured exactly enough. A special press was developed to cut the specimens so accurately that the error in weighing them for the calculation of the thickness is negligible. Ha (26)

Magnetic Testing of Pipe Welds is New Inspection Method. H. R. Simonds. *Steel*, Vol. 88, Mar. 5, 1931, pages 39-42.

A magnetic testing outfit built by the Ferrous Magnetic Corporation, New York, is described for magnetic and X-ray testing; photographs are shown and the defects pointed out. Ha (26)

Detecting Defects in Heavy Castings by the Gamma Ray. *Foundry Trade Journal*, Vol. 45, Dec. 24, 1931, page 398.

A brief article outlining the recent developments by Mehl in the use of gamma rays for examination of heavy castings. OWE (26)

EFFECTS OF ELEMENTS ON METALS & ALLOYS (27)

The Influence of Chemical and Physico-chemical Reactions at the Surface of High-melting Metals on the Thermal Emission of Electrons. (Der Einfluss chemischer und chemisch-physikalischer Vorgänge an der Oberfläche hochschmelzender Metalle auf die glühelektrischen Eigenschaften.) K. Becker. *Physikalische Zeitschrift*, Vol. 32, July 1, 1931, pages 489-507.

The effect of gases (H, N, O, Ar), electro-positive (Hg, alkaline and earth alkaline) and electro-negative vapors (H_2O, P, I) and of oxides (of Th, Yt, La, Ce, Zr, U) on the thermal electron emission of high melting metals is reviewed. Four different types of phenomena due to chemical and physico-chemical reactions of foreign atoms encountered at the surface of high melting metals are specified. 94 references. EF (27)

Titanium in Rail Steels (Le titane dans les aciers à rails). *Aciers Spéciaux, Métaux et Alliages*, Vol. 6, Apr. 1931, pages 191-192.

Ti in steel reduces the segregation in the center. Usual amount of Ti in steel is just below 0.10%. GTM (27)

Alloy Cast Irons. Gerald S. Bell. *Foundry Trade Journal*, Vol. 45, Dec. 3, 1931, pages 353-354; Dec. 10, 1931, pages 365,368.

A general article on the subject of alloy cast iron, in which the effects of Ni in gray iron are dealt with, and in which the applications of pearlitic Ni cast iron are discussed. The effects of Cr additions to cast iron are dealt with, and the necessity for controlling the ratio of Cr to Ni to suit the class of casting being poured and the desirability of making allowance for the Ni and Cr content in the Si content of the basic mixture is referred to. The article is accompanied by two photographs. OWE (27)

The Effects of Impurities on Copper. Part VII.—The Effect of Antimony on Copper. Part VIII.—The Combined Effect of Antimony and Arsenic on Copper. S. L. Archbutt & W. E. Prytherch. *Engineering*, Vol. 131, June 12, 1931, pages 777-779.

Condensed from Communication from The National Physical Laboratory, read before the Institute of Metals, London, March 12, 1931. See *Metals & Alloys*, Vol. 2, June 1931, page 121. LFM (27)

Investigations on the Restriction in Using Gray Cast-Iron of Various Compositions. (Untersuchungen über die Einschränkung im Gebrauch von Grauem Gusseisen verschiedener Zusammensetzung.) E. Balma. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Dec. 4, 1931, page 922.

The objections against gray-iron in the construction of motors are shown to no longer be valid since an addition of Cr and Ni produces very suitable material. Both elements must be present, the best and most economic is a high content of Cr and a low of Ni. Ha (27)

The Influence of Silicon on Nickel Steel. R. Harrison. *Engineer*, Vol. 152, Oct. 2, 1931, pages 347-348.

Abstract of a paper read before the Iron & Steel Institute, Swansea, Sept. 1931. See *Metals & Alloys*, Vol. 2, Dec. 1931, page 323. LFM (27)

Foundry Research in 1931. Harold Hartley. *Foundry Trade Journal*, Vol. 46, Jan. 14, 1932, pages 21-23.

An article dealing in the main with the work carried out in 1931 by the British Cast Iron Research Association. Special attention is directed to the recent discoveries regarding the effect of Si upon gray iron, particular note being made of the recently developed heat-resisting alloy "Silal." The influence of total carbon upon the properties of iron is referred to, and the conditions of melting are carefully discussed. The effects of Ni and Cr are then dealt with, and attention is directed to a high Si iron similar to "Silal" in Si and C content but containing Cr and Ni. Two photomicrographs of typical sections of this alloy accompany the article. The question of the soundness of castings is referred to, and a discussion of the test bar problem concludes the article. OWE (27)

Silicon as an Alloying Element. J. Arnott. *Engineering*, Vol. 132, July 3, 1931, page 10.

Abstract of a paper read before the Institute of British Foundrymen, June 1931. See *Metals & Alloys*, Vol. 2, Nov. 1931, page 282. LFM (27)

Role of Sulphur in Corrosion Resistant Steels. Correspondence from F. R. Palmer, Reading, Pa. *Metal Progress*, Vol. 21, Feb. 1932, pages 70 and 88.

The effect of S up to 0.30% in stainless steels to improve their machining properties is discussed. WLC (27)

Effect of Composition on Aluminum-base Die-casting Alloys. D. L. Colwell. *Proceedings American Society for Testing Materials*, Vol. 31, Pt. 1, pages 268-279.

Aluminum Improves Malleable Cast Iron Properties. John H. Hruska. *Foundry*, Vol. 59, Jan. 1, 1931, pages 70-71.

An addition of 0.04% Al to malleable iron resulted in a maximum increase of tensile strength and elongation (53,900 lbs./in.^{2} and 21% for 2 ins., respectively). With larger additions, the fluidity of slag and metal was influenced; both became more sluggish with increasing amounts of Al. Ha (27)

Aluminum, Chromium and Manganese in Gray Cast Iron. (Aluminium, Chrom und Mangan in Grauguss.) E. R. Thews. *Die Metallbörse*, Vol. 21, Feb. 7, 1931, pages 244-245.

The present state of Al, Cr and Mn additions to gray cast iron is reviewed as reflected by statements in literature. 25 references. EF (27)

Vanadium has Marked Effect on Properties of Steel. *Steel*, Vol. 89, July 23, 1931, page 33.

V acts both as a scavenging agent to clean the molten bath and as an alloy in the finished metal; the first action consists in uniting with undesirable O and N and carrying them off in the slag. As an alloying material it increases strength, hardness and resistance to abrasion and fatigue; the tendency of the elements to segregate during the cooling period is decreased. The properties are discussed more in detail. Ha (27)

INSTRUMENTS & CONTROLLERS (28)

Electrical Instruments Uncover Hidden Shop Losses. A. G. Baumgartner (General Electric Co.). *Iron Age*, Vol. 128, Dec. 17, 1931, pages 1537-1542, 1584.

Gives a detailed picture of the application of electrical devices to machines as well as other uses in the plant. Absorption dynamometers function not only in the capacity of supplying loads for a machine but also provide the means of measuring the load. In this group are placed the Prony brake, hydraulic and fluid friction brakes, fan brakes, electromagnetic and electric brakes. Principal forms of transmission dynamometers are the levers, torsion and cradle types. Indicating instruments give the momentary value of quantity which they are measuring. Indicating instruments in general are applied to loads which are relatively constant for appreciable intervals. Recording instruments, in general, are instruments so arranged that accurate records of needle fluctuations are obtained. Various applications of electrical instruments in the machine tool field are described. VSP (28)

Photoelectric Tubes Control Sheet Mill Run Out Tables. A. F. Bowers. *Steel*, Vol. 89, Aug. 20, 1931, page 38.

The layout of the installation is described. Ha (28)

Practical Measurement of Time of Impact for the Determination of Steam Consumption in a Manual Forge. (Praktische Erprobung der Schlagzeitmessung zur Ermittlung des Dampfverbrauchs in einer Freiformschmiede.) W. Mecklenbrauck & Walter von Chilingensperg. *Stahl und Eisen*, Vol. 51, Jan. 8, 1931, pages 49-51.

The electrical and mechanical devices arranged on a steam hammer in order to measure as exactly as possible impact time and the time during which the hammer was actually under steam in order to gain more definite values of the steam consumption for a certain forging operation are described in detail and records reproduced. Ha (28)

Temperature Measurement—Electrical and Optical Devices Used in Pyrometry. P. M. Hogg. *Electrician*, Vol. 107, Nov. 27, 1931, pages 736-738.

An abstract of an address on "The Application of Electricity to the Measurement of Temperature, "read before the Mersey and North Wales (Liverpool) Center of the Institution of Electrical Engineers, Oct. 19, 1931. The types of pyrometry reviewed are: resistance, thermo-electric, and radiation. The latter may be divided into (1) total radiation pyrometry and (2) optical pyrometry. WHB (28)

The Measurement of the Gaseous Products in the Foundry. (La Mesure des Débits Gazeux en Fonderie.) H. Laplanche. *Revue de Fonderie Moderne*, Vol. 25, Dec. 25, 1931, pages 453-463.

The desirability of determining quality and quantity of gases escaping from the foundry with regard to whether too much or too little air is used in certain combustion processes is discussed and the different methods and principles of measuring gas flow and metering instruments are described. Ha (28)

Temperature Measuring Instruments in Foundries. (Temperatur Messgeräte in Metallgiessereien und Schmelzwerken.) *Die Metallbörse*, Vol. 20, Nov. 8, 1930, pages 2491-2492; Nov. 22, 1930, page 2588; Nov. 29, 1930, pages 2635-2636; Dec. 6, 1930, pages 2683-2684; Dec. 13, 1930, pages 2732-2734; Jan. 3, 1931, page 5, Jan. 10, 1931, pages 52-53.

A most complete review of the present state of temperature measuring technique with reference to metallurgical melting processes and foundry operations is given comprising the following types of instruments: (1) mercury thermometer, (2) electric resistance thermometer, (3) thermoelectric pyrometers and (4) total radiation and optical pyrometers. The paper contains 25 illustrations and 12 references. EF (28)

Thyratron Tubes Maintain Tension in Wire Drawing Equipment. *Steel*, Vol. 89, July 16, 1931, page 54.

The re-reeling coils are driven by a direct-current motor whose speed is controlled by a thyratron tube which lets more or less current pass to make the speed of the motor conform to the drawing speed of the wire. Ha (28)

Remote Metering in Steel Mills. II. The Application of the Electric Remote Metering Methods (Fernmessen auf Eisenhüttenwerken. II. Die Anwendung der elektrischen Fernmessverfahren). B. von Sothen. *Archiv für Eisenhüttenwesen*, Vol. 5, Aug. 1931, pages 81-93.

Report 153 of the Committee on Heat of the Verein deutscher Eisenhüttenleute. The paper deals with the application of the electric remote metering methods in metallurgical plants, such as blast furnace plants, open hearth plants, rolling mills, gas producer plants and Thomas steel plants. It also deals with the equipment for controlling heat, gas, water, compressed air and electric current. A detailed illustrated description is given of the various devices that are employed and suggested for the above purposes with special reference to the equipment that has been installed in the various plants of German steel mills. The paper notes the possibilities of development in the field of remote metering devices. GN (28)

Precision Measuring Instruments Used by the German Machinery Industry. O. P. van Steewen. *American Machinist*, Vol. 75, Oct. 22, 1931, pages 620-622, Oct. 29, pages 666-668, Nov. 5, pages 704-707.

2 main expedients to manufacture with greater economy were used in Germany: (1) systematic establishment of standards by the German Industrial Standardization Committee; (2) enlistment of the optical industry for the purpose of cheapening and simplifying measuring methods. The latter measure consisted in refining the inspection methods in order to exclude the personal factor and obtain closer tolerances. A great number of gages, microtasts, internal gages, gear testers, etc., are described and their function explained. Ha (28)

Temperature Measurement on Liquid Cast Iron (Temperaturmessung an flüssigem Gusseisen). J. Möller. *Dinglers Polytechnisches Journal*, Vol. 345, Nov. 1931, pages 206-208.

Problems associated with the temperature measurement of cast iron and use of the "Pyropto" instrument, built by the Hartmann & Braun Co., Frankfurt. EF (28)

EFFECT OF TEMPERATURE ON METALS & ALLOYS (29)

The abstracts in this section are prepared in coöperation with the Joint High Temperature Committee of the A.S.M.E. and the A.S.T.M.

Zinc Alloys for High- and Low-Temperature Service. H. A. Anderson (Western Electric Company). *Symposium on Effect of Temperature on Metals, A.S.T.M.—A.S.M.E. Joint Research Committee*, 1931, pages 271-289.

Boiler Material which is only slightly Subject to Aging. (Gering alterunge empfindliche Kesselstoffe.) E. Franke. *Die Wärme*, Vol. 54, Jan. 3, 1931, pages 6-7.

The phenomenon of aging is briefly anticipated and it is shown why ordinary wrought iron is unfitted for highly stressed boiler plate. Among the boiler material which displays minor tendencies towards aging are the Izett Steel, low alloyed Ni-steels, low C wrought iron with additions of V or Mo and the Cu-bearing Union Baustahl. These are discussed with reference to their superior properties as boiler plate. In conclusion attention is called to the smaller wall thickness if alloy steel is employed and to the testing for aging of material in the as-received state. EF (29)

Methods of High Temperature Treatment. Paul P. Cioffi (Bell Telephone Laboratories). *Journal Franklin Institute*, Vol. 212, Nov. 1931, pages 601-612.

Treating metals, chiefly iron and its alloys, at all temperatures up to 1700° C. and in any atmosphere ranging in pressure from 10^{-8} mm. of mercury to 20 or more atmospheres is discussed. There are 3 rather well defined groups: (1) Long ores and tapes heated to any temperature up to a few degrees below the melting point by passing currents through them in the presence of a gas; (a) under a pressure of 1 atmosphere or less; (b) under a pressure up to 20 atmospheres. (2) Toroids heated by induction in a gas atmosphere, with the gas pressure ranging from 10^{-8} mm. to 1 atmosphere. (3) Any shape of specimen heated up to about 1700° C. (in a molybdenum wound furnace) in a gas pressure from 10^{-3} mm. to 20 atmospheres. Heat treating iron in vacuum and in hydrogen has been accomplished satisfactorily over a period of years. Illustrations of heat treatments are given. DTR (29)

Engineering Requirements and Trends for Metals in the Non-Ferrous Roasting, Smelting and Refining Industry. R. E. Brown (Electro Metallurgical Sales Corp.). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee*, 1931, pages 151-168.

The Behavior of Steel at High Temperatures. *Engineering*, Vol. 152, July 31, 1931, pages 115-116.

From report of the Engineer-in-Chief, V. B. Harley Mason, to the Executive Committee of the Manchester Steam Users' Association. Reviews various standard methods of testing and compares the results of different investigators. Test results for ordinary C steel are compared with those for alloy steels. LFM (29)

The Thermal Conductivities of Certain Approximately Pure Metals and Alloys at High Temperatures. L. C. Bailey. *Proceedings Royal Society,* Vol. 134A, Nov. 1931, pages 57-76.

In the case of pure metals the generally accepted rule, that the conductivity decreases with increase of temperature, does not appear to hold in all cases. The conductivity of Al appears to reach a maximum at 225° C., after a decrease takes place to 550° C. The conductivity of Ag is a minimum at about 400° C., after which a rise occurs to 575° C. No other values appear to be given for Ag at these temperatures. The conductivity of Zn appears to decrease continually over a wide range of temperature from -170° to + 370° C. These results and those for Al support the view that the thermal conductivity of a metal increases as the purity of the metal increases. The results for Cd indicate that an abrupt fall and rise of conductivity takes place near 50° C., after which the normal steady decrease occurs. A transition point, reputed to occur at 64.9° C. may have some connection with the change, but further work is necessary to test this. In the case of the 2 alloys tested, the rule that the conductivity increases with increasing temperature is confirmed, but the increase is not regular. The conductivity of brass increases rapidly with temperature, an approximately linear law being followed to about 125° C., after which it tends to a constant value up to 450° C. A continuous increase of conductivity of Platinoid (composition approximately that of German silver) occurs with increase of temperature, an approximately linear law being followed. WAT (29)

"Kanthal" Metal. *Jernkontorets Annaler,* Vol. 115, Oct. 1931, pages 544-547.

"Kanthal" metal is an alloy containing 60% Fe and the balance Cr, Al and Co (percentage of alloying elements not given). The structure is ferritic and is not affected by heat treatment. Its melting point is between 1650° and 1670° C. The tensile strength at room temperature is 119,000 lbs./in.^{2} with 13% elongation and 65% reduction of area. At elevated temperatures the tensile strength is:

	lbs./in.^{2}
700° C.	16800
900° C.	4600
1170° C.	1000
1300° C.	600

Between the temperatures of 700° and 1100° C., the electrical resistance is about 25% more than that of Ni-Cr-Fe alloys containing over 50% Ni and 20% Fe. If the life of an alloy containing 80% Ni and 20% Cr is estimated, for comparison, to be 35 hrs. from a viewpoint of oxidation, at 1200° C., the life of "Kanthal" metal is estimated to be between 80 and 95 hrs. WAT (29)

The Yield Point and Creep Limit of Steel at High Temperatures. *Engineering,* Vol. 132, Aug. 14, 1931, pages 203-204.

An editorial reviewing the work of Baumann, Körber and Pomp, Bailey, Hatfield, and others pointing out that there is no such thing as a true "creep limit." Greater refinements in measurement and tests of longer duration have shown that creep does in fact take place at stresses much lower than those which had at one time been regarded as limiting values. WAT (29)

Safe Internal Pressures for Aluminum Alloys and Tempers at Various Temperatures. *Data Sheet, Aluminum Company of America,* Nov. 6, 1931.

Tables and formulas are given for use in calculating the safe internal pressure for aluminum tubing and pipe (size ⅛" - 2") in various alloys and tempers, at temperatures from 75°-500° F. WAT (29)

The Mechanical Properties of Metals at Elevated Temperatures. Pierre Chevenard (Soc. Anonyme de Commentry-Fourchambault et Decazeville). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee,* 1931, pages 245-270.

For abstract of paper see *Metals & Alloys,* Vol. 2, Sept. 1931, page 191. In the discussion the Crane Company presents data on a low C steel showing results of a variable-temperature constant-load flow test. In such a step-temperature test, it is stated, 3 different stresses generally suffice to show quite well the temperature-stress-creep relationship of a metal. It is further claimed for this type of test that it reveals more clearly the temperatures at which the properties of a metal change from elastic to "viscous." In the author's closure it is pointed out that the results of such tests should be interpreted from a scientific standpoint with caution because at different temperatures under the same load the metal is not in the same condition. On the other hand from the industrial point of view the technique of such tests is of practical value when it is a matter of proceeding rapidly in the study of many metals and alloys. WAT (29)

The Maximums of the Isotherms of Electrical Conductivity of Metallic Solid Solutions (Die Spitzen auf den Isothermen der elektrischen Leitfähigkeit metallischer Mischkristalle). G. Grube & J. Hille. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 194, Dec. 9, 1930, pages 179-189.

Discussion of the conductivity isotherms for different temperatures in a continuous binary series of solid solutions. A compound is formed at decreasing temperature, which, in its turn, also forms solid solutions with the components. The 3 possible constitutions are discussed. The formation temperature of the compound A_mB_n, on account of the formation of solid solutions with the components A and B is (1) reduced by both components, (2) increased by both components, (3) reduced by one and increased by the other component. Case (1) exists in the system Au-Zn and Au-Cu. Case (2) has never been observed. Case (3) occurs in the system Cd-Mg. The relation of these phenomena with the peaks of the conductivity isotherms is discussed. Ha (29)

NCT3—A Recent Addition to the Heat Resisting Alloys. John L. Everhart. *Power,* Vol. 75, Feb. 2, 1932, page 174.

This material contains a maximum of 0.20 % C, 0.70 Mn, 0.03 S and P, 2.0 Si, 23.0-27.0 Cr and 17.0-21.0 Ni. Six months' exposure to hot flue gases, but not exposed to the flame, showed only slight scale formation at 1500° F. WAT (29)

Metal Coatings and Alloys, Resistant to High Temperatures. (Metallschutz und Legierungen, Widerstandsfähigkeit gegen hohe Temperaturen). W. Obst. *Feuerfest Ofenbau,* Vol. 7, Mar. 1931, pages 36-37.

The process of aluminum coating materials, called by Krupp "alitieren," (similar to "calorizing") is advocated. At 850° C. the Al-coated steel is said to have 10 times the life of uncoated steel. Cast iron of low graphite content may be coated after preliminary annealing at 750° C. to avoid further growth. Some general statements, but no details, are given as to Al coatings on Ni, Cu and brass. The Al-coated materials do not serve for as high temperatures as do the 18-8 steels, but the latter are more expensive. Obst states that further advances may be made through Al-Be alloys of 1280°-1300° C. melting point and high heat-resistance. WHB + HWG (29)

Influence of Unequal Heat Expansion of Rigid Connections Between Light Metal and Steel (Der Einfluss der ungleichen Wärmeausdehnung der Verbindung von Leichtmetall und Stahl). E. Straube. *Zeitschrift für Metallkunde,* Vol. 22, Sept. 1930, pages 314-315.

Numerical calculation of stresses due to different heat expansions. Checking by experiments on girders of steel-Lautal. EF (29)

Effect of Carbon and Silicon on the Growth and Scaling of Grey Cast Iron. A. L. Norbury & E. Morgan. *Iron & Coal Trades Review,* Vol. 122, June 26, 1931, page 1023.

Paper read before the Iron & Steel Institute, May 1931. See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 27. Ha (29)

New Creep-testing Apparatus at the Massachusetts Institute of Technology. F. H. Norton & J. B. Romer. *Proceedings American Society for Testing Materials,* Vol. 31, pt. 1, 1931, pages 129-135, 6 figures.

Some improvements over the creep outfits formerly used at Mass. Inst. Tech. are described. Each specimen now has its individual furnace. Winding of the furnace is such as to hold the temperature variation over the test length of the specimen within a range of 20° F. HWG (29)

High Pressures and Temperatures for Steam Prime Movers. O. Wiberg. *Engineering,* Vol. 133, Jan. 1, 1932, pages 27-28.

The results of an analysis of certain tests of materials conducted by the Stal Turbine Co. of which the author is chief engineer, are presented. The following steels were tested: (1) 0.15% C, (2) 0.50% C, (3) 0.35% C, 13.5% Cr, (4) austenitic Cr steel (Krupp V2A), (5) austenitic Cr steel (Firth H. R. Crown), (6) heat resisting alloy containing 15% Cr, 61% Ni, 7% Mo, 15% Fe and 2% Mn. These materials were tested in creep, short-time tension, and fatigue to temperatures up to 700° C. Diagrams illustrate the results. WAT (29)

Use of Metals at Elevated Temperatures in the Ceramic Industry. Clyde E. Williams (Battelle Memorial Institute). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee,* 1931, pages 201-217.

For abstract of paper see *Metals & Alloys,* Vol. 2, Sept. 1931, page 192. In the discussion it was pointed out that imperfect castings have probably been the greatest single cause of trouble in the service of cast furnace parts. The superiority of cast materials over wrought materials of the same composition for elevated temperature service is also pointed out. WAT (29)

Calculation of the Temperature of Combustion of a Few Metals (Versuch zur Berechnung der Verbrennungstemperatur einiger Metalle). Ilja Westerman. *Metall und Erz,* Vol. 27, Dec. 1930, pages 613-619.

The temperatures of combustion for various metals are determined by plotting the heat content of the metal as a function of temperature. A line is drawn from the ordinate corresponding to the heat of combustion of the metal, and the abscissa corresponding to the point where this intersects the heat-content curve represents the combustion temperature of the metal. The following results were obtained: Pb 1470° C., Sn 1950° C., Zn 1800° C., Cd 1385° C., Bi 1890° C. WAT (29)

Properties of Copper and Some of Its Important Industrial Alloys at Elevated Temperatures. W. B. Price (Scovill Manufacturing Company). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee,* 1931, pages 340-367.

For abstract of paper see *Metals & Alloys,* Vol. 2, Sept. 1931, page 231. In the discussion the American Brass Company presents additional data on short-time tensile tests, between room temperature and 610° F., on 17 alloys of Cu containing various amounts of Zn, Sn, Fe, Ni, Pb, and Al. Cu is not recommended for use at elevated temperatures as it begins to anneal at 300° F. and is completely annealed at that temperature in about 96 hours. If heated in air, begins to oxidize at 750° F., and above this temperature begins to scale. If the metal contains oxide it is seriously embrittled in atmosphere of hydrogen at elevated temperatures, but deoxidized Cu and its alloys are not affected by hydrogen in this way. Short-time tensile strength data are given by the Crane Company on yellow brass, red brass, and cast bronze for temperatures between room temperature and 800° F. Al bronzes, containing 9 to 10% Al, have the strength at 1650° F. that ordinary 5% Sn bronze has at room temperature; the Al bronzes do not scale at this temperature. Cu-Ni alloys retain more strength at high temperatures than most other Cu alloys. A chart is given showing the short-time tensile strength of a 70-30 Ni-Cu alloy (Monel), between room temperature and 1500° F. A Cu-Si-Mg alloy (Everdur), retains one-half its original strength at 750° F. A Cu-Ni-Al-Si alloy, (Tempaloy) has good physical properties to 840° F. A comparison is made of the short-time tests and creep tests on Monel metal between room temperature and 1300° F. and short-time tensile properties, including proportional limit, of 8 alloys of Cu, containing various amounts of Ni-Zn-Fe and Mg, are given for temperatures up to 1000° F. Creep tests at 500° F on three alloys containing (1) 88% Cu, 10 Sn, 2 Zn, (2) 88 Cu, 6 Sn, 4 Zn, 2 Pb, and (3) 85 Cu, 5 Sn, 5 Pb are reported from the Lunkenheimer Company. WAT (29)

On the Resistance of Lead and Tin to High Frequency Currents at Superconducting Temperatures. J. C. McLennan. *Transactions of the Royal Society of Canada*, 3rd Series, Vol. 25, Sec. 3, May 1931, pages 191-193.

The author points out that as a result of an interesting observation on the behavior of Pb it appeared desirable to investigate whether there was any actual difference between the temperature at which superconductivity appeared with rapidly alternating currents and that at which it came on when direct currents were used. In the case of Pb it had been shown that with currents of frequency 1.1×10^7 per second an abrupt loss of resistance of relatively large amount occurred at a temperature slightly lower than the critical temperature 7.2° K, characteristic of the transition to superconductivity found for the metal with direct current. Experiments with Sn revealed the fact that with direct currents the resistance began to decrease abruptly at 3.76° K, disappearing completely at 3.70° K. The same Sn, with currents of frequency 1.1×10^7, gave for the corresponding temperatures 3.67° K and 3.61° K—i.e., superconductivity did not begin to appear until a temperature was reached that was below the one at which it was complete in the case of the direct current experiments. A brief discussion of possible explanations of these phenomena follows. OWE (29)

On the Dilatation of Superconductors. J. C. McLennan, J. F. Allen & J. O. Wilhelm. *Transactions of Royal Society of Canada*, 3rd Series, Vol. 25, Sec. 3, May 1931, pages 1-12.

The authors, desiring to answer the question, whether Pb maintained at a temperature of 4.2° K and subjected to a magnetic field sufficient in strength to restore its resistance, would undergo a change of length of the same character and of the same amount that it exhibited when its temperature was raised from 4.2° K to 7.3° K without any magnetic field being present, studied the thermal and magnetic dilatation of Pb and of Rose's metal in the neighborhood of liquid helium temperatures. Both these materials have conveniently high super-conducting points. Materials having high transition temperatures were necessary, since optical and other considerations made observations through liquid helium impossible; temperatures above 4.2° K had to be employed. The results of the investigation on thermal expansion were not as satisfactory as might have been possible, had apparatus of high sensitivity been available. A somewhat higher accuracy was obtained in the measurements of magnetic dilatation. The apparatus used by the authors is fully described and diagrams referring to it are included. The paper is illustrated by 5 diagrams and is accompanied by 2 tables. OWE (29)

Tests on Enduro Firebox Plate. H. L. Miller. *Boiler Maker*, Vol. 31, May 1931, pages 127-128.

Comparative tests with a regular sheet equipped locomotive showed that the carbon steel plate had deteriorated sufficiently after 69,400 miles of service to necessitate removal, while the Enduro plate (a high-chromium iron) was in good condition, so far as resistance to corrosion and cracking was concerned. By driving new staybolts, however, cracks occurred and it seemed evident that room temperature is not suitable for this operation. A temperature near the boiling point of water is recommended. Ha (29)

Measurements with the Aid of Liquid Helium. XII. Plasticity of Metal Crystals at the Lowest Temperatures. (Messungen mit Hilfe von flüssigem Helium. XII. Plastizität von Metallkristallen bei tiefsten Temperaturen). W. Meissner, M. Polanyi & E. Schmid. *Mitteilungen der deutschen Materialprüfungsanstalten*, Sonderheft 18, 1931, pages 30-34.

In Zn and Cd crystals there is not much difference in the stress for beginning of deformation between room temperature and 1.2° absolute (obtained with liquid He). At the very low temperatures the rate of application of load has little effect. Flow under such conditions is athermic, not affected by temperature. Flow of amorphous materials on the contrary is vastly affected by temperature. The partial distortion of the crystal structure occurring on deformation brings the plastic behavior of the crystal nearer to that of an amorphous body. Athermic deformation causes hardening, and this is opposed by thermal softening (crystal recovery or recrystallization). At medium temperatures the deformation curves depend on temperature and rate of loading. The apparatus and methods used for determining deformation curves at the temperature of liquid He are illustrated and described. HWG (29)

Tests of the "Creep" of Lead Cable Sheathing Under Steady Load. H. F. Moore. *Bulletin, Utilities Research Commission*, Vol. 2, Oct. 1931, pages 1, 3, 4.

Creep curves on Pb at room temperature have the same general form as high temperature creep curves for steel. Semi-log plotting of stress versus time for 1% creep indicate the existence of a creep limit at about 200 lbs./in.², with little variation between 32° and 150° F. The alloys of Pb with Sb or Sn creep less rapidly at higher stresses than pure Pb, but appear to have no higher creep limit. Tensile creep on specimens cut from cable sheath and expansion in diameter of sections of sheath under constant internal oil presure lead to similar results. HWG (29)

The Cold Treatment of Certain Alloy Steel. G. V. Luerssen & O. V. Greene (Carpenter Steel Co.). *American Society for Steel Treating, Preprint* No. 24, 1931, 44 pages.

Paper read and discussed before the Boston Convention of the Society in Sept. 1931. 12 references. 18 micrographs illustrate the structures studied. The paper points out certain "borderline" type of alloy steels between austenitic and martensitic or pearlitic which show appreciable hardening on cooling to low temperatures. Studies of 2 Cr-Ni, 2 Ni-Si steels and a 17½%Cr-5%Ni stainless steels are reported. The properties developed by such treatments are given. The great possibilities of such treatments are pointed out and the many advantages that may be secured in the properties of alloys susceptible to such treatment are discussed. WLC (29)

The Influence of Atmosphere and Temperature on the Behavior of Steel in Forging Furnaces. D. W. Murphy & W. E. Jominy. *Engineering Research Bulletin*, No. 21, *University of Michigan*, Oct. 1931, 148 pages.

When steel is heated prior to forging, the quality of the metal may be injured unless attention is paid to the control of the gases surrounding the metal and the temperature to which the steel is heated. In an oxidizing atmosphere produced by the use of excess air scale forms rapidly, and at high temperatures the steel is permanently injured by burning. In a reducing atmosphere, that is by firing with a deficiency of air, scale forms to a smaller extent and the burning temperature is raised. Heating plain C steels to temperatures near the burning point did not seem to affect any of the common physical properties associated with tensile tests when the steel was subsequently annealed or heat treated. The scaling increases with increasing time of exposure and temperature, and the scaling losses increase considerably with the presence of even small amounts of sulphur dioxide in the furnace gases. The sulphur content of the steel itself increases by absorption of sulphur from combustion gases carrying sulphur dioxide. The best fuels for forging furnaces should therefore be low in sulphur content. Fast rates of heating were not found to cause injurious temperature gradients in steel sections up to 4" square. The rate of heating is known to be in part a function of the composition of the gases, since the luminosity and hence the radiating power of a flame increases as the proportion of fuel to air increases. For details of test methods and test results the paper must be referred to. Ha (29)

High Temperature Characteristics of Metals Revealed by Bending. H. Scott. *Proceedings American Society for Testing Materials*, Vol. 31, Pt. 2, 1931, pages 129-156.

If a metal strip is held in a bent position, as by placing it in a curved slot, and heated, any plastic deformation under that strain and temperature will be manifested by residual curvature of the strip after cooling and removing from the slot. Devices for constraining the strip and measuring the residual curvature are described. The ratio of residual curvature to curvature of constraint is termed the "bending ratio." Plotting this against applied strain shows knees in the curves for cold rolled phosphor bronze strips having had different tempering treatments, which correspond to the proportional limits of the samples in tension tests, but indicate that there is plastic deformation below the proportional limit. At elevated temperatures, the degree of plastic deformation is greater. The knee is present at 140° C, scarcely recognizable at 180° C, and disappears above 200° C. The curves indicate that the phosphor bronze used may be loaded to around 2500 lbs./in.² at 100° C. or 900 lbs./in.² at 150° C. without plastic deformation but that at 200° C., plastic deformation will occur at any finite load. The degree of deformation shown by phosphor bronze, under given test conditions at 200° C., is reached in 80:20 nichrome at about 500° C. and in one of the age-hardened Konel Ni-Co-Ti alloys, composition not stated, at about 575° C. This bend test shows that the rate of plastic deformation increases markedly with the amount of previous cold rolling. The decrease in apparent modulus of elasticity at elevated temperatures is indicated to be largely due to initial set, which increases more rapidly with increasing temperature than does the rate of plastic deformation. This bend test is suggested as a supplement to the creep test for the study of flow of metals at high temperatures. HWG (29)

The Mechanism of Breakage of Steel. Part I. Masao Kuroda. *Rikagaku Kenkyusho Iho*, Vol. 10, Dec. 1931, pages 1085-1104.

By studying the stress-strain diagrams in tension of a very soft steel and noting the accompanying change of structure, the cause of a characteristic phenomenon in the yield point of steel was explained and the mechanism of change occurring from the yield point to the breaking point was proposed. At first, the relations between stress and strain in the tension tests at several temperatures from room temperature to 300° C. were studied. The discontinuities on the stress-strain curves are most marked at 200° C. Hence the changes of macro- and micro-structures in the several stages of breakage were observed intermittently. The tension tests were also carried out at room temperature under constant loads during which the macroscopic changes were observed and photographed. The mechanism of breakage was proposed under the following hypothesis: A mild steel consists of ferrite grains and cementite, the former being enveloped by a thin film of the latter. There exists a layer of solid solution of ferrite dissolving carbon in supersaturation; a brittle honey-comb structure with the cementite film being formed. This structure was termed by the author "boundary structure." From this hypothesis, the author proposed the following mechanism for breakage of steel: If the stress is applied to a mild steel composed of the ferrite and the boundary structure, the latter is cracked and broken down, when the stress is increased to the breaking point of the boundary structure, since this part is more brittle and weak than the ferrite. Lüder lines are thus formed by the cracking of part of the boundary structure and the stress at this point is the yield point. Since the ferrite resists the stress of the yield point, the remaining portion of the boundary structure is further cracked and the Lüder lines are further formed. When the boundary structure is wholly cracked by the stress of the yield point, the stress is increased, and the ferrite is deformed. The stress-strain curve above the yield point for mild steel is not similar to that of pure iron as the boundary structure can yet resist the shearing slip of the ferrite. The strength of the boundary structure is markedly affected by temperature. In the vicinity of 200° C., the structure is tough and strong, but at lower temperatures the structure is brittle. As the temperature increases, the viscosity of the boundary structure gradually decreases, and the discontinuity at the yield point decreases. This effect is most marked at about 200° C. and the discontinuity on the stress-strain curve, which is not observable at room temperature, markedly observable. TM (29)

Trends in Engineering Requirements for Metals for the Power-Plant Industry. H. J. Kerr (Babcock & Wilcox Company.). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee*, 1931, pages 15-29.

For abstract of paper see *Metals & Alloys*, Vol. 2, Oct. 1931, page 231. In the discussion it was emphasized that if temperatures and pressures in power plant engineering were raised to the ultimate limits which are now known they would not exceed 3000 lbs. gage and a final temperature of 1100° F. The specifications for the component parts of boilers as proposed by Kerr are therefore not only sufficient for present-day needs but for some time to come. The creep limit of 1% in 100,000 hours as set by Kerr for safe boiler design work could probably be quadrupled and still have an ample margin of safety. Welding and thermal conductivity in this field must not be overlooked if economical advances are to be made. It is suggested that veneered or coated metals might offer interesting possibilities as applied to some of the high strength alloys. Most of the discussers are of the opinion that a stress requirement of 10,000 lbs/in.^{2} at 1300° F. as set by Kerr is rather severe and too large an order for metallurgists at the present time. The only creep value recorded which is of this order is that by Tapsell and Renfry for steel containing 0.5% C, 27% Ni, 14% Cr and 4% W. A value of 13,440 lbs. at 1292° F. is given for this steel and this is probably not based on a creep rate of 1% in 100,000 hours. WAT (29)

Behavior of Materials at Low Temperatures with Special Reference to the Lignite Trade. (Das Verhalten von Materialen bei tiefen Temperaturen unter besonderer Berücksichtigung der Braunkohlenbetriebe.) E. Krieg. *Braunkohle*, Vol. 29, Oct. 18, 1930, pages 937-947; Oct. 25, 1930, pages 960-968.

Ferritic materials increase in brittleness at low temperatures. Ni-rich austenite does not. Soft Cu does not lose ductility or become brittle at -200° C. and hard-drawn Cu acts about the same as annealed Cu. Contraction may raise the loading to so high a value that Cu may fail, but this is not due to loss of ductility. Al becomes tougher at low temperatures. Pearlitic Ni steel (0.6% C 2.3% Ni) is still tough at -80° C., but brittle at -190°. The toughness is restored on reheating to room temperature. Ferronickels of 37 to 99% Ni have good notch toughness at -20° C. but very low at -80° C., but on further cooling to -190° much of the toughness is restored. 60:40 brass retains toughness all the way down to -190° C. The notch toughness of raw steel castings and of annealed and slow cooled castings is low at low temperature, but is improved by rapid cooling from the annealing temperature. Addition of Si to steel brings the change from tough to brittle material at higher temperatures. With 5% Si, brittleness appears at 300° C., with 3% Si, about 150° C. In general, heat treated (quenched or normalized and drawn) steels are superior in low-temperature toughness to annealed steels. Wire rope for bucket conveyors, etc. should not be of too high tensile strength, since steel of 285,000 lbs./in.^{2} is more brittle at low temperatures than that of 220,000. Various suggestions are given for preventing freezing of materials to be handled, by use of magnesium chloride, etc., for winter lubrication, and so on, to reduce the load put on equipment in winter use, so as to keep from applying heavy shock to material that may be in a brittle condition. Rail failures are ascribed largely to the inelastic condition of frozen ballast, so that drainage of the road bed is desirable to avoid its freezing to too solid a mass. Snapping off of rivet heads is common in cold weather and welding is preferable to riveting, but precautions have to be taken when welding in cold weather. HWG (29)

Corrosion and Other Problems in the Use of Metals at High Temperatures in the Chemical Industries. F. H. Rhodes (Cornell University). *Symposium on Effect of Temperature on Metals, A.S.T.M.-A.S.M.E. Joint Research Committee*, 1931, pages 100-111.

For abstract of paper see *Metals & Alloys*, Vol. 2, Nov. 1931, page 283. In the discussion the Calorizing Company states that microscopic examination of calorized tubes removed from converters of an eastern chemical company after two years service showed no signs of deterioration. The International Nickel Company reports that the longer life of pure Ni tubes in caustic evaporators over that obtained by steel tubes has justified their use and enabled the production of purer caustic. Another discusser presents data showing that low C steels having above 12% Cr are quite resistant to caustic attack and that additions of Ni to these alloys destroys the resistance offered by the Cr. WAT (29)

Secondary Effects on Hysteresis Hoops at Elevated Temperatures. (Über Nachwirkungserscheinungen an Hystereseschleifen bei höheren Temperaturen.) H. Kühlewein. *Physikalische Zeitschrift*, Vol. 32, Nov. 15, 1931, pages 860-864.

The present paper presented before the 7. Deutscher Physiker und Mathematikertag, Bad Elster, Sept. 1931, refers to tests on Fe, Ni, Fe-Ni alloys, and Fe-Ni-Co alloys in the γ range studied with the object of correlating the influence of rising temperatures to the remanence and coercive force. EF (29)

The Specific Heat of Tantalum, Tungsten, and Beryllium from 100° to 900° C. (Untersuchungen über die spezifischen Wärmen von Tantal, Wolfram, und Beryllium zwischen 100° und 900°C). A. Magnus & H. Holzmann. *Annalen der Physik*, 5th Series, Vol. 3, 1921, pages 585-613.

The atomic heat at constant pressure was found to be for Ta $6.1742 + 1.0093 \cdot 10^{-3}.t$ for W $5.8947 + 8.338 \cdot 10^{-4}.t$ for Be $3.5354 + 0.88033 \cdot 10^{-2}.t - 0.11738 \cdot 10^{-4}.t^2 + 0.61307 \cdot 10^{-8}.t^3$. A large Magnus Cu calorimeter was used and the precautions taken to get precise results are described, but the only details as to purity of the metals tested are the statements that the Fe "was the purest so far prepared," the W was "highest purity," and that Be was supposed to be 99.9% pure. HWG (29)

An Apparatus for Ballistic Ring Measurements at Elevated Temperatures. (Eine Apparatur für ballistische Ringmessungen bei höheren Temperaturen.) H. Kühlewein & H. Neumann. *Physikalische Zeitschrift*, Vol. 32, Sept. 15, 1931, pages 727-730.

A simple arrangement is described designed for accurate ballistic ring measurements on magnetic materials at elevated temperatures up to the Curie Point. The practical utilization of the equipment is demonstrated by a set of experiments with charcoal iron. EF (29)

Mechanical Properties of Low Alloy Cast Steel at Elevated Temperatures. (Mechanische Eigenschaften von niedriglegiertem Stahlguss bei erhöhten Temperaturen). F. Körber & A. Pomp. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 13, 1931, pages 223-236; *Stahl und Eisen*, Vol. 52, Jan. 14, 1932, page 46.

15 alloy cast steels, made in an electric furnace, were tested at room temperature, 300°, 400° and 500° C. The type composition of the steels tested varied as follows: 2 plain C steels, 0.22-0.35% C, 1.15-1.80% Mn; 2 C-W steels, 0.27-0.32% C, 0.87-0.93% W; 2 C-V steels, 0.20-0.31% C, 0.28% V; 4 C-Mo steels, 0.21-0.40% C, 0.50-0.58% Mo, 0.46-1.03% Mn; 2 Cr-Ni steels, 0.20-0.28% C, 0.52-0.56% Cr, 1.06-1.50% Ni; a steel containing 0.17% C, 1.06% Cr and 0.51% Mo; a steel containing 0.28% C, 2.52% Ni and 0.40% Mo; and a steel containing 0.33% C, 0.66% Cr, 1.86% Ni and 0.36% Mo. Yield point, tensile strength, elongation, reduction of area, modulus of elasticity and notch toughness were determined. It is shown that the Ni-Mo steels with or without Cr are superior to all other steels. Also that the Mo steels without Ni but with contents of Cr and Mn show better properties than those without Mo. The same holds true for the high Mn steel. The straight Cr, Ni, W, and V steels are inferior to the other alloy steels tested. GN (29)

Influence of Temperature on the Toughness of Aluminum Alloys. T. Kobayashi. *Memoirs Ryojun College of Engineering*, Vol. 3, No. 2 A, May 1930, pages 145-153.

The variations with temperature of the toughness of a number of commercially important Al alloys has been determined by an impact method for the interval 20° to 550° C.

Scaling of Steel at Elevated Temperatures by Reaction with Gases and the Properties of the Resulting Oxides. D. W. Murphy, W. P. Wood & W. E. Jominy. *Transactions American Society for Steel Treating*, Vol. 19, Jan. 1932, pages 193-232.

Includes discussion. See *Metals & Alloys*, Vol. 2, Nov. 1931, page 284. WLC (29)

Mechanical and Creep Properties of Molybdenum Cast Iron. C. H. Lorig & F. B. Dahle (Battelle Memorial Institute). *Metals & Alloys*, Vol. 3, Oct. 1931, pages 229-235.

20 references. The authors report a study of the mechanical properties of cast iron with Mo content up to about 1.50%. Curves and data presented show that this amount produces the maximum benefit to the mechanical properties, hardness, tensile and transverse properties at room and elevated temperatures. The properties at elevated temperatures merit consideration of this alloy. WLC (29)

Power Station Temperatures and Tensile Strength. *Metal Industry*, London, Vol. 38, June 19, 1931, pages 617-618.

Pressures up to 3,200 lbs./in.^{2} are considered possible. The usual temperature limit is around 800° C. Hecla/ATV is the alloy adopted for turbine blades, having shown no corrosion after 7 yrs. Non-ferrous metals are used for steam fittings.

The Thermal Expansion of Some Aluminum Alloys. E. E. McCollough. *Physics*, Vol. 1, 1931, pages 334-339.

Determinations of the thermal expansion coefficients of the following metals and alloys from 25°-100° C., pure Al, pure Mg, commercial Al, electrolytic Cu and alloys of Al-Fe, Al-Mn, Al-Si, Al-Ni, Al-Cu, Al-Mg and Al-Cu Si-Mn. All the alloying elements investigated have an effect on the thermal expansion of Al. An empirical equation based upon the assumption that the coefficient of thermal expansion of the alloy is the arithmetical mean of the coefficients of expansion of Al and the alloying element, is limited in its use. The thermal expansion data for the Al-Cu alloys (2.3-9.4% Cu) indicate a maximum coefficient at about 8% Cu. The data for the Al-Mg alloys (1.5-15% Mg) indicate a minimum coefficient at about 2% Mg content and alloys containing more than 8% Mg have greater coefficients of thermal expansion than that of Al. The Al-Fe alloys (2.5-11% Fe) show a decrease in expansion with increase of Fe content. The Al-Ni alloys (3.8% Ni) show a decrease in rate of expansion with increasing amounts of Ni. The Al-Si alloys (4-16%) also show decrease with increasing Si. The Al-Mn alloys (0.5-1.5% Mn) show that at 1.5% Mn the expansion is less than it is at 0.5-1% Mn. For the Al-Cu-Si-Mn alloys, no general relations were found between the percentages of the alloying elements and the corresponding coefficients of thermal expansion. WAT (29)

The Range of Brittleness of Iron at Low Temperatures. (Ueber den Sprödigkeitsbereich von Eisen bei tiefen Temperaturen.) F. Sauerwald, B. Schmidt & G. Kramer. *Zeitschrift für Physik*, Vol. 67, No. 3/4, 1931, pages 179-183.

The breaking strength of Fe is studied as a function of the temperature. Technically soft Fe is found to become suddenly brittle at -155° C. and its dilatation small. This critical temperature rises to -90° C. for single crystals.

The Rapid Determination of "Creep" Strength. *Metallurgist*, Apr. 1931, pages 56-59.

A critical review of 7 references. VVK (29)

Torsional Modulus of Spring Materials Affected by Temperature. F. P. Zimmerli, W. P. Wood & G. D. Wilson. *Metal Stampings*, Vol. 4, June 1931, page 492.

Silal Heat Resisting Cast Iron. *Bulletin of the British Cast Iron Research Association*, Vol. 3, Oct. 1931, pages 35-37.

Silal is a cast iron that does not grow and is scale-resisting and shows its best mechanical properties at temperatures from 700° to 900° C. It has a tensile strength of 5000 lbs./in.^{2} at 800° C. with 1½% elongation. The report shows very satisfactory results in furnace castings and locomotive fire bars. Ha (29)

Smelting in the Lead Blast Furnace, Handling Rich Charges. I. Conditions at the Tuyère Zone. *U. S. Bureau of Mines Report of Investigations* 3096, Apr. 1931, 21 pages.

Air flow per tuyère was 130 to 600 ft.^{3}/min. except for openings entirely closed. The flow through any tuyère varied less than 10% over ½ hour periods, but several 100% for different days. From 25 to 60% of the cross sectional area at the tuyère zone was open enough to permit molten charge to flow freely. The material surrounding the free zone was semi-plastic and differed but little from the rest of the charge in composition. The shape and size of the free-smelting area changed rapidly. A narrow and elongated free-smelting zone at the tuyères near the center of the furnace gave the maximum capacity in smelting; about 25% of the total area is free of semi-plastic solids. The slag temperatures when tapped were 1070-1080° C; the Pb in the crucible 870-1010° C. As the capacity of the furnace increased, the bullion was hotter and the slag colder. Charging coke separately instead of admixed with other ingredients gave better reduction of the Pb compounds, but colder bullion and hotter slag. When the furnace ran at high capacity the smelting occurred higher up in the shaft and the molten Pb was longer in contact with hot slag. When the smelting zone was more localized at the tuyères and spread over a larger area, more complete reduction of Pb compounds ensued, the slag was melted lower in the shaft and the molten Pb had less opportunity to become hot. The air in the blast did not react until it reached the free-smelting zone. The zone of highly reducing gases was very narrow and the transition was often abrupt. Temperatures were low in the plastic zone and high in the intensely reducing zone, up to a maximum of 1400° C. With a given sinter, the loss of Pb in the slag increases with an increase in the rate of smelting charges beyond a certain point. The form of combination of the Pb in the molten charge was also a function of the time allowed for reduction. Chilled material from the tuyères in the center of the furnace past which the molten material would probably flow at a maximum rate for mechanical reasons, showed the most Pb silicate and PbS. The ratio of each of the main slag-forming ingredients in the chilled materials taken from each tuyère was fairly constant. The discarded slags contain a large part of their Pb as sulphide. Sulphides are one of the major causes for the formation of accretions, lessen the capacity of the furnace, necessitate the consumption of extra coke and scrap Fe, when in the bullion make more secondaries to be handled, and result in Pb losses in the slag. AHE (31)

Tendencies in Blast Furnace Practice. Fred. Clements. *Iron & Steel Industry & British Foundryman*, Vol. 5, Dec. 1931, pages 67-73.

The general principles of pig Fe production and their connection with practice as dictated by the economic situation in a given locality are considered. Modern trends in the preparation of ore, the fluxes used, the grading requirements in fuel, temperature control and drying of the air blast, change in the lines of furnaces, charging and distributing gear, utilization of higher quality refractories and the handling of the furnace products are discussed. CHL (31)

Modern American Metallurgical Practice. W. D. Jones. *Chemical Engineering & Mining Review*, Vol. 24, Oct. 5, 1931, pages 11-14.

An abstract of a report read before the Institution of Mining & Metallurgy, London, covering the inspection of 20 metallurgical plants in America. Pb, Cu, Zn, Fe and auxiliary and miscellaneous plants were included. See also *Metals & Alloys*, Vol. 2, Dec. 1931, page 326. WHB (31)

Smelting Secondary Aluminum and Aluminum Alloys. Robert J. Anderson. *Metal Industry*, New York, Vol. 29, Nov. 29, 1931, pages 474-476; Dec. 1931, pages 519-520.

Part 11—Metal Recoveries in Secondary Aluminum Practice. It is preferable to sell scrap on a recovery basis. The effect of the general character of the scrap, such as weight and cleanliness, of pre-treatment, such as sorting, magnetizing, cleaning, grinding, etc., and of melting and the furnace technique are all discussed in a general way. *Part 12—Recoveries secured in practice on different kinds of scrap.* Tables listing recoveries based on total weight of material handled are given on carload shipments of some kinds of drosses and on re-melting various kinds of Al and Al alloy scraps. PRK (31)

A Graphical Method for Determining the Degree of Oxidation of Fe Ores (En grafisk method för beräkning av järnmalmers oxidationsgrad). I. Sahlin. *Jernkontorets Annaler*, Vol. 115, Sept. 1931, pages 484-486.

A graph is constructed from which the degree of oxidation of Fe ores may be read directly when the percentages of the various oxides present are known. HCD (31)

Smelting in the Lead Blast Furnace. Handling Rich Charges. VIII. The Gases From the Top of the Furnace. *U. S. Bureau of Mines Report of Investigations* 3095, Apr. 1931, 19 pages.

The composition of gas issuing from the top of the charge in the Pb blast furnaces at Kellogg, Id., varied greatly, - O_2 from a few tenths to 20%, CO up to 15%, CO_2 10-28% and usually 20-28%, and H_2 up to 0.5%. Temperatures were 100-1100° C. There was a general tendency for the gas to be a little richer in CO in areas near the slag tap. In operating at forced capacity (coke 10-12%), maximum CO and maximum temperatures were higher above the tuyères than at Tooele. Change from oxidizing to reducing conditions was very rapid. The furnace acted both as a blast roaster to oxidize sulphides and to reduce Pb compounds to metal. From 10 to 12 tons of dust/furnace/day was made. The major constituents were volatilized products, chiefly Pb, with lesser Cd and Zn. Fe oxides, CaO and insolubles were small in amount. The gases are diluted 6 or 7 parts to 1 by the time they reach the bag house (for cooling purposes). AHE (31)

Some Recent Developments in the Mechanical Charging of Blast Furnaces. Geo. B. Garrett. *Iron & Steel Industry & British Foundryman*, Vol. 5, Dec. 1931, pages 105-108.

American practice in the mechanical charging of a blast furnace is given. CHL (31)

Purification of Zinc Ores in Sintering. Reed H. Hyde. *Mining & Metallurgy*, Vol. 12, Sept. 1931, pages 410-411.

Sintering methods which drive off the Pb and Cd from the Zn ores so that a purer Zn metal or oxide is obtained are briefly described. Ha (31)

Manufacture of Ferro-Silicon. Roy P. Hudson. *Blast Furnace & Steel Plant*, Vol. 19, Mar. 1931, pages 399-401.

The manufacture of ferro-Si in the blast furnace as a regular product is explained; its uses and the properties of alumina slags are briefly discussed. Ha (31)

Gas and Stock Flow in the Blast Furnace. S. P. Kinney. *Blast Furnace & Steel Plant*, Vol. 19, Mar. 1931, pages 407-411.

The distribution of gas velocities from wall to center of the blast furnace is illustrated in charts and diagrams and some of the irregularities found in blast furnace practice are discussed. Ha (31)

Dezincification of Lead Slags. (Zur Entzinkung von Bleischlacken.) Thews. *Die Metallbörse*, Vol. 21, Feb. 21, 1931, pages 339-340; Mar. 7, 1931, page 346.

The method of Pape, the Wälz process, the dezincifying in the blast furnace, the liberation of Zn by blowing compressed air into the liquid slag (Anaconda method versus German Patent 232,479) and the author's own experiments are covered. EF (31)

Reduction of Chromium Oxide and Production of Carbon-free Chromium-Iron Alloys. (Beitrag zur Reduktion des Chromoxyds und zur Darstellung kohlenstoffreier Chrom-Eisen- Legierungen.) H. H. Meyer. *Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 13, Report 187, 1931, pages 199-204; *Stahl und Eisen*, Vol. 51, Dec. 17, 1931, pages 1574-1575.

The investigation reported continues a former investigation on the reduction of MnO, SiO_2 and P_2O_5 (*Mitteilungen Kaiser Wilhelm Institut für Eisenforschung*, Vol. 9, 1927, pages 273-277.) Cr_2O_3 in the absence of Fe is not reduced by hydrogen below 1600° C. Mixtures of Cr_2O_3 and carbonyl-Fe containing 0.02% C and 10-50% Cr_2O_3 were reduced by H at 1150-1400° C. The reduction begins at 1150° C.; at 1350° C. 95% reduction is attained after 11 hrs.; the alloy formed contained 13.03% Cr. An alloy containing 19.1% Cr was obtained from a mixture containing 35% Cr_2O_3 reduced for 11.5 hrs. at 1350° C. and giving 79.8%. No clear relation could be found between the amount of Cr_2O_3 in the mixture and the velocity of reduction. In spite of the variable C content of the specimens and the variable time and temperature of reduction the alloy obtained always contained 0.04-0.06% C and the reduction was not accelerated by C. For Cr plating it is necessary to use temperatures at which the Cr_2O_3 sinters; since the oxide then is not in close contact with the parts to be plated the plating is not uniform but spotty, causing an accelerated corrosion. This can be avoided if parts are plated repeatedly. Pieces of electrolytic Fe, Krupp soft Fe and a steel with 0.77% Cr were thus plated without difficulty, although there was a pronounced tendency for intercrystalline corrosion. The Herbert pendulum hardness of the Cr-plated electrolytic Fe was uniform and not much harder than electrolytic Fe. In the Krupp soft Fe, and still more in the 0.77% C steel, fluctuations of the hardness occurred due to the formation of carbides. Some spots were 145% harder. When the Cr-plated specimens are heated to 1150° C. in H and then quenched in H_2O the specimens possess, independent of the C content, a hardness which is uniform throughout the surface. This is due to the formation of martensite. The quenched Cr layer is hardly attacked by HNO_3. Lamellar pearlite occurring along the grain boundaries and near the surface of Cr-plated specimens, particularly in the electrolytic Fe, causes intercrystalline corrosion. The pearlite disappears when the specimens are annealed at 1200° to 1250° C. for 1-3 hrs. The formation of the pearlite is due to the fact that the Cr content of the outer Cr layer is so high that the γ-field is not passed, but an annealing above 1100° C. equalizes the Cr content of the Cr layer and the whole layer then passes the γ-field in cooling. Thus pearlite is not formed but a martensitic structure appears. 9 references. GN (31)

Course of the Reactions in Bosh and Hearth of Blast Furnaces and Its Meaning for the Blast Furnace Process. (Verlauf der Vorgänge in der Rast und im Gestell und ihre Bedeutung für den Hochofenprozes.) A. Mund, J. Stoecker & W. Eilender. *Stahl und Eisen*, Vol. 51, Nov. 26, 1931, pages 1449-1462.

Report 124 of the Blast Furnace Committee of the Verein deutscher Eisenhüttenleute. Reactions in a 500 ton blast furnace running on "steel Fe," "hematite" and foundry pig Fe were investigated. Since the bosh of the furnace is about 5 m. high and the hearth is rather narrow, 3.9 m., the furnace is equipped with a group of additional tuyères 1825 mm. above the main tuyères. About 600 samples were drawn from the 2 levels of the tuyères and from the cinder notch. A special apparatus was devised for taking samples from the center of the bosh. Part of the liquid pig Fe oxidizes in front of the tuyères, to be later reduced below the main tuyères. To effect this reduction, the accompanying elements in the pig Fe are not sufficient, for the greatest part of them are not introduced into the Fe until the hearth is reached. Reduction of some of the burden and of the burnt Fe, desulphurization and slagging of the ash of the coke is effected in the hearth. GN (31)

Particle Size of Charges in Swedish Charcoal Furnaces. (Beskickningens styckestorlek vid svenska träkolsmasugnar.) Ivar Bohm. *Jernkontorets Annaler*, Vol. 116, Jan. 1932, pages 19-38.

The percentages of material above 18.85 mm. were 67.1, 39.1, 64.8, 6.2, and 56.3 in the 5 furnaces studied; less than 1.16 mm. were 14.2, 28.4, 4.8, 36.8, and 10.0; and less than 0.074 mm. were 2.4, 6.7, 0.8, 6.6, and 1.5. Marked individual variations were noted as the charging hoppers were emptied and refilled during a run. HCD (31)

NON-METALLIC COATINGS FOR METALS & ALLOYS (32)

Metal Finishing. *Electrician*, Vol. 107, Oct. 2, 1931, page 476.

"Bonderite" is a concentrated chemical in powder form which, when dissolved in boiling water, forms a solution that reacts quickly upon immersed iron or steel, converting the surface to a non-metallic coating that is part of the metal. Only incidental cleaning is necessary and Bonderizing is accomplished in a heated tank. 8-12 minutes' immersion in the solution is sufficient. Parkerizing is also employed at the plant of the Pyrene Co., Ltd., Great West Road, Prestford, Middlesex. WHB (32)

Acid Proofing Tanks. *Engineering & Mining Journal*, Vol. 132, Sept. 28, 1931, page 270.

The Kobbe Laboratories, Inc., N. Y. have developed a compound known as Vitrobond for proofing acid tanks. It is a S-base compound that is impervious to hot or cold acid. It has a tensile strength many times that of S, is unaffected by heat and exceptional in adhesive properties. WHB (32)

Asphalt Emulsion as Protective Coating for Metal Surfaces. *American Metal Market*, Vol. 38, Apr. 25, 1931, page 3.

The du Pont laboratory tests show asphalt emulsion having all inherent characteristics of basic asphalt or pitch, but which does not flow under heat, for use in cable and electrical apparatus trade. DTR (32)

Cleaning and Enameling Metal Surfaces. E. F. Werner. *Metal Cleaning & Finishing*, Vol. 3, Mar. 1931, pages 237-239.

A detailed outline of the cleaning and enameling process as used in the plant of a large manufacturer is given. It includes a description of the cleaning and enameling equipment. Ha (32)

Protecting Steel Pipe Lines with Thin Concrete Covering. *Engineering News-Record*, Vol. 106, May 14, 1931, page 817.

Bituminous and wrapped coverings are the usual protective measures. In certain limited sections, where alkaline and other corrosive action is pronounced, concrete, crudely applied and expensive, has given satisfaction. (32)

Modern Method of Spraying Paints and Varnishes. (Neuzeitliche Farb- und Lackspritzverfahren.) H. Reininger. *Maschinenbau*, Vol. 10, Jan. 1, 1931, pages 9-11.

The article gives a critical comparison of the spraying and dipping processes with the brush method, for coating metals. The advantages of the two former are outlined. MAB (32)

Protective Coatings for Pipe Lines. *Chemical & Metallurgical Engineering*, Vol. 38, July 1931, page 402.

A desirable coating for storage protection of pipe consists of 10% zinc chromate and 90% oil base, ¾ of which is tung oil and the remainder oils processed under heat. PRK (32)

Asphalt Coating Protects pipeline Against Texas Soil Corrosion. *National Petroleum News*, Vol. 22, Apr. 23, 1930, pages 57-58.

A 2" coating of asphalt is being used by the Houston Pipe Line Co. for protecting pipe in the swamp areas of the coastal plains region. A galvanized iron form is used in the application of the coating. VVK (32)

Unique Type Conveyor Developed for Oven Installation. *Fuels & Furnaces*, Vol. 8, Sept. 1930, pages 1263-1268; *Metal Cleaning & Finishing*, Vol. 2, Oct. 1930, pages 891-896.

Illustrated description of an installation of ovens and accessory equipment for finishing of metal furniture. Consists of wash tanks, dry-off oven, dip tanks and primer bake-oven served by a continuous conveyer which combines the desirable features of both the cross-bar and the monorail types of conveyors and also grain-coat and lacquer ovens. MS (32)

Rubber Tank Linings in Steel Pickling Operations. *Rubber Age*, Vol. 30, Oct. 10, 1931, pages 21-22.

A new principle, the Vulcalock process, embodies a new method of vulcanization, whereby soft elastic rubber can be attached directly to the surface of metals with an adhesion exceeding 500 lbs./in.^{2} It makes practically an integral union. This method eliminates the unsatisfactory service given by soft or hard rubber linings for pickling tanks through the physical damage of the former and great difference in expansion at extreme temperature changes for the latter. The hard rubber layers are, in the new process, not joined together but overlap each other and are bound together by soft rubber which absorbs the expansion and contraction and eliminates buckling and cracking. Considering that life is longer than in the case of wood, especially at temperatures above 100° F., the costs are practically the same. Ha (32)

Formation of Spots on Metal Wares Coated with Zapon Lacquer (Fleckbildung auf zaponierten Metalwaren). Freitag. *Oberflächentechnik*, Vol. 8, Oct. 20, 1931, page 217.

The brown spots marring the appearance of zaponized articles can be suppressed by adding certain collodion preparations, cyclohexanol, to the lac and using ethylglycol as a solvent. The reason for this phenomenon is not quite clear. Ha (32)

Reconditioning Lines Costs Millions. E. P. Bly (Standard Oil Co. of California). *Oil & Gas Journal*, Vol. 29, June 5, 1930, pages T-36, T-40.

2 general plans for laying out reconditioning (pipe line) plans are discussed. One is to do the work soon enough so that substantially no leaks or pipe repairing are involved and the second is to wait until "tell-tale" pit holes actually occur—and others become imminent. In the first case, long stretches of pipe have to be worked over so as to be quite sure all incipient bad spots are discovered. Much unnecessary work is done, but the average cost per ft. is, of course, lower than when pipe repairs have to be contended with. When the unconditional avoidance of pit hole leaks is essential, this method is definitely required. In case 2, where actual pit hole occurrence is the criterion for reconditioning, the work can be confined to relatively short stretches (sometimes called "hot spots") and although the cost/ft. may be considerably higher, the total annual cost may show a substantial saving. When work is confined to "hot spots," in this way it sometimes becomes most expedient and economical to follow a complete replacement schedule rather than to make repairs and apply protective coatings under the unsatisfactory conditions which frequently prevail in the field. VVK (32)

Development of Pipe Coating Machines. Dozier Finley (The Paraffine Companies, Inc., San Francisco). *Oil & Gas Journal*, Vol. 29, June 5, 1930, pages T-119, T-122.

Representative types of pipe coating machines are described. VVK (32)

Painting and Maintenance of Elevated Tanks and Standpipes. James E. Gibson, et al. *Journal American Water Works Association*, Vol. 22, Oct. 1930, pages 1330-1342.

Superintendents' Round Table discussion. Red lead with linseed oil for rust protection followed by a coat possibly of aluminum paint to protect the red lead coat mechanically is generally recommended. Litharge is sometimes added to the red lead to produce quicker drying and to increase resistance to softening. Cement-lining can also be recommended. VVK (32)

Coating for Pipes. *American Gas Journal*, Vol. 135, Nov. 1931, pages 38-39.

Report of American Gas Association subcommittee. The conclusions reached were based on a set of A.G.A. specimens of coatings buried for about 9 mos., some specimens buried by the Bureau of Standards and removed after 6 yrs. and a few specimens buried by the United Gas Improvement Co. and removed after 17 yrs. Most of the data was based upon the first set of specimens which were buried only a short while, the conclusions reached are therefore only tentative and are subject to revision. No specimens of the A.G.A. test have been removed from alkali soils. The conclusions given were: 1. Coatings which develop numerous pinholes after a short period of burial are usually thin. They show some protective value in well drained soils for a limited time but are practically useless in poorly drained soils. 2. Coatings, which show a limited number or no pinholes after a short period of burial are usually thick and offer better protection than the thin coatings. 3. Thick coatings develop pinholes principally because of the mechanical effect of the soil on the coatings where the soil has the greatest mechanical action on the coating. 4. The organic reinforcing materials are decomposed to a greater or less extent by bacteria and fungi in the soil. The extent of rotting of these materials depends upon the nature of the soil and the extent to which they are protected with bitumens or disinfectants. 5. Unvulcanized rubber appears to be unsuitable for pipe coatings because it suffers plastic flow. 6. The pinhole test appears to be the best method for determining the condition of coatings in this test. The conductance of the coating after it is dry is a rough qualitative way of measuring the condition. 7. It is difficult to determine the relative merits of pipe coatings by means of visual inspection unless the ratings describing the separate effects of the exposure of the coating are combined into a single quantity. The chief weakness of any rating scheme is the difficulty of assigning proper numerical weights or values to the several factors entering into the rating scheme. CBJ (32)

Application of Finishes on Sheet Metal with Use of the Roller Coating Machine. H. W. Parmele. *Metal Cleaning & Finishing*, Vol. 3, Jan. 1931, pages 63-68.

The principle of applying finishing materials to sheet metal with the roller coating machine is explained. It is a rapid and economical procedure as the machine can be operated at high speed and the waste of the finishing material greatly reduced. Operation of the machine, kind of finishing material to be used and the importance of cleaning the sheets prior to coating is discussed. Ha (32)

Testing and Evaluation of the Behavior of Coatings Towards Water (Prüfung und Beurteilung der Wasserfestigkeit von Anstrichen). H. Wolff. *Korrosion und Metallschutz*, Vol. 7, Aug. 1931, pages 191-195.

"Water resistivity" involves 2 properties, according to the speaker at the General Meeting of the Reichsausschuss für Metallschutz, Kiel: (1) the resistance to the permeability of water tending to corrode the metal beneath; (2) the resistance to being destroyed by the water due to soaking and swelling up. The author outlines his experiments which largely pertain to an investigation of a paraffine emulsion, called "Enkaustin." EF (32)

Crystal Lacquer—A New Metal Finisher. Ray C. Martin. *Metal Cleaning & Finishing*, Vol. 3, Apr. 1931, pages 323-324.

This is a nitrocellulose lacquer and can give crackle, stipple and similar finishes. Ha (32)

New Lacquer Developments. S. P. Wilson. *Metal Cleaning & Finishing*, Vol. 3, Jan. 1931, pages 49-52.

A general discussion of nitrocellulose lacquers and their properties. Ha (32)

Modernizing Oven Equipment Leads to Cost Reductions. Phil. Kriegel. *Iron Age*, Vol. 128, Oct. 29, 1931, pages 1108-1113.

Modern production facilities for ovens for drying and baking enameled, japanned and painted metal parts are described. Arrangement of automatic conveyors will result in continuous processing, speeding up production and reducing labor, floor space and heat requirements. The article describes specific examples. Protection by Non-Metallic Coatings. (Schutz durch nichtmetallische Ueberzüge,—Farben, Lacke, usw.) W. Krumbhaar. *Paper before the First Corrosion Congress of the Verein deutscher Ingenieure, Verein deutscher Eisenhüttenleute, Deutsche Gesellschaft für Metallkunde, Verein deutscher Chemiker*, Oct. 20, 1931, Berlin.

The paper deals with the properties and testing of protective paints, lacquers, etc., against corrosion. GN (32)

Protective Paint Coatings on Refrigerator Pipes (Schutzanstriche für Rohrleitungen von Kühlmaschinen). W. Stumm. *Gas und Wasserfach*, Vol. 74, Sept. 12, 1931, page 866.

Briefly reviews the various coatings on the market and refers to the rust-protection materials Tornesit and Herolith, recently developed by the Mannesmannröhren Werke, Düsseldorf. EF (32)

Finishing Sheet Metal. H. M. Hagy. *Metal Cleaning & Finishing*, Vol. 3, Feb. 1931, pages 145-147.

The methods of producing satin, stipple, crackle, prismatic and shrivel finishes are explained. Ha (32)

Attaching Rubber to Metal Surfaces. Morris A. Hall. *Canadian Foundryman*, Vol. 22, Nov. 1931, page 12.

A very brief description, accompanied by 1 diagram, of a method whereby rubber sheet was attached to metal. OWE (32)

CONCENTRATION (33)

Classification (33a)

Some Local Metallurgical Considerations. Andrew King. *Journal Chemical, Metallurgical & Mining Society of South Africa,* Vol. 32, Sept. 1931, pages 34-44.

Presidential address before the society. Recent experimental studies of the extraction of Au from the picking belt wastes and recent developments in tube-mill grinding are described. AHE (33a)

Flotation (33c)

Milling Methods at the Questa Concentrator of the Molybdenum Corporation of America, Questa, New Mexico. J. B. Carman. *Information Circular* No. 6551, *United States Bureau of Mines,* Jan. 1932, 14 pages.

A granodiorite ore containing 4.5-7.5% molybdenite is treated by flotation at a cost of \$2.69/ton* of ore treated (Feb. 1 - Nov. 30, 1930). Pensacola No. 100 pine oil is the collector, G. N. S. No. 5 pine oil the frother and NaCN the pyrite depressor. One pound of a mixture of 5 parts Pensacola to 1 part G. N. S. pine oil (by volume) per ton of ore is added to the ball mill and 0.08 lb. NaCN (in a 10% solution) at the secondary cleaner. In the rougher cell, heads (not including returned middlings) average 5.2% MoS_2, concentrates 30%, and tailings 0.9%; in the primary cleaner, concentrates are 55% MoS_2 and middlings 4.0%; in the secondary cleaner, concentrates are 74.5% and middlings 7.0% MoS_2; recovery in the final concentrates is 87.7% MoS_2. AHE (33c)

Concentration of Copper Ore from Arno Mines, Ltd., Coxheath, Nova Scotia. G. B. O'Malley. *Canada Department of Mines, Mines Branch, Report* No. 720, 1931, pages 82-83.

Massive chalcopyrite with pyrite in a siliceous gangue analyzed Cu 4.89-5.54%, Fe 8.63-6.16%, S 8.62%, insoluble 77.98-61.92%, Au 0.01-0.03 oz. and Ag 0.72-0.52 oz./ton. Characteristic of flotation results with various reagent combinations were recoveries of 94.4% Cu, 81% Au and 72.8% Ag in a concentrate assaying 26.4% Cu, 0.04 oz. Au and 3.44 oz. Ag per ton with soda ash 5.0 lb., NaCN 0.15 lb. and thiocarbonalide 0.1 lb./ton in the ball mill and pine oil 0.06 lb./ton in the cell. AHE (33c)

Milling Methods at the Midvale Concentrator of the U. S. Smelting, Refining and Mining Co., Midvale, Utah. R. A. Pallanch. *Information Circular* No. 6492, *United States Bureau of Mines,* Aug. 1931, 17 pages.

The main ore supply contains 10-12% galena, 12-14% sphalerite, 25-30% pyrite, and the rest gangue, principally quartzite. Flotation is used. Reagents are: Pb circuit, (1) Zn depression—Na_2SO_3 and $ZnSO_4$, (2) Pb promotion—K xanthate, Republic 19 B oil, and cresylic acid; Zn circuit—$CuSO_4$, Republic 19 B oil, Yarmor steam-distilled pine oil, K xanthate and hardwood creosote; pyrite circuit—fused Na_2S. AHE (33c)

Electricity in the New Flotation Plant. H. B. Tinling (Tinling & Rowell). *Electrical West,* Vol. 67, Dec. 1, 1931, pages 298-300.

Electrical equipment installed in the flotation plant of the Jack Waite Mining Co. at Duthie, Idaho, is described. MS (33c)

Amulet Flotation Mill Practice. W. G. Hubler. *Canadian Mining & Metallurgy Bulletin* No. 226, Feb. 1931, pages 295-306; *Bulletin* No. 234, Oct. 1931, pages 1216-1219.

A detailed description is given of the flow sheet used at the Amulet mill, Canada, for the treatment of an ore assaying Au 0.02 oz., Ag. 3.5 oz., Cu 3.5%, Zn 13%, Fe 20%, and insoluble 36%. By flotation, a 24% Cu concentrate with a 92% recovery, a 52% Zn concentrate with an 80% recovery, and 75% recovery of Au and Ag were obtained. In the grinding circuit 0.5-0.8 lb. lime, 0.05-0.06 lb. cyanide, 0.05-0.07 lb. thiocarbonalide, 0.06 lb. Na_2S and 0.10 lb. pine oil were added per ton of total mill feed. To the Cu circuit, 0.03-0.08 lb. Na ethyl xanthate is added. The Cu tailings go to the Zn flotation circuit; Zn is floated using 1.3 lb. $CuSO_4$, 0.36 lb. water-gas-tar, 1.5 lb. lime, 0.08 lb. cyanide, 0.05 lb. pine oil and 0.06-0.10 lb. Na xanthate. AHE (33c)

Changing Over from Acid to Alkaline Circuit in Flotation Practice at the Mill of the Zinc Corporation, Limited, Broken Hill, New South Wales, Australia. Ralph D. Nevett. *Proceedings Australasian Institute of Mining and Metallurgy* No. 79, Sept. 30, 1930, pages 343-353; No. 80, Dec. 31, 1930, pages 445-460.

The Zn Corp. ore consists mainly of galena, marmatite, calcite and quartz with smaller quantities of pyrite, fluorspar and rhodonite. Aerocyanide is added to the slime feed at the conditioner and after 6 minutes run to No. 2 flotation cell where Vallo C oil and K xanthate are added. Float from cells 7-11 is returned to cell 1. The finished Pb concentrate is taken from cells 1-6. At cell 12 eucalyptus oil and K xanthate are added. The float from cells 12-14, which is too rich in Zn to return to cell 1, is run to a Wilfley table where a high-grade Pb concentrate is made. The bulk concentrate for the first number assayed Pb 75.7 and Zn 3.6%; tailings assayed Pb 0.9 and Zn 11%. Flotation tailings go to a 10-cell flotation machine. $CuSO_4$, Na aerofloat and eucalyptus oil are added, and a rougher concentrate of 30-40% Zn is obtained. Final tailings assayed Pb 0.2 and Zn 0.8%. The concentrate and Wilfley table tailings (reground and deleaded) are conditioned with CaO, fed to cell 4 with $CuSO_4$, Na aerofloat and eucalyptus oil, the float from cells 4-12 is returned to cell 1, and a Zn concentrate drawn from cells 1-3. The concentrate assayed Zn 51, Fe 8.9, Pb 2.1 and insolubles 1.7% with tailings assaying 1.2% Zn. AHE (33c)

Some Aspects of Ore Dressing. A. L. Engel. *Mining & Metallurgy,* Vol. 12, Oct. 1931, pages 447-449.

General observations on the conduct of daily operations in the plant, flotation process, air control, testing and main- Ha (33c)

Milling Methods and Costs at the Superior Concentrator of the Engels Copper Mining Co., Plumas County, Calif. V. I. Nelson. Information Circular No. 6550, *United States Bureau of Mines,* Jan. 1932, 22 pages.

A chalcopyrite-bornite ore (3:2), averaging 1.524% Cu, 0.345 oz. Ag and \$0.11 Au in 1929, is treated in 3 Minerals Separation flotation machines which produce finished concentrates (29.18% Cu), 3 middling products of different grades (13.42, 3.13 and 1.92% Cu, respectively) and tailings (0.16% Cu). The middlings are retreated in pneumatic-type flotation machines. The richest middling (cells 2-4) goes to a finisher cell and gives a concentrate (27.00% Cu) and a tailing (12.18% Cu) which with middling 2 (3.13% Cu) (cells 5-7) goes to a primary cleaner. The concentrate from the primary cleaner (19.98% Cu) goes to the finisher cell with the rich middling, while the tailings (3.37% Cu) plus the lean middlings (cells 8-12) make the feed to a secondary cleaner. The concentrates from the secondary cleaner (11.22% Cu) are fed to the primary cleaner and the tailings (1.96% Cu) return to the head of the circuit. The M.S. tailings (0.16% Cu) are concentrated in scavenger cells to give a product (1.05% Cu) for return to the head of the circuit and a final waste (0.15% Cu). Cu recovery is 91.34% at a total cost of \$0.6521 per ton of ore (1929) divided as follows (cents): breaking 8.56, crushing 2.75, primary grinding 15.28, secondary grinding 9.38, classifying, screening and conveying 3.86, flotation 9.32, dewatering and handling concentrates 3.29, assaying and sampling 1.17, tailings disposal 5.83, water 0.14 and miscellaneous 5.63. Reagent consumption (lbs./ton) in 1929 was lime 0.1806, xanthate 0.0787, fuel oil 0.1045, M.S. No. 14 pine oil 0.1571 and Risor pine oil 0.0485; or Na_3PO_4 0.0600, xanthate 0.0753, fuel oil 0.2402, M.S. No. 14 pine oil 0.1788, and Risor pine oil 0.0504. AHE (33c)

All-Flotation at North Broken Hill, Limited. Alfred Lowry. *Proceedings Australasian Institute of Mining and Metallurgy* No. 79, Sept. 30, 1930, pages 355-377; No. 82, June 30, 1931, pages 101-113.

The pulp after grinding is classified into fines and granular ore. The latter is diluted with alkaline H_2O to approximately 2 parts H_2O to 1 of solids (by weight) and maintained at approximately 0.005% Na_2CO_3 strength. The following reagents are added before flotation: eucalyptus oil-coal tar 0.038, K xanthate 0.019, Na silicate 0.058 and Na_2CO_3 0.509 lb. per ton of ore. Flotation of galena is almost instantaneous. Tailings from the first 8 cells are retreated with eucalyptus oil-coal tar 0.008, K xanthate 0.003 and Na_2CO_3 0.073 lb. per ton. The fines produce a similar Pb concentrate. A Zn concentrate is produced from tailings in both the coarse and fine circuit. Analysis of crude ore for June, 1930, was Pb 14.03, Zn 10.53, Fe 5.06, Mn 0.77, Cu 0.10, $Al_2O_3$0.53, CaO 1.20, S 9.77, insolubles 57.26, CO_2 0.50, undetermined 0.25% and Ag 8.3 oz. per ton. Pb concentrate (18.1% of feed) assayed Pb 70.0 Zn 5.7% and Ag 39.8 oz. per ton, and accounted for 94.1% of the Pb, 86.5% of the Ag and 10.1% of the Zn. Zn concentrate (17.0% of feed) assayed Pb 2.0, Zn 50.3%, Ag 2.8 oz. per ton and accounted for 2.5% of the Pb, 5.7% of the Ag and 83.6% of the Zn. Tailings (64.9% of the feed) assayed Pb 0.7, Zn 1.0% and Ag 1.0 oz. AHE (33c)

Magnetic Separation (33d)

Plant for Magnetizing and Concentrating Iron Ore. H. Sundholm. *Iron & Coal Trade Reviews,* Vol. 124, Jan. 1, 1932, pages 4-5.

A method is described for concentrating weakly-magnetic ores poor in Fe. The non-magnetic Fe oxide in these ores, heated in a special manner for a short time at a comparatively low temperature, is transformed into a highly ferromagnetic modification of Fe oxide. Among the ores amenable to this process are dogger-ore, limonite, and oolitic Fe ore. Working schedule and results of the treatment are described in diagrams and tables. Ha (33d)

Crushing (33e)

The Economics of the Preparation of Iron Ores. R. Sharp. *Iron & Steel Industry & British Foundryman,* Vol. 5, Dec. 1931, pages 103-104.

A simple discussion of the crushing, calcination, agglomeration, sintering, and briquetting of ores emphasizing the fact that the production of cheap pig Fe is the ultimate desire. CHL (33e)

The Absorption of Gold in Tube Mills. H. A. White. *Journal of the Chemical, Metallurgical & Mining Society of South Africa,* Vol. 31, Dec. 1930, pages 161-171; May, 1931, pages 294-298; Vol. 32, Aug. 1931, page 31.

Though concentration upon the surface of pebbles and tube linings is a real effect, it does not account for more than a minor portion of the total Au locked up in the tube. The remainder is held in the numerous joints in the linings, between the lining and the shell and in other crevices. AHE (33e)

Explosive Shattering of Minerals as a Substitute for Crushing Preparatory to Ore Dressing. R. S. Dean & John Gross. Report of Investigations No. 3118, *United States Bureau of Mines,* Feb. 1932, 5 pages.

Minerals contain enough cracks, cleavage planes and pores to permit effective shattering through expansion of expandable substances introduced into the pores. The bulk of the experiments reported made use of the expansive power of H_2O when suddenly released from pressures at a temperature sufficiently high to convert the H_2O to steam. Using 4 to 6 mesh quartz, maximum crushing was obtained by release from 150 lbs. pressure, using 50 cc. H_2O to 100 g. quartz, and after 4 days soaking. Experiments on ores indicate a differential crushing. Thermal considerations indicate a fuel cost of 5 cents per ton of ore, figuring coal at \$2 per ton and burning efficiency of 30%. AHE (33e)

MANUFACTURERS' LITERATURE REVIEWS

339 **Matrix Alloy**—The Cerro de Pasco Copper Corporation, 44 Wall St., New York, is distributing a 31 page pamphlet showing the application of Matrix Alloys, containing 48% Bi, 28½% Pb, 14½% Sn, 9% Sb, for mounting dies. The alloy freezes at 248° F. and has a tensile strength of 13,000 lbs./in.[2] Many illustrations show its use in anchoring dies for blanking, piercing, forming, drawing, etc. Where other methods are as simple or more applicable, the fact is frankly stated.

340 **X-Rays in Industry**—This 60-page booklet, prepared by the Eastman Kodak Co., Rochester, N. Y., suggests some of the industrial applications of X-rays in inspecting the internal construction of opaque materials. It states briefly how X-rays are produced, describes the necessary apparatus and gives some rules for the proper exposure and manipulation of radiographic films.

341 **Acid-Proof Tank Construction**—The U. S. Stoneware Co., Akron, Ohio, is sending out reprints of an article which appeared in *Industrial & Engineering Chemistry* entitled "Quick-Setting Silicate of Soda Cements for Acid-Proof Tank and Tower Construction." Details of representative types of acid-proof lining construction are given.

342 **Nevastain RA**—An attractive 20-page booklet sent out by the Associated Alloy Steel Co., Cleveland, Ohio, is devoted to their new stainless steel alloy containing chromium, copper, silicon and iron. A large part of the booklet is given to a discussion of its fabrication and applications.

343 **Luxit**—The Alpha-Lux Co. Inc., 192 Front St., New York, has issued a leaflet describing their "Luxit" for lining gas or oil fired crucible furnaces, for patching cupola linings and for lining ladles. The same company has also prepared several folders describing their "Liquitol A" for steel and "Liquitol B" for iron which are said to reduce cavities and porosities in castings and will not affect physical or analytical properties of steel.

344 **Buyers' Guide**—The International Nickel Co., 67 Wall St., New York, has issued the 1932 edition of their directory of manufacturers, fabricators and distributors of structural grades of nickel steels, corrosion-resistant steels, heat-resistant nickel-chrome-iron alloys and special ferro-nickel alloys.

345 **Metallic Zinc Powder**—Paints containing Metallic Zinc Powder have certain advantages over other paints for priming and finishing iron and steel, for galvanized metal and sheet zinc. They are discussed in a pamphlet distributed by the New Jersey Zinc Co., New York. Another interesting booklet prepared by the same company is entitled "The Light Reflection Value of Color in Paint."

347 **Furnaces**—The W. S. Rockwell Company, 50 Church Street, N. Y., has just issued three bulletins devoted to their various types of furnaces. No. 327 discusses their rotary carburizing furnaces both electric and fuel, No. 328 describes their rotary heat-treating furnaces for ferrous and nonferrous metals and No. 330 is devoted to their general industrial furnaces.

348 **Corrosion Resistance**—Bulletin 1506, sent out by the American Instrument Co., Washington, D. C., discusses the U. S. Navy method salt-spray equipment for determination of corrosion resistance and its value to producers and consumers of ferrous alloys.

349 **Boiler Water Level Recorders**—Bulletin No. 112, published by the Bailey Meter Co., Cleveland, Ohio, outlines the mechanical construction and various methods of installation of their boiler water level recorder. It describes the method for obtaining records of the true water level throughout the full range of the drum. The bulletin is fully illustrated.

350 **Painting Galvanized Iron**—An attractive booklet of this name has been prepared by the New Jersey Zinc Co., New York, N. Y. Complete instructions for painting both new and weathered galvanized iron and sheet zinc surfaces are given.

351 **Industrial Furnaces**—Catalog 105 of the Chicago Flexible Shaft Co., Chicago, Ill., shows a few representative types of the Stewart industrial furnaces. These furnaces are supplied to meet every requirement in the industrial field.

352 **Industrial Application of the X-Ray**—Bulletin No. 284 of the General Electric X-Ray Corp., Chicago, Ill., is a fully illustrated 36-page booklet containing several extracts from literature in the field of industrial science and a series of specific cases of the application of X-rays in industrial work.

ALPHABETICAL INDEX TO ADVERTISERS

◆ ◆ ◆

353 **Rolls**—Bulletin R-1001 of the United Engineering & Foundry Co., Pittsburgh, Pa., lists their rolls for every class of rolling mill work, hot and cold, ferrous and non-ferrous, for the largest and smallest mills and auxiliary equipment.

354 **Reference Book on Stampings**—The Geometric Stampings Co., Cleveland, Ohio, has published a 28-page booklet illustrated with charts, graphs and tables which will be useful to those using stampings, forgings and castings. Although the price is $1.00, a copy will be sent free to anyone writing for it on the firm's stationery and mentioning *Metals & Alloys*.

355 **Monel Metal Bolts**—Bulletin T-1 of the International Nickel Co., Inc., New York, N. Y., gives an outline of the properties of Monel metal bolts, describing the types available and discussing their impact and fatigue strength, and corrosion resistance.

356 **Plastic Fire Brick**—Quigley "Chromix" is a chemically neutral, plastic refractory. It is adapted for construction of monolithic furnace hearths and walls; for molding burner blocks and other special shapes and for quick, durable "rammed in" refractory repairs. A booklet describing it has been issued by the Quigley Co., New York, N. Y.

357 **Heat and Acid Resisting Castings**—Bulletin No. 21 of the Standard Alloy Company, 1679 Collamer Road, Cleveland, Ohio, lists the most popular analyses of Standard-Alloy together with safe workable loads at different temperatures. The figures derived are from long time duration from field results and tests, allowance having been made for creep.

358 **Supersensitive Relay**—A leaflet sent out by the American Instrument Co., Washington, D. C., describes their new supersensitive relay which will break 1320 watts with 4 milliamperes at six volts. In spite of extreme sensitivity, this new relay is ruggedly built and may be mounted in any position. No covers or special bases are required for these instruments.

359 **Diamite**—A leaflet describing this alloy white iron has been issued by the Weatherly Foundry & Mfg. Co., Weatherly, Pa. It is extremely hard and is said to have equalled the life of manganese steel castings under some conditions at a greatly reduced cost. Test data for the alloy are given and a list of suggested uses.

360 **Circle "L"**—Two folders sent out by the Lebanon Steel Foundry, Lebanon, Pa., are devoted to their alloy steels for high stresses and wear resistance, and their stainless steel alloys for corrosion resistance and heat resistance. An analysis of each alloy is given, together with a short description of its properties and suggested uses.

361 **Furnaces** — The Surface Combustion Corp., Toledo, Ohio, has issued two folders, one telling about their continuous liquid heat treating furnace and the other describing an installation of their continuous gas carburizing furnaces at the Chrysler plant.

362 **Weld Inspection by X-Ray**—The Claud S. Gordon Co., Chicago, Ill., has prepared a folder showing the results of X-ray examination of welds. Their laboratories are equipped to X-ray any industrial materials and all shapes and sizes of steel and other metals.

363 **Welded Truck Bodies** — The feature article of the April issue of *Oxy-Acetylene Tips*, published by the Linde Air Products Co., New York, N. Y., discusses the possibility of increasing the pay load of trucks by welding the bodies. Another article in the same issue is entitled "Salvage by Cutting."

GENERAL (0)

The Gas Industry's Research Program in Metallurgy. Eugene D. Milener (Industrial Research Representative, American Gas Association). *American Gas Association Monthly,* Vol. 13, Jan. 1931, pages 15-19.

Includes forging, bright annealing, decarburization during heat treatment and brass melting. The work on forging covers burning, overheating, scaling, decarburization and rates of heat penetration. These theoretical aspects being carried on by Department of Engineering Research of University of Michigan, with results to appear as technical papers principally before A. S. S. T. Work being conducted by W. E. Jominy. Practical phases of forging being worked out by Surface Combustion Corporation. Details the development of "Diffusion Flame Gas Forge," in which radiant energy from the flame penetrates a blanket of gas which surrounds steel billets and protects from scaling and decarburization. The work on bright annealing is summarized as follows: (1) Research in the laboratory has established the requirements which must be met to effectively bright anneal brass. (2) A process has been developed known as the "methanol" process. (3) A furnace has been developed on a scale adequate to demonstrate. (4) Brass shapes have been bright annealed in this furnace. (5) The working qualities of brass so annealed have yet to be fully demonstrated. (6) The cost must be determined. (7) Process is applicable to nickel silver. (8) Use of propane is now being studied. (9) Strand annealing of copper wire by use of propane has been successfully demonstrated. (10) Control mechanisms are being developed. (11) Strand annealing by this process permits the combining of annealing with tinning into one operation. (12) Same process is used for steel strip. Brass melting is being studied at present. Other projects are short cycle malleableizing, materials suitable for immersion gas burner tubes for zinc base die casting and galvanizing furnaces. RJC (0)

The Romance of Metals & Alloys. Z. Jeffries. *Conference on Metals & Alloys, Case School of Applied Science,* Cleveland, Ohio, Nov. 1931, Paper No. 6, 4 pages. Reprint from *Cleveland Engineering,* Vol. 24, No. 25.

The development of metals in the use of mankind is described: at first, iron and copper by primitive man; gold as a precious metal was a main factor of conquest and discovery; then the artificial production of iron, steel, brasses, bronzes. Modern civilization is extensively built around steel; the electrical industry, around copper; aircraft industry around aluminum. About 5000 different varieties of metals and alloys are being used today. The scientific study of properties and the methods applied are treated briefly. See editorial comment, *Metals & Alloys,* Vol. 3, Feb. 1932, page 28. HWG+Ha (0)

Tool Steel from the Consumer's Standpoint. H. G. Keshian (Chase Companies.) *American Society for Steel Treating, Preprint* No. 37, 1931, 8 pages.

Paper read and discussed before the Boston Convention of the Society in Sept. 1931. The author presents the idea that the tool designer should have more data on the quality of his materials on which to base his design. Producer classification is urged. See also *Metals & Alloys,* Vol. 2, Oct. 1931, page 203. WLC (0)

Patent Law. F. H. Rhodes. McGraw-Hill Book Co., New York, 1931. Cloth, 6 x 9½ inches, 207 pages. Price $2.50.

If one wants to know technical facts, but doesn't know the technical jargon in which they are ordinarily couched, one must get someone to translate them. A professor of German literature is not so good a translator of a metallurgical treatise as is a metallurgist who knows the facts that the author is discussing, even though his German is meager. If the metallurgist goes to the professor to clear up any grammatical details that elude him, the final result is wholly satisfactory.

In this book, the professor's role is reversed from that of our example. A professor of chemistry has gone into the very technical subject of patent law, and produced a book that gives the facts free from legal verbiage, or at least, with the verbiage relegated to the footnotes. He has called upon patent lawyers for assistance, and has taken counsel especially with one lawyer who himself has had chemical training, but he has written the book from the point of view not of the lawyer, but of the chemist, engineer or business man who wants to know how patent law may affect him, but doesn't want to take the time to become a patent lawyer himself to find out.

There are other books on the subject that give about the same information, but we have seen none that give it in so relatively painless a fashion. It is a readable book, because it is written from the right point of view. That it is not designed to be, and would probably not be acceptable to patent lawyers as a legal text book, should commend it to a wide group of readers.

While the reviewer finds nothing in the book to lessen the doubt he has whether our patent system is a national asset—the author clearly points out how the system may lend itself to chicanery and to abuse—yet, since the system is with us, it is often necessary to know how it works. The book discusses invention, discovery, utility, novelty, priority, abandonment, details in making and prosecuting an application, rights conferred, infringement, validity, rights of employers and employees, and gives some suggestions as to patent policy, i.e., what one might well seek to cover by patent, how to license, etc.

We should have liked to have had included a discussion as to whether inventions by Government employees are the property of the individual or of the public.

We were interested to learn that the first English patent was granted by Edward III for a "composition of matter," a philosopher's stone for transmuting base metals into gold. There have been later metallurgical patents that added just about the same amount to the store of human information as the first one. H. W. Gillett (0) -B-

The Fabrication of Plant in Acid-Resisting Steels. C. Cyril Hall (Thos. Firth & Sons, Ltd., Sheffield). *Sheet Metal Industries,* Vol. 4, Jan. 1931, pages 788-798; Feb. 1931, page 883.

Paper before the Institution of Welding Engineers. Part I. The author discusses all the forming processes as applied to steels of the composition 18% Cr, 8% Ni. He recommends practice for machining, shearing, drilling, milling, cold-forming, hot-working, riveting, and welding. Gas and electric welding systems are discussed in rather great detail and the use of electric welding is favored. Part II. Heat treatment after welding is recommended to eliminate stresses and to remove the effect of the precipitation from solid solution of carbides as a result of temperatures between 500° and 900° C. A pickling bath for removal of scale has the following composition:

Water	50	parts by volume
HCl	50	parts by volume
HNO_3	5	parts by volume
Restrainer	0.25	parts by volume

Operating temperatures between 50° and 60° C. are recommended with an immersion period of 15 mins. to be followed by washing and scrubbing. Soft and hard-soldering methods are discussed. AWM (0)

Value of Specifications in the Manufacture of Steel. J. Brunner. *Proceedings American Society for Testing Materials,* Vol. 31, Part 2, 1931, pages 959-962; *Commercial Standards Monthly,* Vol. 8, Nov. 1931, pages 145-146.

Stabilising Metals by Magnetism. Edward G. Herbert. *Metallurgia,* Vol. 5, Nov. 1931, pages 13-16, 25.

Previous work by the author has shown that, subsequent to rotation in a magnetic field, hardened steel and other materials undergo periodic fluctuations in hardness. It is now reported that the hardness can be stabilized at a high or a low value by subjecting the specimen to a stationary magnetic field. The stationary field first decreases the hardness, after which the hardness rises to an appreciably higher value which is apparently permanent. The effects of demagnetizing on the magnetically treated specimens was studied and it was found that the increased hardness was not dependent on the magnetism. In some cases the hardness of the demagnetized specimens increased while that of the magnetized ones remained constant. JLG (0)

The Organization of the Quality Production in Vereinigte Stahlwerke. (Die Organisation der Qualitäts-Wirtschaft in der Vereinigte Stahlwerke Aktiengesellschaft.) Karl Daeves & E. H. Schulz. *Mitteilungen aus dem Forschungsinstitut der Vereinigte Stahlwerke Aktiengesellschaft Dortmund,* Sonderheft 1, 1931, pages 1-16.

It is shown how the frequency curve of a certain occurrence can be used as excellent characteristic for the quality of a product. The application of this statistical method to the manufacture of a certain product from raw material to finished product is explained in all details and influences on purchasing, operation, testing, handling and research work. How such a program works out is shown on the concrete examples of a Cu addition to steel to increase the corrosion resistance which had to be verified. Ha (0)

The Application of Industrial Research. H. C. Dews. *Foundry Trade Journal,* Vol. 45, Sept. 24, 1931, pages 189-192.

After discussing the expenditures of the United States and German governments on research work, the author emphasizes the need for some active interest in research work in Great Britain. He supports his contention by quotations from various reports. A discussion follows of the manner in which the various research associations came into being. The question of applying the results of research work carried out by these associations is dealt with. Some space is devoted to the author's view of the best type of ideal development officer. The paper is followed by a discussion. OWE (0)

The Nature of the Metallic State. (Die Natur des metallischen Zustandes.) A. Eucken. *Zeitschrift für Metallkunde,* Vol. 23, Nov. 1931, pages 293-296; Dec. pages 329-334.

A discussion of the metallic state from the standpoint of modern atomic and molecular physics. RFM (0)

A Metallurgical Detective Story. *Metal Progress,* Vol. 19, June 1931, pages 94-98.

Metallographic evidence is made to solve an infernal machine murder. WLC (0)

Recent Developments in Iron and Steel. J. W. Donaldson. *Metallurgia,* Vol. 5, Dec. 1931, pages 51-52.

Includes brief discussion of methods of production and new alloys. JLG (0)

Specifications from the Standpoint of a Large Purchaser of Engineering and Special Materials. J. W. Bancker. *Proceedings American Society for Testing Materials,* Vol. 31, Part 2, 1931, pages 987-995.

Where Are We Going With the New Materials? George S. Brady. *Product Engineering,* Vol. 3, Jan. 1932, pages 22-24.

The developments of 1931, particularly in stainless steels, light alloys in the use of transportation, and of cast iron are reviewed. More standardization and classification of alloys is considered desirable. Ha (0)

Metallurgy of Alloying. A. A. Bates. *Conference on Metals & Alloys, Case School of Applied Science,* Cleveland, Ohio, Paper No. 1, Nov. 1931. Mimeographed, 6 pages.

General discussion, as opening paper of the conference. The properties of an alloy bear no simple or predictable relationship to the properties of the component metals. When 2 or more metals are alloyed together, the result is usually a surprise. Hence, the complexity and importance of metallurgy. Brief comment is given on mechanical mixtures, solid solutions, intermetallic compounds, slip interference, etc. HWG (0)

PROPERTIES OF METALS (1)

Solution of Metals in Non-Metallic Solutions: Some of Their Physical and Chemical Properties. CHARLES A. KRAUS. (Brown Univ.) *Journal of the Franklin Institute,* Vol. 212, Nov. 1931, pages 537-562.

Presented at meeting of Franklin Institute, Jan. 15, 1931. The present view generally accepted is that characteristic properties of metals are due to presence of electrons which are free to move within the body of the metal, although subject to certain restrictions. Positive constituent of a metal has no metallic properties, the negative constituent, only, imparts to a metal those properties that we call metallic. Alkali and alkaline earth metals dissolve in liquid ammonia with the formation of ions. Positive ions are normal ions of these metals, while negative ions are electrons. Physical and chemical properties of these solutions are in accord with this view. Metallic compounds, when they dissolve in liquid ammonia, form ions of the normal type; the more electronegative element forms the anions. The metallic condition of matter is restricted to matter in a highly condensed state. If the atoms are separated, whether in solution or as a vapor, the metallic properties disappear. In an ionizing medium, however, the electron retains certain of the properties that it possesses in elementary metals. DTR (1)

The Magnetic Susceptibility of Iron at Temperatures Slightly Above the Curie Point. (Susceptibilité magnétique du fer a quelques degrés audessus du point de Curie.) L. NÉEL. *Comptes Rendus,* Vol. 194, Jan. 18, 1932, pages 263-265.

The author reports the results of a study of the magnetic properties of Fe at temperatures immediately above the Curie point, over which small range the susceptibility does not obey the Weiss law. The article is accompanied by 1 table and 1 diagram, which give details of the results of his experiments. OWE (1)

The Nature of Metals in Relation to their Properties. EARLE E. SCHUMACHER. *Scientific Monthly.* Vol. 34, Jan. 1932, pages 22-30.

The nature of metals and the meaning of hardness is explained by the lattice structure and the planes in them determined by the position of the atoms. Sliding or slipping may take place between these planes, and on the resistance to this sliding depends the hardness of the metal. This is explained and illustrated by several photomicrographs of lead showing various stages of hardening. Until all properties of the structural elements are known the behavior of metals can not be completely understood. Ha (1)

Presence of Electro-Motive Forces in Short-Circuited Metallic Circuits of Uniform Temperature (Existenz elektromotorischer Kräfte in geschlossenen metallischen Stromkreisen von gleichmässiger Temperatur). O. SCARPA (Royal Polytechnikam of Milano). *Zeitschrift für physikalische Chemie,* Abt. A, Vol. 154, Sept. 1931, pages 225-226.

The occurrence of e.m.f.'s could be detected in circuits consisting of metallic conductors at uniform temperatures if the metals in contact are forming solid solutions or intermetallic compounds. The short-circuited chains investigated were composed as follows: Cu/Hg (Me) Cu, wherein Me = Zn, Cd, Ag, Au, Pb, Bi, Ni, Fe, Al. Volta's law of electromotive series and some further thermo-electric laws only hold true if the metals in touch with each other are indifferent to each other. Critical comment on a recent publication of K. Schwarz is included (*Zeitschrift für physikalische Chemie,* Abt. A, Vol. 154, Apr. 1931, pages 245-254).

Cadmium. FRED GROVE-PALMER. *Metal Industry,* London, Vol. 39, Aug. 28, 1931, pages 195-196, 206.

Brief mention is made of the preparation of pure cadmium and of electroplating steel with cadmium for rust proofing purposes. PRK (1)

The Appearances of the Forbidden Lines and the Intensity Modifications of the Spectra of Mercury, Cadmium and Zinc Under High Frequency Excitation. J. OKUBO & E. MATUYAMA. *Physical Review,* Vol. 38, Nov. 1931, pages 1651-1655.

With an oscillator of a frequency of 3×10^3 cycles/sec. the intensity modifications of the spectra of Hg, Cd and Zn were studied. The singlet series and the intercombination lines which begin on the singlet levels were straightened as has been observed by previous investigators in the case of Hg and the results were extended to the case of Cd and Zn. The intensity relations of the forbidden line $1S - 2p_1$ of Hg were studied under this condition of excitation and also $1S - 2p_{1,3}$ of Cd were observed. The relation between the lines and the bands are discussed. Some consideration is also given to the conditions of excitation from the intensity modifications of lines. WAT (1)

Magnetization and Thermal E. M. F.'s. S. R. WILLIAMS. *Physical Review,* Vol. 38, Jan. 1932, page 368.

The paper is one of those presented in a Symposium on Magnetization by the American Physical Society, Sept. 1931. The thermal e.m.f. developed between transversely and longitudinally magnetized wires is shown for Ni and Fe. The experiments show that temperatures determined by thermocouples in magnetic fields are not reliable unless the elements of the couple are unaffected by the field. A number of elements are displaced in the thermo-electric series by being in a magnetic field. WAT (1)

Some New Experimental Methods in Ferromagnetism. S. L. QUIMBY. *Physical Review,* Vol. 38, Jan. 1932, pages 343-353.

A paper in the Symposium on Ferromagnetism of the American Physical Society, Sept. 1931. A brief description of certain methods which have been devised for observing the magneto-elastic, mechanical and thermal properties of single crystals of nickel, as well as polycrystalline specimens of the same material are described. Attention is directed to a special process for refining the nickel. The general procedure is similar to that developed by Bridgman for the production of single metallic crystals. The novelty of the present arrangement, however, consists in those features which permit the use of this method at a temperature of 1500° C. WAT (1)

The Specific Volume of Liquid Iron (Das spezifische Volumen von flüssigem Eisen). E. WIDAWSKI, *Stahl und Eisen,* Vol. 51, Oct. 15, 1931, pages 1290-1291.

Investigations of F. Sauerwald and his collaborators are briefly reviewed. The work at the high temperatures of molten iron necessitated the development of a special method in order to measure the density of Fe-C alloys at high temperatures. The table below gives the values obtained.

Carbon content %	Melting point ° C.	Specific Volume at melting point	Specific Volume at 1600° C.	Temperature Coefficient	Specific gravity at melting point	Specific gravity at 1600° C.
0.0	1533	0.1402	0.1405	0.05×10^{-4}	7.13	7.12
0.5	1480	0.1408	0.1411	0.06×10^{-4}	7.10	7.08
1.0	1458	0.1412	0.1417	0.06×10^{-4}	7.08	7.05

Frictional Electric Charges Upon the Surfaces of Single Metal Crystals. P. A. MAINSTONE. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Series 7, Vol. 12, Aug. 1931, pages 535-538.

Measurements of the frictional charges produced by very light rubbing upon the surfaces of metals under varying gas pressure did not reveal conclusively any marked differences between the tribo-electric effects upon the various faces of a single metal crystal or between polycrystalline and single crystal surfaces. Ha (1)

The Magnetization-Temperature Curves of Iron, Cobalt and Nickel. F. TYLER. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Series 7, Vol. 11, Feb. 1931, supplement pages 596-602.

The theoretical significance of the spontaneous magnetization-temperature curves based on the Weiss theory is discussed, certain modifications required by quantum considerations are added. The electron spin is regarded as the fundamental magnetic element operative in the three ferromagnetic metals Fe, Co and Ni. 14 references. Ha (1)

On the Nature of the So-Called Radio Colloids (Ueber die Natur der sogenannten Radiokolloide). O. WERNER (Kaiser Wilhelm Institut für Chemie, Berlin-Dahlem). *Zeitschrift für physikalische Chemie,* Sect. A, Vol. 156, Sept. 1931, pages 89-112.

The author endeavors to throw light upon the nature of the so-called radio-colloids by means of a photographic and and a centrifugal method and proves the phenomenon being based on adsorption in the case of radio-active lead and bismuth. Experiments on the influence of additions of electrolytes disclose the influence exerted by the charge and solubility upon the adsorption ability of the radio elements. EF (1)

The Resistance of Bismuth in Alternating Magnetic Fields. WILLIAM W. MACALPINE. *Physical Review,* Vol. 37, Mar. 1931, pages 624-633.

Apparatus for producing a field of 100 gauss r.m.s. at 10^6 cycles with a 50 watt tube is described. Also a method of measuring the behavior of bismuth wire in such a field at liquid air temperature. For this purpose a potentiometer has been developed for the measurement of the amplitude and phase of voltages at frequencies up to at least 10^6 cycles/sec. It was found that the resistance of the Bi follows the instantaneous values of the field, having a magnitude at any instant equal to what it would have if the field at that instant were maintained constant. The precision of the magnitude calculated from the various factors involved is $\pm$ 3.5% and the experimental value is normal within this precision. At 55 kilocycles and at room temperature the resistance of the Bi was also found to be normal in magnitude and phase. WAT (1)

Chemical Valency and Spectral Properties. (Chemische Valenz und die Eigenschaften der Spektraltherme.) A. T. WILLIAMS (University of La Plata) *Physikalische Zeitschrift.* Vol. 32, Nov. 15, 1931, pages 870-875, 6 references.

Data is given covering the relationship between chemical valency and spectral properties of atoms of the following elements: B, Al, Ga, In, Te, C, Si, Sn, Pb, N, P, As, Sb, Bi, O, S, Se, Te, F, Cl, Br. EF (1)

On the Resistance of Lead to High-Frequency Currents at Superconducting Temperatures. J. C. MCLENNAN, A. C. BURTON, A. PITT & J. O. WILHELM. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Series 7, Vol. 12, Sept. 1931, pages 707-719.

The resistance of Pb to steady currents becomes abruptly of vanishingly small magnitude when the temperature of 7.2° absolute is reached. This investigation was made to ascertain whether or not this abrupt change occurs for high-frequency currents of the order of 10^7 cycles/sec., also. Test methods and apparatus are described. A definite conclusion could be made: there is no discontinuity in the resistance of Pb to currents of 11×10^6 frequency when passing from above to below the superconducting point and down to 4.2° K. Pb, in the superconducting state, shows no apparent decrease in resistance below 7.2° K., but for high frequency currents a decrease for temperatures down to 4.2° K. was obtained. Ha (1)

The Electrical Conductivity of Ruthenium, Ruthenium Carbide and Tungsten Carbide. J. C. MCLENNAN, J. F. ALLEN & J. O. WILHELM. *Transactions of the Royal Society of Canada,* 3rd Series, Vol. 25, Sec. 3, May, 1931, pages 13-17.

The authors made an investigation of the electrical conductivity of ruthenium at low temperatures in 1929 and found that the material became superconducting at a temperature of 2.04° K. Subsequent work by Meissner failed to support the contention that ruthenium was superconducting even at temperatures as low as 1.13° K. The authors, as a result of the investigation referred to, have shown that the superconductivity of ruthenium examined by them in 1929 was due to the presence of tungsten carbide. The article is accompanied by 11 tables and 4 diagrams. OWE (1)

PROPERTIES OF NON-FERROUS ALLOYS (2)

Bismuth Bearing Type Metal. (Zur Kenntnis der wismuthaltingen Schriftmetalle.) E. R. Thews. *Die Metallbörse,* Vol. 21, Feb. 28, 1931, pages 388-389.

The most important Bi-bearing type metals are discussed with respect to their chemical composition, tensile strength, elongation and Brinell hardness respectively.

Influence of Pouring Temperature, Cooling and Solubility for Gases on Defects and Strength of Aluminum Castings. (Der Einfluss der Giesstemperatur, Abkühlung und Gaslöslichkeit auf Fehler und Festigkeit bei Aluminumgussstücken.) M. Barbero. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Nov. 13, 1931, pages 882.

The influences of melting and pouring temperature of light metals is shown in the following table which gives average values:

Melting Temperature °C.	Pouring Temperature °C.	Strength kg./mm.^{2}
760	630	14.5
740	640	13.1
740	660	12.7
730	680	12.2
880	680	11.8
740	700	6.8

At higher temperatures than 750° the alloy absorbs great quantities of gases from the atmosphere and combustion gases; they are, however, not all injurious, as they partly increase the fluidity or reduce shrinkage. Ha (2)

Precious Metal Alloys. R. C. Brumfield. *Transactions American Society for Steel Treating,* Vol. 19, Feb. 1932, pages 333-367.

Includes discussion. See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 2. WLC (2)

Aluminum and Its Alloys in Aircraft. T. W. Bossert (Aluminum Co. of America). *Aero Digest,* Vol. 20, Jan. 1932, pages 54-55.

A brief review of the properties and applications of the 2 high strength alloys, Al-Cu-Mn-Si (25ST), and Al-Mg-Si (51ST). The difference in their properties and the reason of their high strength is outlined. Alclad 17ST is described briefly. It is also pointed out that Al bronze powder has wide application where protection against sunlight, moisture and salt water plays a part in the aircraft industry. Al pigmented paints are widely used as protective coatings for metal in those cases where corrosion is to be avoided, especially where the structure is exposed to the sunlight. WAT (2)

Some Properties of Silicon—Aluminium Bronzes. L. J. Brice. *Engineering,* Vol. 131, Apr. 10, 1931, pages 498-500.

Condensed from paper read before the Institute of Metals, London, March 12, 1931. See *Metals & Alloys,* Vol. 2, May 1931, page 94. LFM (2)

Copper-Nickel Special Alloys. (Kupfer-Nickel-Sonderlegierungen.) M. Ballay. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Nov. 13, 1931, page 882.

These alloys are used where high corrosion resistance is demanded. Three groups are formed: 25-30% Ni, 45% Ni, and 65-70% Ni, of which the 2 last are the most important; to the last belongs Monel metal. For stresses of friction and compression Sn-Cu-Ni alloys are used successfully, for instance, 54% Ni, 33% Cu, 13% Sn; the hardness increases with the Sn-content. The hardness with the same Sn content decreases if the Cu content decreases from 50 to 30%. The mechanical properties of Si-Cu-Ni alloys are produced by heat treatment at high temperatures; the same method is successfully applied for Al-Cu-Ni alloys. An alloy of 83% Cu, 15% Ni, 2% Al if quenched in water from 1000° C. has 3 times the hardness. These latter alloys are particularly resistant against corrosion of sea water. Ha (2)

Some Magnetic Alloys and Their Properties. H. H. Potter. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Series 7, Vol. 12, Aug. 1931, pages 255-264.

It is shown that the ternary system Ag-Mn-Al possesses ferro-magnetic properties with a maximum saturation intensity of about 70 units/cm.^{3} at or near the point represented by 5 atoms of Ag, one of Mn and one of Al. The alloys in this system are, therefore, less magnetic than those of the Cu-Mn-Al system (the Heusler alloys) which have a Curie point of about 360° C. and an enormous coercive force which in the most magnetic specimens is about 5000 gauss. 2 magnetic compounds are found in the binary system Mn-Sn. The first, $SnMn_4$, has a saturation intensity of about 100 units and a Curie point at 150° C. The other is probably $SnMn_2$ with a saturation of 470 units and a Curie point at about 0° C. Ha (2)

Britannia Metal. (Britannia Metall.) R. Thews. *Die Metallbörse,* Vol. 21, Mar. 14, 1931, pages 483-484; Mar. 21, 1931, page 533.

Seventy-seven complete analyses of Britannia Metals and pewters are presented and the physical properties of the most important Sb/Sn alloys are discussed and the influence exerted by Cu, Zn, Fe, Pb is considered. EF (2)

Gun Metal. (Geschützbronze.) E. R. Thews. *Die Metallbörse,* Vol. 21, Mar. 21, 1931, pages 531-532; Mar. 28, 1931, pages 579-580.

Chemical composition and physical properties are compiled in 10 tables. EF (2)

Tempered Wires, Strength Varies with Size. R. C. Jordan. (Wickwire Spencer Steel Corp.) *Metal Progress,* Vol. 21, Jan. 1932, pages 62-65.

The tensile strength of oil tempered spring wire of the same composition is found to vary according to $T = 138{,}000/\sqrt[4]{d} - 1600/d$ where d is diameters between 0.030 in. and 0.562 in. Within the practical range of hardness and ductility the ratio of the limit of proportionality to the ultimate strength and ratio of the true elastic limit range between 75 and 80% of the ultimate tensile strength. The torsional breaking stress and the torsional elastic limit are proportional to the ultimate strength in tension. WLC (2)

Brass, Bronze and Copper Alloys. W. R. Hibbard. *Paper prepared for the Conference on Metals and Alloys.* Case School of Applied Science, Cleveland, Nov. 1931, 7 pages. Mimeographed.

A detailed description is given of all the copper products of the American Brass Company, their composition, treatment, and practical uses. Ha (2)

Magnesium Alloys. L. B. Grant. *Conference on Metals & Alloys,* Case School of Applied Science, Cleveland, Ohio. Paper No. 5, Nov. 1931. Mimeographed. 2 pages.

Brief general statement as to properties and uses. The low cost per unit volume at present prices is stressed. Castings with 8% Al, 0.4% Mn may be heat-treated to 38,000 lbs./in.^{2}, 8% elongation. Wrought alloys with comparable properties are similar, but contain less Al. These have 2/3 the strength of mild steel with ¼ the weight. HWG + Ha (2)

Centrifugally Cast Monel Metal. J. E. Hurst. *Metal Industry, London,* Vol. 39, Aug. 21, 1931, pages 171-172.

The properties of Monel metal and of silicon Monel metal are given. PRK (2)

Heat-treating and Forging Some Light Alloys. W. C. Devereux (High Duty Alloys, Ltd.). *Metallurgia,* Vol. 5, Dec. 1931, pages 45-50.

Discusses properties, working and heat treatment of several Al alloys, including Duralumin, "Y" alloy and alloys developed by the Rolls Royce Co. Gives photographs and micrographs of satisfactory and unsatisfactory forgings. The desirability of carefully controlled heat treatment is emphasized. JLG (2)

Ferro-magnetic Platinum-Chromium and Iridium-Chromium Alloys. (Ueber ferro-magnetische Platin-Chrom and Iridium-Chrom Legierungen.) E. Friederich. *Zeitschrift für technische Physik,* Vol. 13, Jan. 1932, page 59.

Pt-Cr alloys with 2, 5, 10 and 15% Cr were made by sintering powder of Pt and Cr. All these alloys proved to be ferromagnetic, the 10% Cr alloy showing the strongest ferromagnetism. In determining the ferromagnetic properties of a 10.1% Cr alloy the intensity of magnetization was found to be about 15 times smaller than that of Fe, the coercive force amounted to about 65 Örsted which about corresponds to that of tungsten magnet steel. An Ir-Cr alloy with 10% Cr is also ferromagnetic. The detailed results of the investigations on the above alloys are to be given in a later paper. GN (2)

Effect of Casting Temperature and Additions of Iron on Bearing Bronze. C. E. Eggenschwiller. *Technical News Bulletin Bureau of Standards,* Jan. 1932, page 6; *Bureau of Standards Journal of Research,* Vol. 8, Jan. 1932, pages 67-77.

A study has been recently made at the Bureau of Standards on the effect of casting temperature and additions of Fe on the properties of bearing bronze material consisting of 80% Cu, 10% Sn and 10% Pb. In addition to determinations of hardness and microstructure of this leaded bronze, several test methods were employed which simulated certain phases of actual service conditions. These tests included deformation under pounding and resistance to wear, both dry and in the presence of a coolant. As bearings are usually above room temperature while in operation, a considerable number of the tests were made at elevated temperatures. In the study of 80-10-10 bronze, cast at temperatures varying from 1850° to 2120° F. it was found that as the casting temperature, the grain size, and the resistance to wear were increased the hardness decreased slightly, and a slight tendency was noted for more even Pb distribution. Casting the bronze at about 2000° F. caused a decrease in the resistance to impact or lowered the toughness, as shown by the notch test. The deformation under pounding was a minimum in specimens cast between 1900° and 2000° F. Although Fe is not usually added intentionally to leaded bronzes, small amounts are often accumulated during the process of manufacture through the use of scrapped bearings, iron stripping rods, and so on. While the Fe content is quite small in most cases, the effect of this element is generally considered harmful. In the reported investigation the Fe content, which varied from 0-1% was studied. In general, it was found that additions over 0.3% Fe were detrimental to the bronze investigated. Small additions of Fe up to 0.5% decreased the resistance to wear and increased the hardness. When the Fe content exceeded 0.3% segregation of the Pb particles occurred, the grain size was reduced, and a decrease was noted in the notch toughness. Additions of Fe up to 1% increased the resistance to pounding. WAT (2)

New Aluminum-Tungsten Alloy in Germany. *Iron Age,* Vol. 127, Jan. 8, 1931, page 218.

A new alloy of Al in which W is used is being produced commercially in Germany under the trade name of "Benit." The alloy consists of 96.91% Al, 2% Cu, 0.45% Mn and 0.27% W. It is claimed by the maker to be easily welded, forged and drawn and has high tensile strength and hardness. (2)

Antifriction Alloys (Alliages antifriction graphites, leurs applications au matérial roulant des Compagnies de Chemins de fer). *Aciers Spéciaux, Metaux et Alliages,* Vol. 6, Apr. 1931, pages 209-211.

The characteristics of Pb base and Sn base antifriction alloys are compared with those of the graphitometal "France." Graphitometal "France," for which no chemical composition is given, performs betters than other alloys. GTM (2)

Cemented Tantalum Carbide. Floyd C. Kelley (General Electric Co.). *American Society for Steel Treating, Preprint* No. 14, 1931, 9 pages.

Paper read and discussed before the Boston Convention of the Society in Sept. 1931. The author describes the preparation of tantalum carbide and various binders used in forming tools of this material. Comparative tests of tool performance of tungsten and tantalum carbides are given. WLC (2)

M.V. "C" Aluminium Silicon Alloy. L. E. Benson. *Metallurgia,* Vol. 5, Jan. 1932, pages 93-94.

The alloy is modified by a new process developed by the Metropolitan-Vickers Electrical Co. The alloy as cast has a tensile strength of about 10 tons/in.^{2} and an elongation of 10%. The properties do not vary with the size of the casting, and the castings are free from pin holes. It also has a good resistance to corrosion. JLG (2)

High-Speed Steels (Die Schnelldrehstähle). WILHELM OERTEL & ARTHUR GRUTZNER. Verlag Stahleisen m.b.H., Düsseldorf, 1931. Cloth, 6 x 7¼ inches, 223 pages. Price 12 RM.

All phases relating to the production and utilization of high-speed steel are discussed within the brief compass of this book. The arrangement of the subject matter and the relative space devoted to each phase of the subject could hardly be improved. The book was written primarily to present critically the studies and developments of high-speed steels made within the past few years, but important older work is also discussed. A gratifying feature of this book is the clear discussion of studies described in English. Much of the authors' work is of course included, but not to the exclusion of important work by other investigators.

The book begins with a short history of the development of high-speed steel, which is followed by a discussion of the various elements used in such steels, including their occurrence in nature and their binary alloys with iron. The production of high-speed steel is then described and the causes of several defects common to improperly made steel are discussed. The heat treatment of the steel is then considered in some detail. The sections of the book which are probably the most valuable, then follow; they deal with physical properties and cutting life of high-speed steels. The subject matter of these 2 sections is particularly well presented, and warrants study by anyone interested in the metallurgy of high-speed steels.

The next section discusses the cast high-speed steels and the data given there simply serves to point out that such steels are inferior to wrought steels, which is attributed to the inability to produce the desired carbide distribution in the cast material. The next section briefly considers alloys of the Stellite type and tungsten carbide cutting tools.

The final section of the book proper lists the patents for high-speed steels issued by 6 countries. The analyses covered by these patents are also given. An amusing figure in this section is one in which the number of patents granted on high-speed steel per year is plotted against the year—the curve has a pronounced peak during the war years. 20 patents being granted in one year. References are also given to patents on alloys of the Stellite type and tungsten carbide materials.

One of the most interesting parts of the book is the portion of the appendix in which the effects of various alloying elements on the cutting life of high-speed steels as determined by various investigators are tabulated.

J. L. Gregg (3)-B-

The Use of Cast Iron in the Non-Ferrous Industry. A. L. NORBURY. *Foundry Trade Journal*, Vol. 45, Dec. 24, 1931, pages 388-390; *Metal Industry*, London, Vol. 39, Dec. 18, 1931, pages 587-590.

A paper dealing largely with effects of chemical composition and microstructure on the mechanical properties of cast iron and on the relationship between composition and growth in cast iron. Special reference is made to "Silal" and to the use of this material in the manufacture of various heat-resisting parts. The article is accompanied by 13 diagrams and 1 table. PRK+OWE (3)

The Relation between Different Hardness Numbers of Cast Iron and Chill Castings. (Die Beziehung zwischen verschiedenen Härteziffern bei Gusseisen und Hartguss.) A. WALLICHS & H. SCHALLBROCH. *Maschinenbau*, Vol. 10, Jan. 1, 1931, pages 18-20.

The relationship between Rockwell hardness, Brinell hardness, Shore hardness, Duroscope hardness, drop hardness, Herbert pendulum hardness is given diagrammatically for cast iron and hard castings. MAB (3)

Recent Developments in Cast Iron. J. G. PEARCE. *Metallurgia*, Vol. 5, Jan. 1932, pages 81-82 and 92.

The developments of austenitic irons and heat-resistant irons are stressed. JLG (3)

Anti-Slipping Steel (Griffiger Stahl). P. WIESSNER. *Dinglers Polytechnisches Journal*, Vol. 346, Nov. 1931, pages 182-183.

The difficulties experienced with rolls employed in refractory industry are pointed out. The frequent failures precipitated the development of a special steel known as "Karamitstahl," the analysis of which compares as follows with the cast steel formerly used:

Karamitstahl	Traditional cast steel
0.5 - 0.7% C	0.3% C
0.7 - 0.8% Si	0.15 - 0.18% Si
1.2 - 1.6% Mn	0.6% Mn

EF (3)

The Properties of Pig Irons from Various Sources. (Roheisensorten verschiedener Herkunft.) A. WAGNER. *Giesserei-Zeitung*, Vol. 27, Aug. 1930, pages 403-412.

Chemical analysis is not an exclusive criterion of the value of pig Fe, as many varieties of the same composition exhibit different properties. The behavior of 17 types of pig Fe, such as English hematite, foundry and Swedish charcoal Fe, was investigated by melting and remelting several times in crucibles, under as constant melting conditions as possible, and examining specimens for tensile and bending strength, hardness and microstructure. The first melting resulted in materials of low tensile strength, 8.5-12 kg., and low bending strength, 18-19 kg. Repeated remelting improved the physical properties: after the 4th melting the tensile strength increased 100% without any appreciable change in composition. Numerous photomicrographs are reproduced. (3)

Values of Hardness of Castings with Different Wall Thickness. (Hartewerte von Gussstücken mit verschiedener Wandstärke.) H. UHLITZSCH. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Nov. 27, 1931, pages 892-894.

Recent investigations have shown that, especially for machine tools, the specification of a Brinell hardness of 200 is of no value whatever if no other values of strength are specified at the same time. An attempt is made to develop hardness diagrams which take into account the contents of Si and C and the dimensions of the castings. Ha (3)

Eutectic Cast Iron. F. K. NEATH. *Bulletin British Cast Iron Research Association*, Vol. 3, Oct. 1931, pages 38-41.

Based upon the argument of Osann that Fe which casts well and gives no difficulties with shrinkage and unsoundness and in the cold state represents a close-grained pearlitic structure, must be eutectic in composition, the relationship between C and Si has been investigated and it was found that a variation of 0.1% C must be compensated by a variation of 0.2% Si in the opposite direction. The thickness of a casting therefore gives definite indication what the contents of Si and C must be. Several such examples for finding the eutectic composition are given. See also "Iron Castings with Eutectic Structure," *Metals & Alloys*, Vol. 3, Feb. 1932, page MA 31. Ha (3)

Hard Manganese Steel. The Present Status of its Production (Mangan-Hartstahl. Ueber den heutigen Stand seiner Herstellung.) K. K. VON SCHEELE. *Giesserei Zeitung*, Vol. 27, Feb. 15, 1930, pages 98-100.

After a brief reference to the method of manufacturing Mn steel, the author discusses the properties of the material and the difficulties of using it. He points out how little data is available. He doubts the comparability of published analyses. The Mn content drops considerably from the moment when the bath is ready to the end of the casting operation and, in addition, the C content rises during the reheating of the steel. (3)

Experiments to Elucidate the Question of Danger by Pressure in Cast-Iron. (Versuche zur Klärung der Frage der Druckgefahr von Gusseisen.) M. ROS & A. EICHINGER. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Dec. 4, 1931, page 923.

Tests were made to ascertain the behavior of cast-iron in the presence of 1, 2 and 3-axial tensional states. The structural texture determines the behavior. The results for tensile and pressure tests, tearing strength, kind of fracture, and the changes occurring in the structures at fracture are described and discussed in detail. Ha (3)

Influence of Shaping and Heat Treatment on the Properties of Steel. (Der Einfluss der Wärmebehandlung auf die Eigenschaften des Stahles.) G. SACHS. *Die Wärme*, Vol. 54, Nov. 28, 1931, pages 888-889.

A résumé of the latest investigations on the shaping and heat treatment of steel. The crystals in sheets are usually arranged in a regular manner which results in different properties along different directions. The aging phenomenon is probably intimately connected with the precipitation hardness. Residual stresses remain after hot and cold working. Internal stresses can be revealed by X-ray examination. The γ and α transformation can be suppressed by rapid cooling. The transformation into martensite takes place abruptly. A tetragonal atomic arrangement occurs in martensite which may be considered as a medium between the spatial structure of austenite and ferrite, respectively. The tetragonal crystals are arranged in a strictly regular order, i.e., in 24 different positions with reference to the austenite, thus forming the characteristic needle-like structure of martensite. Nitrogen in steel acts very similarly to carbon. EF (3)

The Heredity of Cast Iron (Beitrag zur Frage der Vererbung von Gusseisen). H. THYSSEN & E. BUFFET. *Giesserei mit Giesserei Zeitung*, Vol. 18, Nov. 6, 1931, page 866.

The view formerly held that the size of the graphite lamellae in the original pig iron influences, to a great extent, the properties of the cast iron is again confirmed. Very large graphite lamellae result in scrap. Casts of second melts show a finer grain of the lamellae. Ha (3)

Low Alloy Steel for Structures. RICHARD TULL. (Electro-Metallurgical Co.) *Metal Progress*, Vol. 21, Feb. 1932, pages 35-38.

The author describes the properties of "Cromansil," a low alloy steel for structural purposes made to the following composition limits: Cr 0.4-0.6%, Mn 1.1-1.4%, Si 0.7-0.8%, and C 0.1-0.65%. With 0.26% C this alloy steel will show 96,000 ultimate strength, 59,000 yield point with elongation of 28% in 2 in., and reduction of area 62%. This alloy welds readily. Normalizing subsequent to welding is unnecessary except in plates heavier than 1 in. with C in excess of 0.25%. Cromansil can be rolled, machined, drawn, pierced and worked generally in the same ways as C steel. WLC (3)

Some Recent Developments in Automobile Cast Iron. T. R. TWIGGER. *Foundry Trade Journal*, Vol. 45, Dec. 17, 1931, pages 375-378.

An article, accompanied by 12 diagrams and 3 tables, in which attention is paid to the improvements which have been made in cast iron of recent years, and the methods whereby these improvements have been applied to centrifugal castings. The results of heat-treating centrifugally cast iron containing 0.50% Ni and 0.20% Cr are dealt with in considerable detail. Some attention is devoted to austenitic cast iron containing 14% Ni, 7% Cu, and 2.5% Cr. Situations in which heat-treated iron has been used with satisfactory results are described. OWE (3)

On the Magnetostriction of Iron-Nickel Alloys. Y. MASIYAMA. *Kinzoku no Kenkyu*, Dec. 1931, pages 649-660 (In Japanese); *Science Reports Tohoku Imperial University*, Vol. 20, Oct. 1931, pages 574-593 (In English).

The magnetostriction of Fe-Ni alloys in different concentrations was measured for (1) volume change, (2) longitudinal length change, and (3) transverse length change. In each case an anomalous change occurred in the region of 20-35% Ni, corresponding to a mixture of α and γ solid solutions. The transverse change of length is nearly the reverse of the longitudinal change and the volume change is the differential effect of these two. The greatest volume change occurred at 30% Ni content and at the field intensity of 1050 gausses. TM+Ha (3)

The Qualities of Cast-Iron for Guide Faces of Machine Tool Beds and Means for its Production. (Die Eigenschaften des Gusseisens guter Gleitbahnen von Werkzeugmaschinenbetten und Wege zu dessen Herstellung.) RUD. MARKER. *Giesserei mit Giesserei-Zeitung*, Vol. 18, Nov. 27, 1931, pages 901-905.

The usually required qualities of good slide faces are discussed; the most pronounced characteristic is a pearlitic, eutectic cast iron poor in Si and C. Cast-iron cast in metal (chill) molds is not suitable. Ha (3)

CORROSION, EROSION, OXIDATION, PASSIVITY & PROTECTION OF METALS & ALLOYS (4)

Corrosive Measures Adopted to Prevent Water Pipe Corrosion. ROBERT SPURR WESTON. *Water Works Engineering*, Vol. 85, Feb. 10, 1932, pages 162.

Excerpts from a paper read before the American Water Works Association. Conditions rapidly improved when a lime treatment plant was operated to remove CO_2 and to raise the pH value to 8.0. CBJ (4)

A Study of Abrasion. SEIZO SAITO. *Science Reports of the Tohoku Imperial University*, Sendai, Japan, Vol. 20, Oct. 1931, pages 560-569.

The abrasion of steel due to the combined sliding and rolling action was measured in an Amsler universal wear testing machine. The method of tests is described, and it was found that for the same materials, a test piece rotating at a higher speed is less worn than one rotating at a lower speed if the contact be rolling with a slip between the contact surfaces. For 2 test pieces of different hardness, the abrasion is less if the harder sample rotates at higher speed than vice versa. If the powder produced by the abrasion is present between contact surfaces the abrasion sometimes increases as much as 100% of that where no such powder is present. The contact between rail and tire is considered in the light of the mechanism of abrasion as explained before, by assuming that the tire flange always slips on the rail. 15 references. Ha (4)

The Galvanic Behavior of a Chromium-Nickel-Iron Alloy in Sulfite Liquors. W. ANDRES WESLEY & F. L. LAQUE. *Paper Trade Journal*, Vol. 92, Apr. 2, 1931, pages 56-61.

A Cr-Ni-Fe alloy can function as cathode in galvanic couples in neutral and in acid solutions without destruction of the surface film which renders it passive in these electrolytes. Mechanical and other disturbances of the surfaces of this alloy rendered it active, at least temporarily, in which condition it behaved more nearly like Fe than like a noble metal. Fe coupled with Cr-Ni-Fe in Na_2SO_4 solution suffered just the same amount of galvanic corrosion as it did when coupled with Pt. In sulphite liquors, freshly surfaced Cr-Ni-Fe behaved erratically for a time, but always tended to become passive, to behave like a noble metal and to remain in that condition until its surface was again abraded. The behavior of couples in which a valve bronze was connected with the alloy or with Pt indicated that the corrosion process was different in tower acid from that in reclaimed acid. The test conditions were somewhat different from plant conditions in that these solutions were saturated with SO_2 at 50° and atmospheric pressure. In reclaimed acid the corrosion of valve bronze was accelerated to the same degree when it was coupled with Cr-Ni-Fe as with Pt, indicating that the corrosion process involved to a predominating extent the reaction of some depolarizing agent active in this solution. In tower acid the corrosion of valve bronze was accelerated much less by coupling it with Fe alloy than by coupling it with Pt. A similar result was obtained in pure dilute H_2SO_4 solution. The discrepancy is thought to be the result of a difference between the H overvoltages of the 2 cathode surfaces. Ha (4)

Chemical Embrittlement of Boilers. W. W. ROBINSON, JR. *Petroleum World*, Vol. 28, Feb. 1931, pages 63-67, 89, 91-93.

A series of Southern California boiler-water concentrates was subjected to analysis for total solids, NaOH, Na_2CO_3, Na_2SO_4 and pH, for the purpose of bringing out any tendency in the waters to cause embrittlement of boiler steel by the action of NaOH. Parr and Straub's ratio, Na_2SO_4 to total alkalinity as Na_2CO_3, was found to be much below the limit of safe operation. By calculating the ratio $(Na_2SO_4+Na_2CO_3)/NaOH$, that is, by recognizing Na_2CO_3 as well as Na_2SO_4, as an inhibitor of embrittlement by caustic results more in accordance with the fact that there had been no boiler failures with the water in use were obtained. When the concentration of NaOH in a water builds up to a certain level, CO_2 is reabsorbed and Na_2CO_3 is regenerated at the expense of NaOH. Hence it would be possible in some cases to control the ratio by allowing high total solids to accumulate in the water. Ha (4)

Factors Affecting the Efficiency of Cadmium Plating as a Rust Preventive. S. WERNICK. *Industrial Chemist*, Vol. 7, Sept. 1931, pages 358-361.

13 references. The function of zinc plating as a protective deposit on ferrous metal is to act as the anode of the zinc iron cell which automatically comes into action when the case metal is exposed. Doubt is expressed as to whether a cadmium deposit functions similarly as determinations of electrode potentials of cadmium and iron have variously reported anodic and cathodic relationships between these 2 metals. The factors affecting the protection attained are: (1) The nature of the base metal. In general, rolled material is to be preferred to cast, and mild steel to carbon steel. (2) The composition of the solution, and conditions of deposition. The cyanide solution is invariably used. (3) The weight of the deposit/unit area of surface. 600 mgms./dcm.,^{2} or a thickness of 0.0075 mm. is regarded as safe practice. The critical thickness, however, will vary with crystal size of the deposit. RAW (4)

Accelerated Corrosion Test, of Sprayed Molten Metal Coatings Applied on Steel, in a SO_2-CO_2-Air Atmosphere. L. PESSEL. *Proceedings American Society for Testing Materials.* Vol. 31, Pt. 2, pages 294-303, 15 figures.

A spray test of the "salt spray" type, but using water atomized by a SO_2-CO_2-air mixture, instead of brine atomized by air, was applied to a large number of metal-sprayed metallic coatings on steel. Of 23 metals and combinations of metals spray coated upon steel, all but lead were shown to give very poor results in this corrosion test. For service of the types that might be represented by the corrosion test chosen, the life of a properly applied lead coating/0.008" thick is estimated at a minimum of 2 yrs. Cadmium was worse than zinc. Steel grit blasting of steel before depositing the sprayed metal coating is preferred to sand blasting. Many of the sprayed coatings showed poor adherence. HWG (4)

Destructive Action of H_3PO_4 on Metallic Alloys. V. K. Pershke, M. P. Kapostuin & E. V. Yushmanov. *Journal Chemical Industry*, Moscow, Vol. 7, May 1, 1930, pages 875-877.

Experiments are described on the resistance of alloy cast iron and Cu alloys containing Sn, Zn, Al, Pb, Sb and Ni to the action of 84.7% H_3PO_4 at temperatures from 20°-150° C. The results are given in 3 tables. Alloys containing 78% Cu are resistant; with 63-80% Cu, they are satisfactory; but with a Cu content lower than 63%, they are not resistant to H_3PO_4. Alloys with the same Cu content and nearly equal percentages of Pb, Al and Sb show the same resistance. With the same Cu content, Ni instead of Zn and Pb, or Sn and Zn, Pb instead of Zn increases the resistance; Pb instead of Sn has no influence; Pb and Sb instead of Zn do not change the resistance of the alloy. Alloys with a high content of Pb and Zn are not resistant. Brass with a Cu content of 85-90% and Cu-Ni alloys with 80% Cu are recommended for apparatus coming in contact with concentrated H_3PO_4 at 150°. WHB (4)

The Attack of Alkaline Printing Dyes on Copper Rolls (Ueber das Angreifen der kupfernen Zeugdruckwalzen durch alkalische Drucksolen). K. Reinking & G. Bernardy (I. G. Farbenindustrie). *Melliand Textilberichte*, Vol. 12, May 1931, page 328.

Experiments were carried out with the object of throwing light on the premature failure of copper rolls used in cloth printing. EF (4)

Corrosion of Water Mains. H. R. Redington, J. L. W. Birkinbine & F. N. Speller. *Journal American Water Works Association*, Vol. 23, Nov. 1931, pages 1649-1693.

Pipe now represents from 8 to 9% of the total yearly iron and steel production, or about 11% of the finished products. Between 70 and 80 million tons of tubular products have been put into service in the last hundred years. About 75% of this amount has been made and installed in the last 20 years, and about half of this total tonnage has been used for water, oil and gas lines. The improvement in the quality of piping material has been considerably advanced by rigid specifications, covering its physical and chemical properties, its fabrication, inspection, tests, joints, coatings, etc. The theory of corrosion, its causes and preventions, are reviewed. There seems to be no question among water works engineers as to the reliability of steel, when properly protected and laid in such circumstances as the local conditions require. Protective coatings are treated in some detail, both nonmetallic and metallic. Data furnished by the Portland Cement Association indicate that properly made concrete is a practical method of defeating corrosion of both large and small pipe under very severe soil conditions. They recommend a 1-inch minimum reinforced coating made of one sand, 1½ gravel and 3 cement; and the use of 2-inch by 6-inch mesh No. 13 wire, the reinforcement being carefully placed in the center of the covering so that it will have at least one half-inch protective covering. Cement-lined and Talbot-lined pipe offer a practical means of preventing corrosion and loss of capacity due to internal incrustation or tuberculation. Talbot lining, an English development now available in this country, consists of a selected asphalt bitumen mixed with a chemically inert filler, and is applied to the inside of the pipe by the centrifugal process. The widespread adoption of industrial water softening by the Zeolite process has also completely changed the corrosion picture as regards life of pipe in the hard water districts. The manufacturers are making every effort to produce pipe material and protective coatings that will reduce the losses caused by the deteriorating effects produced by service conditions, but the great need is comparative data from many communities. WAT (4)

Corrosion Protection of Water Constructions. (Korrosionsschutz bei Wasserbauten.) A. W. Rick. *Korrosion und Metallschutz*, Vol. 7, Nov. 1931, page 278.

The author outlines the salient features of sub-aqueous protection and reviews the non-metallic coatings for preserving the surface stability of structural work under the water level. The following groups are treated separately: (1) Oil containing hard resin coatings. (2) Artificial resin lacquers and cellulose lacquers. (3) Bituminous coatings. EF (4)

Corrosion and Conservation of Underground Structures. P. J. Richards. *Journal American Water Works Association*, Vol. 23, Apr. 1931, pages 529-533.

A general discussion of soil corrosion and protection. VVK (4)

Complex Compounds of Tartaric Acid and Tri-Valent Metals (Komplexverbindungen der Weinsäure mit dreiwertigen Metallen). E. E. Wark & J. W. Wark (University of Melbourne). *Zeitschrift für physikalische Chemie*, Abt. A, Vol. 157, Nov. 1931, pages 310-314.

Among the tri-valent metals, Fe, Cr, and Sb are considered. EF (4)

Protection of Pipes in Water Works from Frost, Ice and Other Influences. (Rohrbeschädigungen bei Wasserversorgungsanlagen durch Frost, Bergschäden und andere Einflüsse.) E. Wahl. *Das Gas- und Wasserfach*, Vol. 74, Mar. 28, 1931, pages 289-293; Apr. 4, 1931, pages 311-318.

Transmission pipes 1.5 m. underground, if not carefully installed, will cause trouble due to frost. Fractures caused by the cold can be avoided if the pipe lines are placed far enough below the surface. In two cases the depth to which the frost penetrated the ground was determined by tests and observations. In mining operations the question of the depth of the piping is important for the same reasons. Fractures in pipes caused by ice formation are characterized and classified. Losses due to frost and similar influences are discussed. Cases where tubes laid in clay or loam soil graphitized were observed. MAB (4)

Corrosion in Tanks and Tankers. *Engineering*, Vol. 131, May 15, 1931, pages 643-644.

Thin Films and Corrosion. Ulick R. Evans. *Engineering*, Vol. 152, Sept. 18, 1931, page 291; *Korrosion und Metallschutz*, Vol. 7, Oct. 1931, page 249; *Foundry Trade Journal*, Vol. 45, Sept. 17, 1931, pages 173-174 and 184; Sept. 24, 1931, pages 197-198.

Abstract of paper read before the Institute of Metals, Zurich, Switzerland, Sept. 1931. See *Metals & Alloys*, Vol. 3, Jan. 1932, page MA 4. LFM + OWE (4)

Metallic Coatings as Protection Against Corrosion. (Die metallischen Ueberzüge als Korrosionsschutz.) W. H. Creutzfeldt. *Paper before the First Corrosion Congress of the Verein deutscher Ingenieure, Verein deutscher Eisenhüttenleute, Deutsche Gesellschaft für Metallkunde, Verein deutscher Chemiker*, Oct. 20, 1931, Berlin.

5 methods of making metallic coatings are discussed: (1) rolling on or soldering on, (2) diffusion at high temperature, (3) dipping in the coating metal, (4) spraying on of the liquid coating metal, (5) electrolytic depositing. There follows a discussion of coatings of Zn, Sn, Cd, Pb, Al, Cu, brass, bronze, Ni and Cr. GN (4)

Peculiar Observations During the Solution of Steel in Acids. (Eigentümliche Beobachtungen bei der Auflösung von Stahl in Säuren.) K. Daeves, E. H. Schulz & R. Stenkhoff. *Stahl und Eisen*, Vol. 51, Nov. 12, 1931, pages 1397-1402; correction, Nov. 19, 1931, page 1441.

After reviewing previous observations on the above problem, the authors report the result of their own investigations which show that the time of solution of steel is rather independent of the composition as far as C, Mn, S and P are concerned, with the exception of Cu. A special apparatus has been devised to facilitate the determination of the actual time of solution. This apparatus measures the developed gas volumes and makes it possible to accurately establish the effect of the previous treatment of the steels, such as deformation, annealing and hardening, upon the time of solution. Though many factors have their bearing upon the result of the individual determinations, it could be shown that the process according to which the steel had been made has a marked effect upon the time of solution. The results indicate that the time of solution of Thomas steel is shorter than that of open hearth steel. Whereas the time of solution of 25 samples of Thomas steel made by 4 different plants is practically alike, rather heavy fluctuations were found with 25 samples of open hearth steel made by 4 different plants. GN (4)

The Causes of Corrosion Phenomena Observed Occasionally on Stationary Oil Tanks of Aluminum. (Ueber die Ursachen der an Standölkesseln aus Aluminium gelegentlich aufgetretenen Korrosionserscheinungen.) G. Eckert. *Aluminium, Hauszeitschrift V. A. W. und Erftwerk*, Vol. 3, Sept.-Nov. 1931, pages 351-354.

Tests have shown that linseed oil, if overheated, can occasion corrosion of Al apparatus. A strict temperature supervision where linseed oil is boiled in Al vessels should therefore be exercised. Ha (4)

Fittings for Fermentation and Storage Vessels of Aluminum. (Armaturen an Aluminium-Gär -und Lagergefässen.) G. Eckert. *Aluminium, Hauszeitschrift V. A. W. und Erftwerk*, Vol. 3, Sept.-Nov. 1931, pages 354-356.

Examples of corrosion on beer tanks, caused by mercury contact and other effects, are illustrated. A joint to the discharge pipe is recommended which eliminates the trouble. Ha (4)

The MBV-Process, an Effective Surface Protection for Aluminum and its Alloys. (Das MBV-Verfahren, ein wirksames Oberflächenschutz-Verfahren für Aluminium und dessen Legierungen.) Eckert. *Aluminium Hauszeitschrift V. A. W. und Erftwerk*, Vol. 3, Sept.-Nov. 1931, pages 349-351.

By treating Al wares in an aqueous solution of 5% calcined soda and 1.5% sodium-chromate for 3 to 5 min. at 90°-100° C. a protective film has been formed which will stand bending and rolling to a certain extent. The layer resists beer, gin, sour milk, soap solutions and other liquids used in making artificial silk. Acids and alkalis destroy the layer. Ha (4)

Influence of the Shaping and Riveting of Structural Iron on Corrosion. (Einfluss der Formgebung und Nietung von Konstruktionseisen auf die Korrosion.) V. Duffek. *Korrosion und Metallschutz*, Vol. 7, Nov. 1931, pages 275-277.

The paper presented before the Reichsausschuss für Metallschutz, May 1931, reports on corrosion experiments in tap and sea water carried out with the object of studying the relation of the corrosion attack to the shape of the samples tested and to the influence of rivets respectively. The experimental work is performed in the Duffek corrosion apparatus, which represents an accelerated corrosion testing method. (24 hours, 120 mm. constant O_2 pressure). A more pronounced corrosion attack was noticed in the regions around the rivets. A protective effect of the rolling scale, which was not removed, could be established. One set of specimens was submitted to an annealing treatment. However the resulting oxide scale did not display a marked corrosion protection as was distinctly the case with the scale produced by rolling. An increased corrosion attack was noticed when the corrosion products were not removed from the surface. In contrast with Evans' theory the author found that horizontal planes with a surface directed downwards hardly showed any corrosion attack, whereas the top surface of the horizontal areas were strongly corroded. The author connects this phenomenon with the corrosion products which inhibit the depolarization of the hydrogen. The iron absorbs the hydrogen and assumes a less noble potential which results in an accelerated solution of the metal. Based on his observations, the writer urges construction engineers to avoid horizontal areas and to provide for means for a flowing off of the corrosion products. EF (4)

Corrosion of Gas Plant Equipment. B. G. Dick. *Gas Age-Record*, Vol. 66, Sept. 20, 1930, pages 433-436, 442; *Western Gas*, Vol. 7, Aug. 1931, pages 66-73.

Part of Report of Committee on Corrosion of Gas Plant Equipment of the Pacific Coast Gas Association. Corrosion of metal roofs, gutters and downspouts, holder cups, oxide purifiers, smoke scrubbers, steel brick lined waste heat boiler flues, reciprocating pump valves and parts exposed to the atmosphere. Metallography & Macrography (5a)

On the Ternary System Iron-Nickel-Phosphorus (Ueber das ternäre System Eisen-Nickel-Phosphor). R. VOGEL & H. BAUR. *Archiv für Eisenhüttenwesen,* Vol. 5, Nov. 1931, pages 269-278.

Report from the Metallographic Laboratory of the Institute of Physical-Chemistry at the University of Göttingen. 10 references. The complete ternary diagram was established for the concentration range Fe-Ni-Ni_3P-Fe_3P, i.e., for the Fe-Ni alloys containing up to 15% P, by studying the cooling conditions of 8 concentration sections. In the field of the alloys containing a higher percentage of P, the features of the equilibria between the 4 phosphides Fe_3P, Ni_3P, Ni_5P_2 and Fe_2P were determined. The results show that ternary phosphides do not exist within the concentration range examined. Fe_3P and Ni_3P form a complete range of solid solutions without miscibility gap. The Fe-rich members of these solid solutions correspond to the meteoric "Schreibersit." In the concentration range Fe_3P-Ni_3P-Ni there exists a 4-phase transitory equilibrium between melt, P and Ni bearing α-and γ-solid solutions and the solid solutions of Ni_3P and Fe_3P (Schreibersit). The equilibrium temperature is 970° C. Between the above 3 crystal phases exists a ternary miscibility gap. The transformations of the ternary Fe-P-Ni solid solutions are of a very complicated nature, due to the following reasons: (1) The changes of solubility are of a peculiar nature because of the recurrence of the α-γ-transformation in the system Fe-P; that means the alignment of the γ-field in connection with the widening of the γ-field in the system Fe-Ni, which occurrences totally correspond to the conditions in the system Fe-P-C. (2) The other reason is that the ternary miscibility gap narrows at lower temperatures as regards the α-γ-solubility but widens as regards the solubility of "Schreibersit"; i.e., occurrences of crystallization and re-solutions of a various nature take place simultaneously. GN (5a)

Further Studies on Chromium-Nickel-Iron and Related Alloys. V. S. KRIVOBOK, *et al. Mining & Metallurgical Investigations Bulletin* 103, 1931, 40 pages.

The constitutional diagram of Cr-Ni-Fe was theoretically investigated with respect to factors influencing the existence of metastable phases and the so-called decomposition or disintegration of these alloys. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 251. Ha (5a)

The Phase Diagram of the System Iron-Zirconium. (Das Zustandsschaubild Eisen-Zirkon.) RUDOLF VOGEL & WILLI TONN. *Archiv fur das Eisenhüttenwesen,* Vol. 5, Jan. 1932, pages 387-389.

Complete phase diagram of the system Fe-Zr is given, as developed on basis of cooling curves and structure investigations. Fe and Zr form a compound Fe_3Zr_2, fusion point 1640° C. δ-iron dissolves 7% Zr in formation of mixed crystals. The δ-γ-transformation results in a so-called "second fusion point." Solubility of Zr in γ-Fe at 1330° C. amounts to 0.7%, and in dissociation of γ-mixed crystals at 830° C. solubility in α-iron decreases to 0.3% Zr. β-Zr also forms mixed crystals with Fe, which upon solidification are saturated with 5% Fe. Due to the transformation of Zr, solubility at 1000° C. in α-Zr is increased to roughly 10% Fe. Pure electrolytic Fe, and Zr, obtained by decomposition of the iodide, were used. Zr contained only traces of Si, Hf and W. To make the low Zr alloys, the Zr was added in form of small pieces of sheet to molten Fe, while for the rich alloys small Fe and Zr rods were heated together. A vigorous reaction shown by a bright flaring up of the mixture took place between Fe and Zr far below fusion point of Fe. With alloys of more than 25% Zr, temperatures became so high that they could no longer be measured with a noble metal thermocouple (Pt = Pt-Rh). Samples were all melted under argon, due to energetic reaction with N, O, H, and CO at high temperatures. Fusion temperature of pure Zr assumed from Zwikker and De Boer's work to be 1857° C. Structure diagrams of 3%, 10%, and 40% Zr-alloys are given. GN + DTR (5a)

Transformation of White into Gray Tin (Ueber die Umwandlung von weissem in graues Zinn). G. TAMMANN & K. L. DREYER. *Zeitschrift für anorganische und allgemeine Chemie,* Vol. 199, July 8, 1931, pages 97-108.

The speed of the transformation of white into gray Sn was determined by measuring the growth of the diameters of the "warts" formed when rolled strips of white Sn are inoculated with gray Sn in contact with $(NH_4)_2SnCl_6$ solution. The speed varies directly as the time, passes through a maximum at -30° C., diminishes with increase in grain size, and is slightly dependent on the orientation of the grain. Polishing with emery decreases the speed appreciably, though irregularly. Cold working increases the speed. Impurities, especially Zn, Cd, Cu, Ag, Pb, Bi and Sb interfere with the change. Addition of 0.5% of Bi or Sb prevents the formation of gray Sn. Bi is more effective than Sb, for the Sb-Sn alloys tend to darken. When test pieces carrying warts of gray Sn are heated to 100° C. to restore the white form and then cooled to -10° C., the speed of the transformation was increased, the increment diminishing with the time of heating. Carbon and Iron. (Kohlenstoff und Eisen.) *Metallbörse,* Vol. 21, May 23, 1931, pages 963-964; May 30, 1931, pages 1011-1012; June 6, 1931, pages 1059-1060.

A review of the phenomena in the C-Fe system and of the historical development of its diagram. WHB (5a)

Study of the Systems Cu-Be, Cu-Si, Ag-Si, Ag-Be, Au-Be, Au-Si, by Cementation (Quelques résultats obtenus par la méthode de cémentatio sur les couples de métaux, Cu Gl, Cu Si, Ag Si, Ag Gl, Au Gl, Au Si). L. LOSKIEWICZ, *Congres International des Mines, de la Métallurgie et de la Géologie appliquée, Section de Métallurgie,* 6th session, Liege, June 1930, pages 535-545. 11 references.

By heating the various metal pairs in contact and study of metallography and scratch hardness of the diffusion zones, an attempt was made to verify the correctness of the various equilibrium diagrams that have been suggested for these pairs. The hitherto unexplored Au-Be diagram appears to be of the same type as that for Au-Si. Neither of these diagrams may be as simple as that for Au-Si has been supposed to be. The work was only preliminary. Brief comment is made on attempts to get alloying by cementation with other metal pairs. B and Ag apparently alloy. HWG (5a)

Preliminary Report on the Structure of Quenched Steel. G. KURDUMOFF & I. EVENSEN. *Journal of Physical Chemistry,* Russia, Vol. 1, Issue 1, 1930; *Transactions State Physical-Technical Laboratory* No. 14, U.S.S.R.

All the data available at the present time led the authors to believe that martensite is a metastable solid solution of carbon in α iron. The following main structures of steel quenched with different cooling velocities and possessing a great hardness may be expected. (1) Tetragonal lattice having a definite axial ratio for a given carbon content. (2) Not uniform tetragonal lattice. (3) Cubic lattice. In order to check this supposition the following experiments were carried out by the authors. Specimens $60 \times 8 \times 6$ mm.^{3} were quenched in water. One end only was immersed in the water, the other part of the specimen remaining in the air. The steel investigated contained 1.04% C. The surface layer 1.5-2 mm. thick of the quenched specimen was removed. The specimens were etched in 2% alcoholic nitric acid. The macrostructure revealed 3 zones which were attacked differently by the etching reagent. The first zone was that portion of the specimen which was immersed in the water and also that part which was located slightly above the water line. It was etched slowly and uniformly. The second zone, next to the first, was etched more readily and not uniformly. The third zone was etched most rapidly. Microscopic examination revealed that the first and second zones possessed a characteristic needle-like martensitic structure. At the upper part of the second zone the dark troostitic structure was also observed; the amount of troostite is increased with the approach toward the third zone, the structure of which was entirely troostitic. The X-ray examination showed that there were austenitic lines in the first zone and that lattice was tetragonal. The austenitic lines were observed in the first and second zones. It was also observed that these lines were shifted in different directions with respect to the α iron lines. This shift gradually decreased with the approach toward the third zone. At the end of the second zone, the sharp α iron lines began to appear. These lines were superimposed upon the wide martensitic lines. There was a mixture of the cubic martensite, austenite and troostite. In the third zone there were observed only the sharp lines of α iron and the lines of Fe_3C. There was a very small change of the Herbert hardness in the first and second zones. A pronounced change in hardness was observed at the end of the second zone and this change was smaller in the third zone. For different quenching conditions, different crystal structures of martensite may be obtained. Martensite possessing the characteristic needle-like structure and great hardness is obtained when the rate of quenching is such that Ar″ point is present. A tetragonal structure is obtained when quenching is very drastic. Therefore this structure may be regarded as the first step of disintegration of austenite when disintegration begins at Ar″ point. It may be stated at the present time that the tetragonal structure represents the solid solution in which the iron atoms are arranged in the body centered and greatly distorted tetragonal lattice, the carbon atoms being arranged between the iron atoms. The disintegration of the tetragonal structure we may consider as the second step of disintegration of austenite. The transformation of tetragonal lattice to cubic is accomplished by means of a gradual decrease of axial ratios. The authors' observations seem to show that martensite possessing the cubic lattice, the parameter of which is different from that of α iron cannot be obtained and they believe that in cases when such phenomenon was discovered the lattice really was ununiform tetragonal but not cubic. AIK (5a)

The System Silver-Copper-Manganese (Das System Silber-Kupfer-Mangan). M. KEINERT. *Zeitschrift für physikalische Chemie,* Abt. A, Vol. 156, No. 4, Oct. 1931, pages 291-303.

This ternary system has been investigated carefully. It was found that, in the liquid state, segregation does not occur in alloys with less than 30% Mn. All alloys with more than 80% Ag show primary Cu and Mn containing Ag crystals in an eutectic of these crystals with Cu-Mn solid solutions. The saturation limit passes from a content of 9% Cu to a content of 20% Mn. The hardness and other mechanical properties of the alloy in the range of the saturation content of the Ag crystals can be influenced to a great extent by heat treatment so that a refining process is possible. Ha (5a)

Constitution and Formation of the Phosphide Eutectic in Cast Iron (Die Konstitution und Bildung des Phosphideutektikums im Gusseisen). M. KUENKELE. *Giesserei mit Giesserei-Zeitung,* Vol. 18, Jan. 23, 1931, pgs. 73-78; Jan. 30, 1931, pgs. 94-98.

A new etching method which distinguishes between cementite and phosphide better than picric acid is described. See *Metals & Alloys,* Vol. 1, Dec. 1930, page 906. Ha (5a)

The Constitution of the Alloys of Copper, Zinc and Tin. *Metallurgist,* Oct. 1931, pages 154-156.

An extended abstract of a paper by O. Bauer & M. Hansen in *Zeitschrift für Metallkunde,* Vol. 22, Dec. 1930, pages 405-411. These authors, taking the work of Hudson and Jones on 47 alloys (*Journal Institute of Metals,* Vol. 14, 1915, page 98) as a basis, investigated 31 additional alloys. The system was investigated by means of thermal analysis and the study of the micro-structure of annealed and quenched specimens. See *Metals & Alloys,* Vol. 2, Nov. 1931, page 250. VVK (5a)

Structure & X-Ray Analysis (5b)

The Development of Coarse-Structure Examination of Metallic Materials by X-Rays (Die Entwicklung der Roentgen-Grobstrukturuntersuchungen metallischer Werkstoffe). Part I. H. Reininger. *Giesserei mit Giesserei Zeitung*, Vol. 18, Aug. 28, 1931, pages 681-685.

The development and application of practical X-ray examination of the coarse structure of metals as existing today in different countries is described and discussed exhaustively. A comparison of the most important industrial countries shows a pronounced advance for America in the practical utilization while, with respect to apparatus and testing technique and the multiplicity of research, hardly a difference between the different countries could be observed. In this first installment, the development of Germany is treated in detail. 35 references. Ha (5b)

High Chromium Steels, Carbides and Inclusions. A. Westgren (Stockholm, Sweden). *Metal Progress*, Vol. 20, Nov. 1931, pages 57-61.

The author discusses X-ray and metallographic studies of Fe-Cr-C system which show 4 carbide constituents; cementite in which a number of the iron atoms are replaced by chromium atoms, the face centered cubic carbide Cr_4C, the trigonal Cr_7C_3, and the orthorhombic Cr_3C_2; in each of these, Cr atoms may be replaced by iron atoms. The peritectic nature of these alloys is discussed. The existence of a eutectic of the cubic carbide and Cr is shown. The identity of the small and large carbide aggregates in ball bearing steel is shown. The utility of the X-ray method in the study of phase identification together with the microscope is discussed. WLC (5b)

Utilization of Resonance Forces for Calculating Molecular Spacings (Abschätzung von Molekülgitterabständen aus Resonanzkräften). E. Cremer & M Polanyi (Kaiser Wilhelm Institut für Chemie, Berlin-Dahlem). *Zeitschrift für physikalische Chemie*, Abt. B, Vol. 14, Nov. 1931, pages 435-442.

The resonance forces are derived from optical data and the distances of some planes of elementary molecular space lattices are calculated. EF (5b)

X-Rays in a Boiler Shop. Chas. O. Herb. *Machinery*, Vol. 37, Jan. 1931, pages 334-337.

An installation for routine inspection by a non-destructive method of fusion welds in high-pressure boilers and tanks is described. Ha (5b)

X-Ray Investigation of the System Sulphur-Selenium. II. The Space-Lattice of the Monoclinic Selenium. I. Modification (Röntgenographische Untersuchungen im System Schwefel-Selen. II. Raumgitter des monoklinen Selens. I. Modifikation). F. Halla, F. X. Bosch & E. Mehl. (Technische Hochschule Wien). *Zeitschrift für physikalische Chemie*, Sect. B, Vol. 11, Feb. 1931, pages 455-463.

Crystals of monoclinic Se, first modification, according to Groth, were investigated by X-ray methods, the results of which are in agreement with previous publications concerning all properties except color. The simplest elementary body includes 32 Se-atoms and has the following constants: $a' = 11.50$ A.U., $b' = 8.98$ A.U., $c' = 8.977$ A.U., $b = 90° 57'$. Aiming at the simplest arrangement, a molecular space lattice is given; the crystal molecule consists of 8 atoms. There seems to be a quadruple arrangement forming a bi-molecular racemate. See *Metals & Alloys*, Vol. 2, Oct. 1931, page 211. EF (5b)

Advances of Transportable X-Ray Testing Equipment. (Weiterentwicklung Fahrbarer Röntgenprüfanlagen.) A. Herr. *Die Wärme*, Vol. 54, Apr. 25, 1931, page 332.

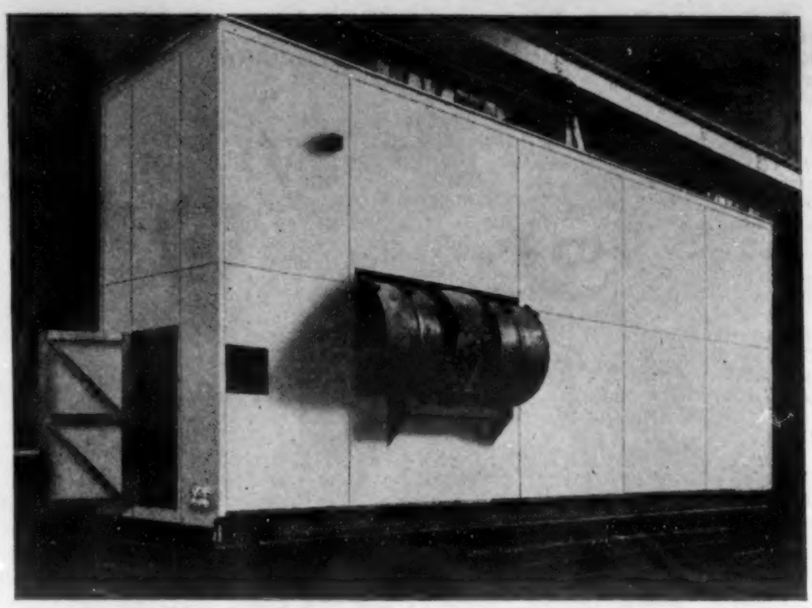
The difficulties involved in the utilization of X-ray testing equipment mounted on a truck are critically discussed and the recent developments of the German State Railroad and the German Navy are considered. The trend is mainly characterized by the possibility of easily taking to pieces the whole installation. The 2 illustrations included in the article refer to (a) the transportable "Material Isolux Röntgenanlage," System Seifert, type vertical arrangement, 180 kv./20 m Amps pulsating DC tension and (b) to the horizontal design of the same company, the data of which are as follows: 200 kv./15 m Amps pulsating DC voltage. EF (5b)

The Intensity of Quartet Lines in the Arc Spectrum of Copper. C. W. Allen. *Physical Review*, Vol. 39, Jan. 1, 1932, pages 54-63.

Intensity measurements in the arc spectrum of copper have been made for the quartets $a^4D' - c^4D$, $a^4F - c^4D$, and $a^4P - c^4D$, by using an electric arc at atmospheric pressure, and currents ranging from 1 to 19 amperes. It has been shown that the lines of these quartets may be divided into 2 groups, (1) those with initial terms $c^4D_{1,4}$ (sharp lines) and (2) those with initial terms $c^4D_{2,3}$ (broad lines), such that within each group the intensity relation of the lines remains practically constant for all current strengths. In comparison with group (1), however, the lines of group (2) increase their intensity rapidly with current strength up to about 12 amperes, beyond which they remain constant. The intensities approach nearer to the sum rule predictions for currents over 12 amperes, but even then there are some deviations. Nevertheless the similarity between the observed and calculated values supports the accuracy of the line classifications. WAT (5b)

Broad Lines in the Arc Spectrum of Copper. C. W. Allen. *Physical Review*, Vol. 39, Jan. 1, 1932, pages 42-54.

Attention is called to the anomalous broadening behavior of certain lines in the copper arc spectrum. Breadths of several lines have been measured with copper arc spectra and pressures up to 80 atmospheres. The following are the most essential conclusions: (1) broad lines with the same initial term have the same breadth; (2) all lines show a linear increase in breadth with increasing pressure; (3) lines arising from $c^4D_{2,3}$ terms have a considerable breadth at zero pressure. The discussion touches on the nature and cause of the breadth of some of the copper lines; it is concluded that the breadth is an inner property of the copper atom, that is, not due to external disturbances. The effective diameter of the copper atom would need to be increased considerably by excitation if the pressure broadening is to be accounted for by the Lorentz collision effect. WAT (5b)



Defects in Riveted Joints of Boiler Drums and their Location by Means of X-Rays. (Schäden an Nietverbindungen von Kesseltrommeln und ihre Feststellung mit Hilfe von Röntgenstrahlen.) C. F. Franzen, R. Berthold & W. Kolb. *Die Wärme*, Vol. 54, Nov. 14, 1931, pages 843-848.

The defects occurring at the riveted joints of a water tube boiler are described. In addition to the conventional investigation methods, i.e. inspection of the rivet holes, pressure test according to Stehr, etc., the X-ray examination offers a safe method of revealing defects. The potentiality and the testing equipment employed are discussed. EF (5b)

The Physics of Solids and Fluids. P. P. Ewald, T. Pöschl & L. Prandtl. Translated by J. Dougall & W. M. Deans. Blackie & Son, London, 1930. Cloth, 6x9½ inches, 372 pages. Price $6.00.

Translation of articles by the 3 authors which appeared in the 11th edition of Müller-Pouillets Lehrbuch der Physik. The sections by Pöschl (elasticity and strength of materials and friction of solid bodies, 76 pages), and by Prandtl (equilibrium and flow of liquids and gases, 203 pages) follow the usual lines of text books on mechanics and aerodynamics.

The section by Ewald (mechanical structure of solids from the atomic standpoint, 72 pages) is of the most interest to the metallurgist. It is an attempt to connect atomic properties and the properties of matter in bulk. Atomic forces and lattice energy are studied in respect to thermal expansion, thermal and electrical conductivity, compressibility, etc., the mechanics of crystal surfaces are considered, and Smekal's "weak places" in crystals are discussed. The evidence is so contradictory and ideas are so chaotic that even qualitative explanations can seldom be given.

Ewald starts his discussion of single crystals by saying, "Of the play of forces which retain the atoms of a metal in their places in the lattice, we know next to nothing." Slip, or gliding, in single crystals is discussed, and the conclusion drawn that "the technical problems of strength may gradually become accessible to the methods of theoretical physics."

The production of fibrous structure, or crystal orientation, upon working a polycrystalline material is discussed, along lines of Wever's "pole-figures," and the conclusion is that this is an extremely complicated process which has been much studied without anything more than qualitative relations having been found.

The question whether there is a finite elastic limit remains unanswered.

Ewald says that if he were asked to give a perfectly honest reply to the question how far modern physics has gone in explanation of the actual mechanical behavior of solids, he would reply that the first steps have been taken along a new road that may lead further than the old ones, but that a general theory of state for metals is still a long way off though it is the only possible foundation for a theory of strength. Even the processes in single crystals are far from easy to understand, and the further step to polycrystalline material will also be difficult.

The impression one gets from Ewald's frank discussion is that the theoretical physicist is still groping in a dense fog, and that he will continue for a long time to be baffled in his attempt to find the answers to the questions of metallurgy he is seeking to solve. H. W. Gillett (5b)-B-

Preferred Orientation Produced by Cold Rolling in the Surface of Sheets of Aluminum, Copper and Silver. C. B. Hollabaugh & W. P. Davey. (Pennsylvania State College). *Metals & Alloys*, Vol. 2, Oct. 1931, pages 246-250; Nov. 1931, pages 302-312.

49 references. In cold working a metal, the crystals fail by shear along the crystallographic planes of the largest interplanar spacing. For face centered metals considered, this failure is along the (111) family of planes as confirmed experimentally on single crystals of Al. A sheet of metal is composed in the cast or annealed condition of many crystals of continuous orientation within themselves; the sheet itself represents many orientations. On cold working, the crystal fragments have a tendency to orient themselves in preferred orientations. Metals of the same lattice shearing along the same planes should assure the same preferred orientation if no other factor enters. The other factor of possible influence is the atomic forces holding the metal in its lattice. The variety of chemical properties represented by face centered metals suggests that these forces may vary considerably. Recent work has shown that the assumption that metals of the same lattice assume the same preferred orientation is erroneous. This paper presents the results of a study of the orientation assumed by several face centered metals under the same condition of working. By use of the reflection type of defraction, only one surface is examined. The data obtained shows not a single preferred position but a range which is not the same in each case. Ni and Cu show identical limits of range and mean position in their preferred orientation. Al and Ag show related orientations but widely different angular limits dependent, in the case of Al, on the number of passes through the rolls but independent of this variable in the case of Ag. The preferred positions of all are similar only in that one face diagonal of the cube is parallel to the direction of rolling and perpendicular to the rolling surface. The similarity is consistent with their identical face centered cubic arrangement and the differences and similarities in other respects are consistent with their chemical valence. Cu and Ni, of the same valence and atomic numbers 29 and 28, respectively, show marked similarity. Al, with a valence of 3 and atomic number of 13, is markedly different from Ag with a valence of 1 and atomic number of 47 and both are different from Cu and Ni. A comprehensive review is made of the literature on the subject. The experimental technique of making the X-ray examination, the annealing and rolling treatment of the samples are described in detail. The difference in preferred orientation is discussed in the light of the chemical properties of the individual metals. Al is shown to be very sensitive to rolling conditions while the other 5 metals are comparatively insensitive to increasing number of passes. WLC (5b)

Recent Progress in Testing of Materials by X-Rays with Special Regard to Completely Built-in Boilers and Apparatus (Die neueren Fortschritte in der Material-Röntgenuntersuchung unter besonderer Berücksichtigung von fertig eingebauten Kesseln und Apparaten). A. Herr. *Schmelzschweissung*, Vol. 10, Nov. 1931, pages 258-262.

It is noted that, for very valuable objects, the X-ray investigation should not be restricted to the finished product but should start during the early manufacturing process. This will often save very expensive repairs while the testing in earlier stages requires only a negligible outlay. The safety of operation, economy, reliability of X-ray testing as applied with modern apparatus is discussed and illustrated by many examples. 10 references. Ha (5b)

X-Ray Analysis of the Copper-Silicon Alloys (Röntgenanalyse der Kupfer-Silizium Legierungen). S. Arrhenius & A. Westgren (University of Stockholm.) *Zeitschrift für physikalische Chemie*, Sect. B, Vol. 14, No. 1, 1931, pages 66-79.

The constitutional binary diagram Cu-Si was re-established by means of an X-ray investigation (powder method, Fe-K radiation). One set of the alloys was quenched in water from a temperature just below the melting point, while a second set of samples was drawn at 550° C. The experiments disclosed the existence of 5 different intermediate phases, 2 of which ($\beta + \delta$) are only stable at elevated temperatures; 2 of which ($\gamma + \epsilon$) are only stable at ordinary temperature; while η forms on solidification and remains stable down to room temperature. The following statements on the various phases are given: (1) β, hexagonal close-packed atomic arrangement, 14.5 atomic %-Si, $a_1 = 2.588$ A.U., $a_3 = 4.176$ A.U., $\frac{a_3}{a_1} = 1.633$. (2) γ, same structure as β-Mn, 17 atomic % Si, parameter = 6.210 A.U., 20 atoms in the unit cell, formula Cu_5Si. (3) δ with 18 atomic % Si has probably the same structure as deformed γ-brass (4) ϵ with 21 atomic % Si belongs to the body centered cubic atomic arrangement; parameter = 9.694 A.U., number of atoms in the unit cell: 76; formula: $Cu_{15}Si_4$. (5) η contains 25 atomic % Si, hexagonal arrangement similar to the cubic type of β brass. The space lattice dimensions are subject to only small changes due to varying concentrations within the ranges of homogeneity. The authors compare their constitutional diagram with the latest one proposed by C. S. Smith (Transactions A.I.M.M.E., 1929, page 414). EF (5b)

X-Ray Crystal Analysis. *Engineer*, Vol. 152, Sept. 25, 1931, page 326.

Editorial commenting on a publication of the Department of Scientific and Industrial Research by Sir William Bragg. Regrets that report does not deal sufficiently with problems of practical importance to the engineer. LFM (5b)

X-Ray Application to Wire and Wire Products. N. P. Goss. *Wire & Wire Products*, Vol. 6, June 1931, pages 217, 219.

A brief treatise on the manner in which the metallurgical engineer may conclude from diffraction patterns made with X-rays on the presence of certain atomic structural arrangements which indicate physical characteristics not suitable for the purpose for which the material is intended. Incoherent Scattering of X-radiation. (Über die inkohärente Streuung von Röntgenstrahlen.) W. Heisenberg (University of Leipzig) *Physikalische Zeitschrift*, Vol. 32, Oct. 1, 1931, pages 737-740.

The writer applies the methods of Thomas and Fermi to derive an equation for the incoherent scattering of X-rays. EF (5b)

Incoherent Scattering of X-radiation. (Über inkohärente Streuung von Röntgenstrahlen.) L. Bewilogua (University of Leipzig) *Physikalische Zeitschrift*, Vol. 32, Oct. 1, 1931, pages 740-744.

The article pertains to a discussion of Heisenberg's equation for incoherent scattering of X-rays (see abstract above) and arrives at the conclusion that the effect of incoherent scattering is only a small fraction of the total except at high angles and with light atoms. EF (5b)

X-ray Examinations in Industrial Plants. (Röntgenuntersuchungen im Werkstättenbetrieb.) C. Kantner & A. Herr. *Metallwirtschaft*, Vol. 10, Sept. 11, 1931, pages 717-720.

Contains 5 references. Examination of metals by penetration with X-rays has become especially useful in the field of welding. The quality of welding has been considerably improved and confidence of engineers in the reliability of properly made welds has been increased. Recently X-ray examination of welds made on steel buildings and bridges has been carried out at the locations, instead of in the laboratory only, as formerly. In general visual examination is sufficient and photographs are necessary only in special cases. Methods of shielding certain surfaces with sheet Pb so that the images of several welds do not overlap are described. A telescopic device has been developed, by which hollow bodies and tubes can be examined indirectly, not in the line of the X-rays. The image can also be magnified in the same device. It was found that when welded test pieces which showed porous spots in the weld were broken in a tensile machine, the fracture started not in the porous spot but in the concentric layers around the porous spot. CEM (5b)

The X-Ray Determination of Elastic Stresses in Bent Crystals. (Die röntgenographische Bestimmung elastischer Spannungen in gebogenen Kristallen.) S. Konobejewski & I. Mirer. (Institute of Non-Ferrous Metals, X-ray Department, Moscow.) *Zeitschrift für Kristallographie*, Vol. 81, Jan. 1932, pages 69-91.

The principal results of the investigation are: (1) Laue patterns of bent rock salt and gypsum crystals show asterism due to the elastic deformation of the space lattice. (2) According to the Laue pattern a re-bending of the rock salt crystal in its original position also straightens the lattice. (3) In recrystallization the bent lattice lamellae disintegrate to small fragments; the original lattice does not reappear upon re-bending. (4) A method is described to calculate the elastic stresses from the X-ray pattern. (5) By designing and evaluating the stereographic projections the elastic stresses were determined to amount to about 83,900 lbs./in.² 10 references. GN (5b)

PHYSICAL, MECHANICAL & MAGNETIC TESTING (6)

Some Tests on the Magnetic Secondary Effects (Einige Versuche über die magnetische Nachwirkung). H. Kühlewein, *Physikalische Zeitschrift,* Vol. 32, June 15, 1931, pages 472-480.

The occurrence of retardation disturbances was observed in some kind of relays incorporating highly permeable alloys. Two methods were developed for determining the time curve of magnetization. Experiments were carried out on pure permalloy (78.5% Ni, 21.5% Fe), in the annealed state and after slowly cooling (40% Ni, 60% Fe) in the same two states; Perminvar (35% Ni, 25% Fe, 30% Co) after slowly cooling and charcoal iron after the same treatment. Only Permalloy exhibited pronounced magnetic secondary effects in the tested frequency range. The rest of the paper relates to experiments with the Helmholtz pendulum on the slope of the time/induction curve with reference to Permalloy, Permalloy containing 1.5% Si, 40% Ni, 60% Fe and charcoal iron after various treatments. Gain in Strength by Preliminary Stress (Materialverfestigung durch Vorspannung). E. Kressig. *Glasers Annalen,* Vol. 55, Nov. 1, 1931, pages 77-80; Nov. 15, 1931, pages 85-88.

Formulae covering the stress of material are developed, based on the hypothesis of elongation, and used for evaluating the strain hardening effect of preliminary stresses. EF (6)

The Deformation of Metals under Prolonged Loading. D. Hanson & M. A. Wheeler. *Engineering,* Vol. 132, July 10, 1931, pages 56-58; July 24, 1931, pages 120-122.

Condensed from paper read before the Institute of Metals, March 12, 1931. See *Metals & Alloys,* Vol. 2, Aug. 1931, page 144. LFM (6)

Magneto-elastic Phenomena in Relation to the Elastic Limit (I fenomeni magneto-elastici in relazione al limite di elasticita). G. Guzzoni & D. Faggiani. *La Metallurgia Italiana,* Vol. 23, Nov. 1931, pages 1029-1045.

Magnetic tests were carried out on hard drawn and annealed wires of 0.09% and 0.85% C steel; on 0.09% C, 0.12% Ni; 0.36% C, 2.04% Ni; 0.24% C, 2.92% Ni; 0.16% C, 4.28% Ni and on Invar, A.M.F., and Permax alloys, 0.03% C, 35.03% Ni; 0.10% C, 45.20% Ni; 0.03% C, 76.12% Ni, with the wires under different tensile stresses. The elastic limit as ordinarily determined does not coincide with any particular variation in magnetic induction. The "elastic limit," as usually determined, is higher than the stress producing the beginning of permanent deformation. The curves of induction do not allow detection of the beginning of plastic flow. Contains 13 references, 13 figures, 18 tables. HWG (6)

Flow Tests on Steel Tubes under Combined Pulling and Torsion Stress. (Fliess versuche an Rohren aus Stahl bei kombinierter Zug- und Torsionsbeanspruchung). K. Hohenemser (University of Göttingen) *Zeitschrift für angewandte Mathematik und Mechanik,* Vol. 11, Feb. 1931, pages 15-19.

Experiments were performed with the Losenhauser Testing Machine (max. pulling capacity = 15,000 kg. and torsion moments of 15,000 kg./cm.) on open hearth steel with 0.08% C and 0.5% Mn after annealing at 950° C. The results are in accordance with the Hencky equations on flow, but did not verify the Reuhs Theory. In addition to the flow in metals during constant stress, states are encountered in which, although the stresses are approaching the yield point, an unequivocal relationship exists between stress and elongation. EF (6)

Load Tests with Cylindrical Steel Helical Springs. (Belastungsversuch mit zylindrischen Schraubenfedern aus Stahl.) Max Ensslin. *Maschinenbau,* Vol. 10, Aug. 6, 1931, pages 496-500; Aug. 20, 1931, pages 536-540.

The article presents a method for calculating the strength of helical springs by tensile, pressure and torsion tests. The influence of much overloading of the spring before usage, the influence of recoil, and the behavior of cold rolled springs with and without supplementary heat treatment, is investigated. The twenty cylindrical helical springs tested have, under tensile or pressure loads, a shear elasticity modulus of G = 772,000 to 879,000 kg./cm.[2] The range and upper limit is greater than for structural steel. Determination of the usual spring load is made by means of the modulus of the same spring. MAB (6)

Hardness Testing by Measurement of the Depth of Penetration. (Die Harteprüfung mit Tiefenmessung.) O. Dettinger. *Maschinenbau,* Vol. 10, Jan. 1, 1931, pages 14-18.

Tests were carried out on unhardened carbon steels. Two modifications of the new portable Brinell machine are described. A ball of 2.5 mm. diameter and with a load of 187.5 kg. was used. The loading was effected by a system of springs. A curve was made by which the depth of the impression can be read directly in the apparatus. The possibility of determining the tensile strength by comparison with the Brinell number is discussed. MAB (6)

On the Interpretation of Some Ferromagnetic Phenomena. Francis Bitter. *Physical Review,* Vol. 38, Jan. 1932, pages 337-345.

A paper in the Symposium on Ferromagnetism of the American Physical Society, Sept. 1931. During these first years of the twentieth century our knowledge of ferromagnetism has made great progress. We have learned empirically how to make those magnetic materials which are the foundation of the countless electrical circuits woven around the earth. Instruments have been built to work equally well under most varied conditions. Materials are available that will respond to the enormous forces produced by generators in power stations, to the faint current signal produced by sounds thousands of miles away. We are beginning to learn something of the mechanisms which are responsible for the existence of ferromagnetism and for the various phenomena associated with it. Starting with the conception that magnetic materials are made up of atomic magnets in thermal interaction, and that magnetization results from their reorientation, the paper outlines our present knowledge of ferromagnetism, and indicates a few places along the above lines where progress is to be expected. WAT (6)

Dynamic Fracture Tests on Airplane Framework. (Dynamische Bruchversuche mit Flugzeugbauteilen). H. Hertel. *Zeitschrift für Flugtechnik und Motorluftschiffahrt,* Vol. 22, Aug. 14, 1931, pages 465-474; Aug. 28, 1931, pages 489-502.

Testing devices and procedures developed by the Deutschen Versuchsanstalt für Luftfahrt for testing the vibration strength of airplane spars, with and without static loads, are described. 10 metal spars and spar parts, consisting of welded and riveted steel spars, steel spar framework, and duralumin spar framework, as well as 2 wooden spars, were tested up to fracture. The wooden spars displayed no reduction in the durability of the spar flange, compared with that of the working materials on the test stand. The durability for the metal spar, on the contrary, amounted to only a fraction of the value expected from the durability points of the working materials, because a local tension increase appeared which amounted to a multiple of the average tension fixed in the calculation. The good results obtained with wooden spars were at the fixed cross-sectional parts, and stress arrangements and glued joints were satisfactorily reduced for the working material. The unsatisfactory results with metal spars are shown in the detrimental increase of tension at the rough cross-sectional parts (butt straps and gusset plates), in the single and double riveting, and in the detrimental effect of machining on the properties of the working materials used in the construction. WAT + WHB (6)

Some Notes on the Alternating Bend Test for Thin Mild Steel Sheets. J. C. Godsell (Swansea Municipal Technical College). *Sheet Metal Industries,* Vol. 4, Mar. 1931, pages 936-937.

Paper before Swansea Technical College Metallurgical Society. The work was an investigation of the influence of some factors on the Jenkins bend test. Length and width of strip tested were found to have no effect on the values obtained as were speed of testing, and additional pressure on the roller. Direction of test with respect to direction of rolling altered the values. The value of the radius vector for any given angle may be calculated from the formula

$$n\Theta = \sqrt{n^2_0 \operatorname{Cos}^2\Theta + n^2_{90} \operatorname{Sin}^2\Theta}$$

where n = number of bends and 0°, 90°, and Θ = inclination of test strips to direction of rolling. AWM (6)

Hardness Tests on Chilled Castings. (Die Prüfung der Härte von Schalenhartguss). O. Heune. *Der Papier-Fabrikant,* Vol. 29, Apr. 19, 1931, pages 244-249.

Experiments were carried out to investigate the sources of error involved in the Brinell hardness test on chilled castings. The deviation of the indentation mark from the circular form is stated to be responsible for the irregular measuring results. The occurrence of cracks at the edges of the ball impressions and the kind of balls used were furthermore found to exert an influence. The performance of at least 3 determinations is suggested. A deviation of more than 1% of the average hardness value is not generally to be expected. A further source of error, not due to the Brinell hardness testing method, but due to the round surface of the chilled castings is pointed out. In summary, it may be stated, that the Brinell method can be used successfully for testing chilled castings. EF (6)

On the Measurement of the Resistance of Shield Plates to Penetration by a Rifle Bullet. K. Honda, G. Takemae & T. Watanable. *Kinzoku no Kenkyu,* Dec. 1931, pages 619-632 (In Japanese); *Science Reports Tohoku Imperial University,* Vol. 19, pages 703-725 (In English).

An investigation was carried out to measure quantitatively the efficiency of a shield plate in resisting penetration by a rifle bullet. A steel specimen was set at the front of a large sand box suspended from a ceiling frame as a ballistic pendulum. Since the displacement of the sand box caused by the impact of the rifle bullet is small, it was magnified by a device similar to that used in a seismograph. The residual velocity of the bullet after passing through a test plate was obtained from the displacement of the sand box. A so-called "characteristic curve" showing the shielding efficiency of a metal was obtained for different metals and alloys. The curve not only gives the residual velocity of a bullet after passing through a shield plate of a given thickness, but also the thickness of the metal plate which is just sufficient to stop the impinging bullet, or the "penetration distance." The best material found as the result of the investigation is a special steel, the penetration distance of which is 4.5 mm. for a bullet 9 g. in mass and of a velocity 790 m./sec. An effective material for resisting penetration by a bullet must possess a great hardness combined with toughness. In the case of plain carbon steel and other metals, great hardness is always combined with brittleness, so that a good material for an effective shield plate must be sought for in special steels. The most effective material found by the investigation is a heat-treated special steel, which with a thickness of 4.5 mm. completely stops a bullet 9 g. in mass and 790 m./sec. in velocity. A single plate is more effective than a laminated plate of equivalent thickness. Two plates of equal thickness separated from each other by a distance are more effective than a single plate of equivalent thickness; the effect of separation is greater as the distance increases. TM (6)

Measuring the Magnetic Saturation (Zur Messung der magnetischen Sättigung). E. Gerold. *Archiv für Eisenhüttenwesen,* Vol. 5, Nov. 1931, pages 267-268.

In using the apparatus of Gumlich, a relation can be established which permits the calculation, with sufficient accuracy, of the magnetic saturation at a certain field strength when one value of induction has been measured. When, in magnetizing with a current of 1 ampere the induction, B has been found and the saturation is then calculated according to the normal graphic method of Gumlich to be $4\pi I_\infty$, the equation holds true: $4\pi I_\infty = B_{1A} \times 1.018 - 5400$. Many time-consuming measurements can thus be avoided. 4 references. GN (6)

The Testing of Strip Copper and Copper Alloys. Maurice Cook & E. C. Larke. *Metal Stampings,* Vol. 4, Nov. 1931, pages 897-898, 926.

The physical testing of thin strips for specified work by tensile, hardness and cupping tests is discussed. See *Metals & Alloys,* Vol. 2, Dec. 1931, page 306. Ha (6)

On the Transverse Effect of the Magneto-striction. (Ueber den Quereffekt der Magnetostriktion.) G. Dietsch & W. Fricke (University of Jena). *Physikalische Zeitschrift,* Vol. 32, Aug. 15, 1931, page 640.

The transverse effect of the magneto-striction, i.e. the cross section changes of ferro-magnetic poly-crystalline material in magnetic fields was studied by 2 testing methods developed in the Physikalisches Institute of the University of Jena. A short description of the methods, the sensitivity of which amount to 10^{-8} cm., and a characteristic testing curve gained on vacuum melted electrolytic iron are presented. EF (6)

On the Transverse Effect of the Magneto-striction. (Ueber den Quereffekt der Magnetostriktion.) A. Esau (University of Jena). *Physikalische Zeitschrift,* Vol. 32, June 15, 1931, pages 483-485.

The transverse effect of the magnetostriction (see abstract above) is computed for soft iron, Ni, Co and Ni steel containing 29, 36 and 46% Ni. EF (6)

The Yield Point and Initial Stages of Plastic Strain in Mild Steel Subjected to Uniform and Non-Uniform Stress Distributions. Gilbert Cook. *Transactions Royal Society of London,* Vol. 230, 1931, pages 103-147.

The paper describes an investigation carried out to determine for mild steel, (1) the relation between the stress at the yield point in simple tension and in the non-uniform distribution produced by torsion, flexure, and internal pressure in a hollow cylinder, and (2) the stress distribution in each of the latter cases in the early stages of overstrain. Apparatus is described for obtaining load-deformation diagrams in which the true resistance to deformation during overstrain is measured. Those obtained for the non-uniform distribution are compared with theoretical diagrams based upon the assumption that a specific shear stress causes the initial breakdown, and that the initial stages of plastic strain take place at a uniform, but lower, shear stress. It is shown that the maximum shear stress at the initial yield point is consistently higher in the non-uniform distribution than in uniform tension. In the cylinders a pronounced scale effect was observed. All the results are consistent with the supposition that the initial dislocation resulting in elastic breakdown takes place at a critical value of the shear stress at a certain depth in the material, in other words, that a surface layer exists possessing the same elastic properties as, but higher elastic limit than, the interior. In the initial stages of overstrain, the load-deformation diagrams follow closely the theoretical shape, and confirm the assumption that a lower stress exists in the overstrained parts than is required to initiate the yielding process. The author suggests that the stress reduction is a consequence of variations in load from one crystal grain to another. Irreversible and discontinuous displacements occurring either at the crystal boundary or in the interior of the crystal, which are associated with the process of slip, are regarded as affording relief to the reversible elastic distortion in the same crystal, the amount of relief depending upon the magnitude of the individual displacements. WAT (6)

Influence of the Velocity of Deformation on the Deformation Resistance. (Einfluss der Verformungsgeschwindigkeit auf den Verformungswiderstand.) W. Tafel & E. Viehweger. *Zeitschrift Verein Deutscher Ingenieure,* Vol. 75, Dec. 5, 1931, pages 1479-1483.

A series of static and dynamic tests for determining the dependency of the average flow limit upon the velocity of deforming is described and the formula of Fink used for the calculation of the dynamic stresses. A relation is found between the static and dynamic stresses which can be expressed by $\delta_{dyn} = 2V_m + \delta_{m\ stat} + \Delta\,\delta$. The tests lead the authors to the conclusion that the official regulations for riveting steels should be revised by defining the exact upsetting temperature and number of blows. Ha (6)

New Methods and Results of Elasticity and Sound Velocity Measurements in Solid and Molten Metals. (Ueber neuere Methoden und Ergebnisse der Elastizitäts-und Schallgeschwindigkeitsmessungen in festen und geschmolzenen Metallen.) O. Stierstadt. *Metallwirtschaft,* Vol. 11, Jan. 8, 1932, pages 18-21; Jan. 15, pages 32-34.

Contains 12 references. The velocity of sound through metal is measured by attaching two microphones to the metal rod at different distances from the end where the source of sound is placed. If each microphone is connected to an earphone the sound will reach the two ears at different intervals. By inserting a direction compensator and adjusting it so that the sound from the two microphones reaches the ears at the same instant, the velocity of the sound can be calculated. Molten metals are placed in a tube and the velocity is determined in a similar manner. Measurements on several metals proved that the velocity through the solid metal is very nearly two times the velocity through the molten metal. Bi is an exception, the velocity through the solid metal being lower. By a series of mathematical deductions the author gives relationships between the sound velocity, compressibility, modulus of elasticity and specific heat of solid and liquid metals. CEM (6)

Physical Testing During the Assembling of Boiler Water Tubes, Pipe Lines and Fittings. (Bauüberwachung von Kesselsiederohren, Rohrleitungen und Armaturen.) H. Stehr. *Die Wärme,* Vol. 54, Apr. 25, 1931, pages 309-311.

The technique of carrying out the different bending tests on tubes for boiler systems are discussed and illustrated. The lecture was delivered at the Zentralverband der Preussischen Dampfkessel Überwachungsvereine, 1931. EF (6)

Testing of Tubes and Super-heater Pipes. (Abnahme von Rohren und Überhitzer-schlangen.) R. Schnabel. *Die Wärme,* Vol. 54, Apr. 25, 1931, pages 309-311. Sonderheft "Werkstoff und Herstellung in neuzeitlichen Dampfkesselbau."

The different manufacturing methods of seamless boiler water tubes, the sources of trouble in the manufacturing processes, the traditional testing methods for the material in the as-received state are fully dealt with in this paper which was presented before the Zentralverband der Preussischen Dampfkessel Überwachungsvereine, 1931. EF (6)

Investigation of the Influence of Heat Treatment of Structural Steel on Its Behavior in a Drilling Test. (Versuche über den Einfluss der Wärmebehandlung von Baustahl auf sein Verhalten beim Bohrversuch.) W. Schwinning & G. Gutberlet. *Maschinenbau*, Vol. 10, Mar. 5, 1931, pages 178-183.

Tests were made on five structural steels (St 37, St 48, St 52, VCN 35 and an unalloyed tool steel). The effect of a systematic variation in structure obtained by gradual annealing on the machinability was made on tool steel chips. The mechanical properties of the heat-treated material (hardness, tensile strength, elastic limit, elongation, reduction of area, notch impact strength) were determined and compared as a means of explaining the relationship between the structure and behavior in the drilling test. MAB (6)

Notes on the Hardness Testing of Metals. *Sheet Metal Industries*, Vol. 5, July 1931, page 236; Sept. 1931, pages 352, 357, 358; Oct. 1931, pages 431-432, 437.

From a pamphlet issued by Wild-Barfield Electric Furnaces Ltd., Elecfurn Works, North Road, Halloway, N 7. The introduction points out that the Vickers method will be dealt with and shows the fallacy of a spherical indenter in that the relation between diameter and surface area of 2 unequal impressions will not be the same. Then, since diameter alone is measured, it follows that the readings will be fallacious. The diameter of impression in Brinell testing which yields the ideal is taken as being ⅜ the diameter of the ball. The angle of the Vickers pyramidal diamond is 136° which is the angle arrived at by subtending the tangents of the extremities of the ideal ball impression. A test to verify the accuracy of the Vickers test is outlined. Errors of the ball indenter are given as, its spherical form and distortion of the indenter, while the diamond indenter is not subject to deformation at normal loads. The area of impression is in direct proportion to the hardness with a given load. The hardness reading will be the same and strictly in accordance with the Brinell equation $\frac{\text{load}}{\text{area}}$, irrespective of load. The accuracy of the Vickers method and the ease of reading the diagonal of the impression obtained are discussed. The cost of maintenance is set at \$4-5 for relapping the diamond. This is necessary at intervals varying from 6 mo. to 2 yrs. depending on the materials tested. AWM (6)

A "Magnetic Sharpener." L. W. McKeehan. *Physics*, Vol. 1, Dec. 1931, pages 388-392.

The research was carried out at Yale University. The claim that the mere placing of a double-edged safety razor blade upon the poles of a permanent magnetic of special design has a sharpening action has been investigated by studying the characteristics of the device and by testing the sharpness of blades so treated in comparison with untreated and with mechanically stropped blades. No definite "magnetic sharpening" was observed to occur in these tests. The method of measuring the sharpness was similar to that used by Honda and Takahasi (Scientific Reports Tohoku Imperial University, Vol. 1, No. 16, 1927, pages 755-773). The blade, mounted vertically in a brass block with cutting edge horizontal, was drawn slowly to and fro across a stack of paper strips clamped on a metal base. The paper was a good grade of condenser paper about 0.0013 cm. thick. The number of pieces of paper cut in a given number of strokes was a measure of the sharpness. There is positive evidence that mechanical stropping helps in maintaining a fair degree of sharpness. A conspicuous feature of these data is the wide difference which may exist between properties of edges intended by manufacturers to be alike, that is, the edges of a single blade. This makes generalization from a few cases particularly dangerous, but the effect of treatment in the "magnetic sharpener" is less beneficial than advertising claims in such phrases as these: "An instantaneous, automatic sharpener, in which a powerful magnetic takes the place of all stropping, honing or crank-turning" — "the strong magnetic of the amazing sharpener instantly draws the bent 'teeth' into straight and true alignment — restoring factory keenness absolutely." Extravagant statements like these, if untrue, can only diminish the confidence of the general public in better-founded claims presented for inventions in which physical principles are correctly applied. WAT (6)

Apparatus for Measuring Elongation. (Messgeräte für Dehnungsmessungen.) Ernst Lehr. *Maschinenbau*, Vol. 10, Dec. 3, 1931, pages 711-725.

Includes 57 references. The constructor must, if he wishes to build with the least expense and yet safely, recognize the fact that stresses will occur in the structures, and he must know where they are distributed. This knowledge can be obtained only by means of elongation measurements. Static elongation measurements will serve to determine the spatial distribution of stresses in the structure and particularly to locate the extent of the strains and the time of load. The apparatus which have been accepted for carrying out such measurements is described in the article. MAB (6)

Changes in the Dimensions of Metallic Wires Produced by Torsion. II. Silver, Gold, Aluminum and Nickel. III. Lead. Thomas Lonsdale. *Philosophical Magazine and Journal of Science.* Series 7, Vol. 11, June 1931, pages 1169-1196.

The papers give the measurements of the changes in lengths of the metals named in the form of wires when they are twisted at room temperature. Considerable elongations are produced by twisting even under very small tensions. Five references. Ha (6)

International Testing Congress Discusses Impact and Cast Iron. Correspondence from A. Portevin, Paris, France. *Metal Progress*, Vol. 21, Feb. 1932, pages 67-68.

Test Results and Service Values of Materials. H. F. Moore. *Lecture at joint meeting American Society for Testing Materials and American Institute of Mining & Metallurgical Engineers*, Feb. 18, 1932, Advance Copy, 7 pages. Mimeographed.

Making of accurate tests and deciding what they mean in terms of service are 2 different things. Ductility tests are ordinarily taken as showing service value, but it is difficult to conceive of a structure which can utilize more than 5% deformation without failing to function. Good tests are needed to indicate ability to withstand spreading of a crack under repeated stress and to defeat high localized stress. All accelerated corrosion tests are regarded as of doubtful reliability. Impact tests on notched bars were developed without knowledge that they measure important qualities, but rather because they were easy to make and because it seemed reasonable that a material with high resistance in the test must be able to stand punishment in service. Comparison of service results is tending to establish the test as a valuable one. Delicate proportional limit determinations do not appear to measure as important service properties as do tests with greater plastic deformation as the criterion. Attention is called to the proposed new A. S. T. M. definition of yield strength and methods for determining it. Endurance limit data are valuable in respect to machine parts, but not to most structures. The test should be correlated with the service. Tests for creep at high temperatures give promise as of great engineering significance. HWG (6f)

Tables of Elastic Properties of Alloys. C. H. Kent. *University of Nevada Bulletin*, Vol. 23, No. 6, Oct. 1, 1929; *Engineering Experiment Station Bulletin* No. 2, 55 pages. Price 20c.

This is a compilation of data from various American sources. It could well have been extended to include foreign data. The individual references from which the data are taken are not given so the user will often have difficulty in checking back to the original source for more complete information. This is the main drawback of the compilation. The term "elastic properties" as here used is a broad one; special attention is given to tabulation of endurance properties of various steels and non-ferrous alloys. Considerable attention is paid to high temperature properties of metals and heat-resistant alloys, but since these data are chiefly of the 1910 to 1924 vintage, they are not particularly valuable. There are data on C steels, S.A.E. steels, Mo steels, Ni steels and cast irons, Si steels, bearing metals, die casting alloys, Cu-Be alloys, etc. The only original material is found in the brief introductions to the various sections. These are good, that to the section on endurance being especially to the point. On the whole, the compilation is a useful one. HWG (6f)

Contribution to the Problem of Fatigue of Metals. (Zur Problemstellung der Metallermüdung.) W. Kuntze. *Metallwirtschaft*, Vol. 10, Nov. 27, 1931, pages 895-897.

Contains 13 references. The author attempts to prove that there is no disagreement between himself and Sachs-Laute in their theories on fatigue of metals, especially in regard to strengthening by understressing. He shows graphically that the fracture by repeated alternating stress is always at the intersection of the tensile strength line and the resistance to change in shape line. It is not a case of strengthening during the first cycles and a tendency toward fracture during later cycles, but both occur at the same time with the tendency to fracture outweighing the strengthening. Understressing functions first to increase tensile strength and, second, to reduce disintegration. The endurance limit is higher than the endurance yield point by an amount proportional to the understressing capacity. The formula,

$$\text{endurance limit} = \text{endurance yield point} \times \frac{\text{tensile strength of unstressed material}}{\text{tensile strength of material stressed to initial fracture}}$$

has been checked by numerous tests on various materials. However, the endurance yield point disappears when the number of cycles increases beyond the point where the material loses its plasticity. CEM (6f)

The Static and Fatigue Properties of Brass. J. B. Kommers. *Proceedings American Society for Testing Materials*, Vol. 31, Pt. 2, 1931, pages 243-258.

Includes discussion. See *Metals & Alloys*, Vol. 2, Oct. 1931, page 215. HWG (6f)

Nickel Tubing Resists Fatigue. R. Worthington. *Automotive Industries*, Vol. 66, Jan. 30, 1932, page 164.

Stress-cycle endurance curves, to 100 million cycles, are shown, as determined at Wright Field, for tubing. These show:

Material	Elongation % in 2 in.	Endurance Limit 100 Million Cycles lbs./in.^{2}
Hard drawn Ni, surface ground	9½	42,000
Annealed Ni, surface ground	48½	29,000
Hard drawn Cu, surface as drawn	4	22,000
Annealed Cu, surface as drawn	56	12,000

Vibration tests at higher stresses place the materials in the same order as do the endurance tests. Annealing of airplane fuel line tubing does not produce improved resistance against repeated stress. Annealed Ni tubing is suggested for this use as it combines ease of bending with good endurance limit. The article contains a good discussion of the significance of short-time bend tests as compared with long-time fatigue tests. HWG (6f)

ELECTRO-CHEMISTRY (7)

Electrochemistry of Magnesium (Zur Elektrochemie des Magnesiums). SVEN BRODFORSS. *Zeitschrift für physikalische Chemie,* Vol. 153, Feb. 1931, pages 83-106.

The change of potential of a Mg-electrode with time was determined in $MgSO_4$ and $MgCl_2$ solutions. The effect of varying the acid content and varying the buffer in the presence of neutral salts and NH_4 salts or of hydroquinone, resorcinol succinimide, phrocatechol, CO, CO_2 and H_2 was determined. Mg becomes less noble as the pH concentration of the solution is increased, till a maximum is reached. This is explained by the reaction Mg $\rightleftarrows$ (ion) + e or 2Mg $\rightleftarrows$ Mg_2 (ion) + $2e$. Ha (7)

Theory of the Velocity of Diffusion of Strong Electrolytes in Dilute Solution. G. S. HARTLEY. *London, Edinburgh & Dublin Philosophical Magazine & Journal of Science,* Series 7, Vol. 12, Aug. 1931, pages 473-488.

The paper considers the diffusion velocity of strong electrolytes in the light of the activity function and derives a theory based on a uniform pressure acting on any elementary layer of the liquid which is equal to the difference of the osmotic pressure at the 2 surfaces of the layer. Additional forces are exerted on the ions because of the gradient of electrical potential. 17 references. Ha (7)

Oversaturation Phenomena during the Electro-Deposition of Metals (Ueberschreitungserscheinungen bei der elektrolytischen Metallabscheidung). T. ERDEY-GRUZ & M. VOLMER (Technische Hochschule, Berlin). *Zeitschrift für physikalische Chemie,* Abt. A, Vol. 157, Nov. 1931, pages 182-187.

Irregularities in current-voltage curves plotted during the electro-deposition of metals upon indifferent electrodes of foreign carrier materials are ascribed to over-saturation phenomena. The metals experimented with are Cd, Pb, Bi, Cu, and Ag which were deposited on electrodes of Pt, Ta, Au and, in some cases on C. EF (7)

A new method of electro-depositing polonium and the radio-active isotopes of bismuth (radium E and thorium C) on platinum electrodes loaded with hydrogen is given and the advantages of the deposition on a noble metal carrier are pointed out. EF (7)

Electrolytic Over-Voltages on Metals (Zur Frage der elektrolytischen Metallüberspannung). T. ERDEY-GRUZ & M. VOLMER (Technische Hochschule, Berlin). *Zeitschrift für physikalische Chemie,* Abt. A, Vol. 157, Nov. 1931, pages 165-181.

The investigators carried out experiments with the object of clearing up the phenomena connected with the chemical polarization, or the metal over-voltage as designated by the authors. EF (7)

The Deposition Potentials of Nickel (Die Abscheidungspotentiale des Nickels). F. FOERSTER & K. GEORGI (Technische Hochschule, Dresden). *Zeitschrift für physikalische Chemie,* Bodenstein Festband, 1931, pages 453-467.

When electro-depositing the metals of the iron group from the solutions of their simple salts, a strong polarization effect occurs at the cathode. The logarithmic course of the current-density/potential curves disclosed the reaction to be a "checked" one. Recent investigation of Gladstone (*Journal Chemical Society,* London, 1926, page 2887) on the polarization phenomena led to the conclusion that the Ni-deposition only starts at a definite equilibrium potential materially different from the cathode-potential and thence, without any retardation. The authors present evidence to prove theoretically and experimentally that Gladstone's assumptions are erroneous. EF (7)

Electrochemistry, Principles and Practice. C. J. BROCKMAN. Van Nostrand, New York, 1931. Cloth, 6 x 9½ inches, 348 pages. Price $4.00.

This is one of a series of "Industrial Chemical Monographs." The preface states that the volume is aimed to present electrochemistry in not too technical a fashion, to "the chemist, plant manager and the fringe of business men who are not adepts with electrochemical manipulations; yet it is to be hoped that the scientific value of the work will not be lost to the virtuosi of electrochemistry." The volume turns out to be a rather elementary text book of the usual type, with the usual brief descriptions of processes, cells, furnaces, etc., and very little reference to principles. Little distinction is made between successful processes and those that are obsolete, and while the bulk of the information naturally is correct, not all of it may safely be taken as such. Plating or electro-winning of Cu, Ni, Zn, Cr, Pb, Sn, Fe, Cd, Co, Ag, Au, Al, Mg, Na, Ca, Ce, Be has attention under electrolysis, and the usual topics on per-salts Cl, NaOCl, $NaClO_3$, O_3, NO_2, on primary and secondary batteries, on CaC_2, SiC, graphite, Al_2O_3, CS_2, P, Zn by distillation are covered, and brief comments made on furnaces for steel and brass. Ferro alloy manufacture is not touched upon. Copious references only partly redeem the book from the charge of giving each topic too brief treatment to be sufficiently informative. For example, the section of phosphorous and phosphoric acid tells next to nothing, although it states that "concentrated fertilizers are gaining more notoriety each year." It is stated that the size of electric furnaces may increase now that the Söderberg electrode is developed, but no inkling is given as to what the electrode is like. In reference to large furnaces, it is said that the "40 ton furnace unit contains 4 separate 3-phase circuits which do not seem to get mixed up by stray current circuits." On the whole, it is a mediocre book from every point of view, but may serve as an introduction to the subject. H. W. Gillett (7) -B-

Industrial Electrochemistry. C. L. MANTELL. McGraw-Hill Book Co., New York, 1931. Cloth, 6 x 9½ inches, 528 pages. Price $5.00.

A text book for chemical engineering courses, designed also as a work of reference. The principles of electrolysis are given in 60 pages. Hydrogen ion concentration and chemical reactions, such as preparation of per-salts, are next discussed, the electrolytic theory of corrosion is given 4 pages, electro-osmose and cataphoresis, 6. Then follow brief discussions of primary and secondary batteries and rectifiers.

Electroplating, refining, forming and winning receive more extended treatment, 110 pages. Good balance is maintained, the older processes such as nickel plating and copper refining and the newer ones such as chromium plating and the winning of zinc being treated at about the same length. The electrolysis of alkali halides and the production of hydrogen and oxygen complete the discussion of aqueous electrochemistry. The electrolysis of fused salts covers 150 pages, dealing with Al, Mg, Be, Na, Ca, Li, Ce and with Pb alloys. Electrothermics has 85 pages, dealing with metal melting, ferro alloys, carbide and cyanamid, SiC, fused Al_2O_3, and SiO_2, graphite, CS_2, H_3PO_4 and P. The discussion of electric iron-smelting furnaces usually found in treatises on electrothermics is absent, presumably as of too little interest, under American conditions, to deserve space. While many defunct types of steel and brass-melting furnaces are mentioned briefly, care is taken to indicate which ones are obsolete or practically so. On the other hand, high-frequency melting scarcely seems to get as much space as its importance deserves. The section on steel and brass melting and that on ferro alloys is more of a description of furnaces than of the high-temperature chemistry made possible by the furnaces. The metallurgist would have welcomed, and a text book of chemical engineering might well have contained, some discussion of acid and basic electric steel slag practice, for example, but the author confines his chemistry to more simple cases. The reader will hardly gather that electric steel foundry practice is essentially acid practice. Silicon as a reducer in ferro-alloy smelting is casually mentioned, but its importance not brought out. The refining step in the production of low carbon ferro-alloys is scarcely dealt with. The metallurgy of the book is somewhat skimped, and few references to important literature along metallurgical lines are included, though well-selected references are given on some other branches of electrochemistry.

Electrical discharges in gases, electronics, electrostatic precipitation, ozone and nitrogen fixation are briefly treated, as are materials of construction for electrolytic and electrothermic apparatus (electrodes receiving most attention), power generation and economics. The book ends with the usual tables. To condense so much into so little space, to give so much accurate and up-to-date information and so little near mis-information from ill-advised brief side comments that are only half-truths, is quite an achievement. It is decidedly above the usual text-book level. One would have liked to see fuller treatment of principles, especially in the metallurgical sections, even at the expense of space devoted to description of equipment, but perhaps that had better be made the subject of another book, for which there is still room. H. W. Gillett (7)-B-

Electroplating (7a)

Chromium Plating. (Cromatura elettrolitica.) O. MACCHIA. Ulrico Hoepli, Milan, 1932. Paper, 6⅛ x 9½ inches, 483 pages. Price 50 Lira.

A very complete exposition of the subject, profusely illustrated. Many of the illustrations are from American sources, and for both theory and practice, constant reference is made to the writings of Sargent, Blum and Schneidewind. One gathers that Macchia finds the basis for successful commercial chromium plating fully covered in the work of Sargent and of Blum, even though others have alleged that these were laboratory workers only. The history of Cr plating, the properties of the coating, suitable plating baths, analytical and control methods for the solution, current efficiency, bath conductivity, limits for bright plating, throwing power, testing of deposits, discussion of the theory involved, the dangers to health and their avoidance, anodes, and equipment and technique for commercial plating are all discussed in detail. Abstracts of some 190 technical articles and patents are included. The book is thoroughly indexed. A large table showing thickness of deposit per hour at various current efficiencies and current densities is included. The book is decidedly up to date, and probably more complete than any other so far published between a single pair of covers. Although it is in Italian, anyone knowing something about chromium plating and having a reading knowledge of Spanish or French can make it out fairly readily with occasional reference to an Italian dictionary. Most of the important information is elsewhere available in English, but scattered. It is collected here into convenient compass.

H. W. Gillett (7a) -B-

Theory of Chromium Deposition. R. J. PIERSOL. *Metal Cleaning & Finishing,* Vol. 3, Mar. 1931, pages 207-214.

The electrophysics of the ionic currents in chromic acid and the effects of osmotic pressure on the cathode and anode in the chromium solution are explained and compared with previous theories. The substance of the theory of chromium plating as offered by the author is that the chromium products formed by the partial reduction of chromic acid are insoluble and, therefore, do not decompose into ions. They may combine with chromic acid to form colloidal chromium dichromate, $Cr(HCrO_4)_3$, which is not ionized, either. The addition of sulphuric acid permits its chemical reaction with chromium dichromate under formation of $Cr_2(SO_4)_3$, and the liberation of the chromate radical. The chromic sulphate, being soluble, ionized into chromic, Cr^{III} ions and sulphate ions. With the formation of free chromic ions, the deposition of chromium is exactly analogous to other metals which decompose initially into a metal ion. Ha (7a)

Electrodeposition of Iron, Copper and Nickel Alloys. LAWRENCE E. STOUT & CHARLES L. FAUST. *Preprint, Transactions Electrochemical Society,* Vol. 61, Apr. 1932, pages 1-22.

The cathode process in the electrodeposition of Cu-Fe-Ni alloys from the cyanide bath is controlled by the metal and hydrogen overvoltages, both of which depend upon the concentration polarization of the solution as indicated by the rule of mixtures, which states that in an electrolyte containing a common ion, the degree of dissociation depends solely upon the concentration of the common ion and is independent of all unlike ions. This explains the inhibitive effect upon the ionization of Cu^{+}, Fe^{++}, Ni^{++}, etc., from their complex cyanides by the presence of one with another, and also by the presence of free KCN or NaCN. This inhibitive effect upon ionization, together with a variation in the initial concentration of the salts in solution, raises the over-voltage of each metal sufficiently high to be near each other in value so that a simultaneous deposition of the metals is obtained in the form of an alloy. The degree of dissociation of various metal ions in a mixture of their salts, according to the established rule, is determined by the product of the valences of the 2 ions in solution, wherein those salts of lower valence product have greater dissociation. Hence, in a mixture of complex cyanides of Cu, Fe and Ni, which dissociate in the following manner:

$$K_3Cu(CN)_4 \rightleftarrows 3K^{+} + Cu(CN)_4^{\equiv} \rightleftarrows Cu^{+} + 4(CN)^{-}$$
$$K_2Ni(CN)_4 \rightleftarrows 2K^{+} + Ni(CN)_4^{=} \rightleftarrows Ni^{++} + 4(CN)^{-}$$
$$K_4Fe(CN)_6 \rightleftarrows 4K^{+} + Fe(CN)_6^{\equiv} \rightleftarrows Fe^{++} + 6(CN)^{-}$$

would equally favor ionization of $Cu+$ and $Ni++$ at the expense of $Fe++$. In actual plating, however, the Cu deposits more readily than Ni, because of a secondary reaction at the cathode:

$$Ni(CN)_4^{=} \rightleftarrows Ni^{++} + 4(CN)^{-}$$
$$Ni^{++} + (CN)^{-} \rightleftarrows NiCN^{+}$$
$$2NiCN^{+} + 3\theta \rightarrow Ni + NiCN + (CN)^{-}$$
$$NiCN + 2KCN \rightarrow K_2Ni(CN)_3$$

which interferes with Ni deposition. The presence of tartrate as a buffer in the complex cyanide bath is essential to Fe deposition. Extensive experiment work with sulphate bath as well as cyanide bath variously buffed with tartrates, boro-tartrates, citrates and boro-citrates, verifies the view that deposition of Cu, Fe and Ni occurs from the cyanides and not from the tartrates of these metals; even if the complex tartrates were initially present, they would have been replaced by the complex cyanides. LCP (7a)

Tests for Quality of Electroplates. C. L. MANTELL. *Metal Cleaning & Finishing,* Vol. 3, Mar. 1931, pages 189-192, 203-204.

3 kinds of tests are made to determine the quality of electroplated deposits: (1) the specimen is tested for porosity to determine the number of pinholes and cracks in the plating; (2) accelerated tests for corrosion resistance and wear are applied; (3) service tests on service panels are made. The value of these methods is discussed. 7 references. Ha (7a)

Problems in High Current Density Nickel and Chromium Deposition. N. R. LABAN. *Metal Industry,* London, Vol. 39, July 17, 1931, pages 63-64; discussion, July 31, 1931, pages 110-112.

From paper given before the Electroplaters and Depositors Technical Society. Etching of basis metal is necessary for good adhesion of Ni deposit. For Ni, Cu, steels, etc., use anodic sulphuric acid etching, but for brasses use nitric acid. Peculiar to high current density work are (1) inclusions of foreign matter in deposit, overcome by depolarized anodes and good filtering; (2) lack of throwing power, overcome by increasing estimated plating time; (3) contact resistance, reduced by use of spring clips and jigs. The same difficulties are encountered in Cr plating, which shows the faults immediately. Articles which have "missed" should be anodically etched and repolished before re-chrome plating.

A New Method for the Hydrogen-Ion Control of Electroplating Solutions. I. LAIRD NEWELL. *Brass World,* Vol. 28, Jan. 1932, pages 1-2.

A simply constructed inexpensive apparatus sufficiently accurate for plating control is described. The apparatus consists of a slide comparator and a burette similarly supported. The comparator slide of bakelite contains the color standards corresponding with given pH value. The base contains a slot in which the slide can be moved back and forth and holes for the vials of indicator solution, and comparator tubes. WHB (7a)

New Ways to Surface Refining. (Neue Wege der Oberflächenveredelung.) K. ALTMANNSBERGER. *Oberflächentechnik,* Vol. 9, Jan. 19, 1932, page 14.

A few prescriptions are given to obtain decorative effects on electroplated surfaces; on Cr plated surfaces mat and glossy areas and change of the bluish-white tinge of this metal; an electrolytic method to obtain a yellowish hue of silver plating; a method of mat-pickling of brass and then Ni-plating. Ha (7a)

The Present Status of Plating on Zinc. E. A. ANDERSON. *Metal Cleaning & Finishing,* Vol. 3, Feb. 1931, page 101-104.

A complete description of the electrodeposition of Ni and Cr on Zn as it is often employed for die castings and the treatment of Zn. Solutions for cleaning are given. A good nickel bath is the following: water, 1 gal.; single nickel salts, 10 oz.; anhydrous sodium sulphate, 15 oz.; ammonium chloride 1.75 oz.; boric acid, 2 oz. No method for producing bright chromium coatings directly on Zn is known at present. Ha (7a)

Experimental Plating Cell. T. F. HAWLEY. *Metal Industry,* New York, Vol. 29, Nov. 1931, page 480.

For use in preliminary studies of regular plating procedure, such as control of current density, strength of solution, effect of temperature, an experimental plating cell can be easily made from 3 pieces of paraffined poplar board which form the sides and bottom and the two ends are formed by clamping in place metallic electrodes using rubber gaskets.

Layout of a Small Electro Zincing Department. JOHN L. EVERHART. *Metal Industry,* New York, Vol. 29, Dec. 1931, pages 527-528.

A general description is given of the arrangement of a plant for zinc plating 150 dozen yokes and 80 lbs. ferrules per day. PRK (7a)

METALLIC COATINGS OTHER THAN ELECTROPLATING (8)

Metal-Lined Steel Tubing Made by New Process. *Brass World,* Vol. 27, July 1931, page 160.

Steel tubing lined with various non-ferrous metals suitable for a variety of uses is made by the Detroit Seamless Steel Tube Co., Detroit, Mich. A metal-lined tube is supplied with a very perfect bond between the outer and inner shells, showing no evidence of possible separation. The centrifugal casting of the lining metal provides a superior texture. Linings already successfully applied are bronze, brass, Sn, and almost any alloy or non-ferrous metal. WHB (8)

Status of the Welded-On Overlay. M. CATLIN SMITH. *Steel,* Vol. 88, June 18, 1931, pages 39-42.

A review of the development of hard-facing or welded-on overlay by means of electric or acetylene heating; good prospect is seen for this process. Ha (8)

Surface Treatment of Materials. (Oberflächenbehandlung der Werkstoffe.) W. WIEDERHOLT. *Maschinenbau,* Vol. 10, Feb. 19, 1931, pages 132-134.

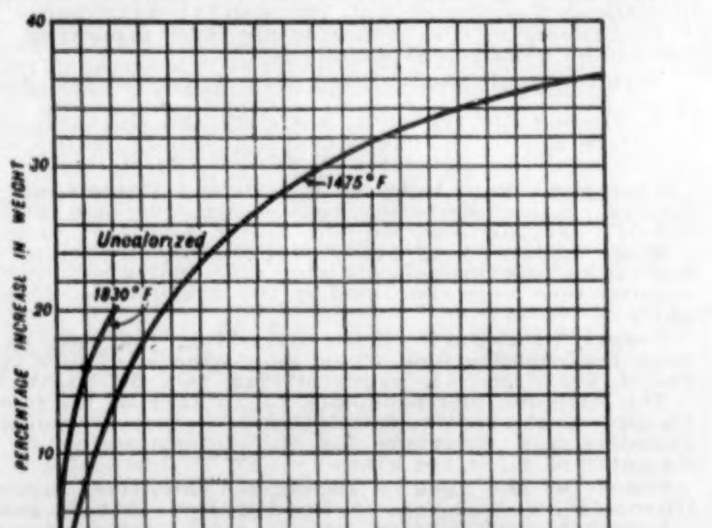
A short, concise review of the field of surface treatment is made, including both the mechanical and chemical methods. The surfaces may be covered by the effects of chemical treatment, by the use of paints and by metallic coatings. The variety of behavior and range of usefulness of each, as well as the possibilities for improvement and the necessity for coöperative research is discussed. MAB (8)

Aluminum and Its Alloys. *Electrician,* Vol. 106, May 29, 1931, page 782.

The principles of surface treatment by electrochemical methods and processes for various uses are discussed. The available methods of surface treatment may be divided broadly into 2 main categories (mechanical and chemical) with the latter subdivided into pure chemical, physicochemical and electrochemical. The treatments may serve as protection, decoration, or insulation. Various forms of anodic oxidation are outlined. Al presents special difficulties for electro-deposition, but the difficulty of non-adherent film can be overcome by: (1) coating the metal with a fast-adhering coating of a second metal (usually Cd or Zn); (2) working with a very big current; (3) rendering the metal passive. The last method is most commonly used. Some special methods are pointed out. An Al surface may be prepared for electrodeposition by electrolytic deposition of an amalgam. A suitable bath contains: 10 gm. zinc chloride, 5 gm. mercuric nitrate, 200 gm. caustic soda, 200 gm. sodamide, 40 gm. stannous chloride and 10 gm. caustic potash to 20 liters of water. The voltage is 1.5 and the time a few minutes. For Al plating, the bath must be well buffered, contain a suitable addition agent and have a definite pH value maintained. Ni, Cu, Cd and Zn are plated directly on Al and combinations of Cd-Cr, Ni-Cu-Ni or brass, Ag, Au, Pb, Co, etc., with an intermediate plating of one of the former metals, usually Ni or Cu. Ni is plated on a roughened surface; Cu, Cd and Zn on a smooth surface. Several baths for Ni plating solutions for Al are given, as well as for Zn and Cd. Soft rubber may be fixed directly to Al by vulcanization. Coloring, and coppering of Al, and blackening are touched upon. WHB (8)

Calorising. *Engineer,* Vol. 152, Aug. 7, 1931, page 139.

Brief discussion of the process of alloying the surface of steel with Al. A photomicrograph is given which shows the normal steel structure merging at the surface into an alloy with the Al and finally a thin film of aluminum oxide forming a protective coating on the outside. A graph is given showing the resistance of calorized steel as compared with untreated metal to scaling at high temperatures. LFM (8)



OXIDATION TESTS

The Surface Treatment of Aluminium and Its Alloys. *Metal Industry,* London, Vol. 38, May 29, 1931, pages 555-558; June 26, 1931, pages 649-651.

This is *Intelligence Memorandum* No. 16 of the *British Aluminum Company, Ltd.* A detailed description is given of the mechanical, chemical, and electrochemical methods of surface treatment of Al and its alloys for protective and decorative purposes. PRK (8)

Zinc Coating Protects Hudson River Bridge Cables. *Metal Industry,* N. Y., Vol. 29, May 1931, page 210.

Special apparatus was used to hot galvanize twice the 29,000 tons of wire, 0.192 in. in diameter, before it was "spun" into the bridge cable. PRK (8)

INDUSTRIAL USES & APPLICATIONS (9)

Lead in Form Of Continuous Mold Used in Curing Rubber. *American Metal Market*, Vol. 38, Apr. 8, 1931, page 3.
Reprint of same by James L. Cutler in *The Circle*, National Lead Co. Bulletin, Apr. 1931. DTR (9)

Honing Cylinder Blocks, Barnes Drill Co. *Abrasive Industry*, Vol. 12, Nov. 1931, page 30.
An all-geared, hydraulically operated honing machine is described and illustrated. It is designed especially for economical finishing of automobile engine cylinder blocks. WAT (9)

Aluminum-Alloy Motor Launch. *Engineering*, Vol. 131, Apr. 24, 1931, page 542.
Describes launch built by the Birmingham Aluminum Casting Company, using Birmabright Al alloy. This is a high-Al alloy containing some Mg but very little Si. It is highly corrosion-resistant and has excellent physical properties. When cast in sand, the alloy has a clean, bright finish and is free from porosity. LFM (9)

Alloy Steels Important in Valve Manufacture. A. H. Allen. *Iron Trade Review*, Vol. 86 Feb. 20, 1930, pages 39-42, 47.
Describes practice of Thompson Products Inc., Cleveland. Si-Cr steel containing 3-4%C and 7-10% Cr is used in automotive exhaust valves. Intake valves are made from a special steel, S.A.E. steel 3140, and a few from 6150. An austenitic steel known as C.N.S. steel, with a Cr content of 11-15%, Ni, 7-9%, and Si, 2-3%, is used for most aircraft exhaust valves. It is corrosion resistant, has high strength at heat and will not harden. S.A.E. 71360, a high W steel, is used for aircraft intake valves and some exhaust valves. A Co-Cr steel, PRK-33, is used for a few aircraft exhaust valves. It is heat resistant and has high tensile strength and good impact values. Outlines the various operations in the manufacture of valves. MS (9)

Cleveland's Results From Rail Wear Studies. Howard H. George, *Electric Traction*, Vol. 27, Nov. 1931, pages 540-541.
The use of intermediate manganese steel rails at car shops and other points of excessive wear by the Cleveland Railway Company has been justified through rail wear studies. The results show that the rate of vertical wear per 100,000 wheel passes between stops and at the stop are identical, a condition which is very desirous. No difficulty has been encountered in welding this material; both seam welds and Thermit welds have shown no breaks to date (since Aug. 1928). The company feels that the increase rail cost of 7½% has been well worth while. Composition of material not given. WAT (9)

Aluminum Foil as a Basis of Insulation. Max Breitung. *Refrigerating Engineer*, Vol. 22, July 1931, pages 11-14.
Al foil insulation is built up by applying successive layers of foil with spacings of approximately 1/3 in. The foil may be in flat sheets or crumpled to provide irregular surfaces. The foil used is about 0.0003 in. in thickness. Al foil insulation has the advantage of being very light in weight, weighing only 3 oz./ft.^{3} of insulation, while cork and magnesia weigh 10 lbs. and 17 lbs./ft.^{3}, respectively. As an insulation, the crumpled Al foil is equal to cork at low temperature and superior to magnesia at high temperature. Al foil operates as an insulant because of its high reflectivity for radiant heat, about 95% of the radiant heat being reflected. Long exposure of the foil to the atmosphere even at high temperature did not change the reflectivity. (9)

The Building Spandrel of Cast or Sheet Aluminum alloy. *Engineering News-Record*, Vol. 108, Feb. 11, 1932, pages 216-217.
Discussion of the manufacture and properties of cast aluminum ornamental spandrels. CBJ (9)

Welded Steel Tools. *Edgar Allen News*, Vol. 10, Jan. 1932, page 28.
In these tools the ends, not only the tips of high-speed steel are welded to shanks of a high-grade quality steel, for which method a considerable economy is claimed. Ha (9)

Cast Steel Foundations for Railroad Equipment. Wm. M. Sheehan. *Railway Mechanical Engineer*, Vol. 105, Dec. 1931, pages 573-577, 584; *Steel Founder*, Vol. 2, Jan.-Feb. 1932, pages 18-23.
Many parts of very bulky proportions, as bottoms of tender tanks, locomotive beds, etc., are illustrated. Problems of maintenance were simplified by the introduction of cast steel parts. Ha (9)

Copper Tubes in Domestic Plumbing. (Le tube en cuivre dans les canalisations d'eau domestiques.) *Cuivre et Laiton*, Vol. 4, 1931, Dec. 15, pages 543-549, Dec. 30, pages 567-574.
The hygienic and economic advantages of Cu pipes over Pb pipe in the water installation of houses are pointed out; formulas and diagrams for the determination of proper diameter of pipes are given. Ha (9)

Report of the Springs Research Committee. *Department of Scientific & Industrial Research*, London, Nov. 1931, 75 pages.
Research work was carried out with particular reference to properties of spring materials, design of springs, and method of suspension of vehicles. The points investigated were the best distribution of material in the spring and the stresses to be allowed in the material, the various methods of transmitting the driving torque and their effect on the spring, the methods of attachment of the spring to the chassis, the effect of nip on the safe stress to which the material could be subjected, the use of rebound plates, resilient stoppers, and reversed camber. The materials used, the test methods applied are described in detail; as a general conclusion it could be stated that all steels investigated can be treated so as to give very high intrinsic properties, yet these high properties are not realized in the spring material as ordinarily manufactured and used. This surprising discrepancy is due to the fact that, owing to development of surface weaknesses as the result of heat-treatment or other causes, the intrinsic properties are never fully realized either in spiral springs or in plates. The influence of the weak surface layer seems to be sufficient to nullify to a great extent the advantages gained by the use of properly treated high-grade spring steels. The general theory of designing springs is developed; appendices with bibliographies on springs and a list of published papers on research in this field is added. Ha (9)

Copper Roofs. (Les Toitures en Cuivre.) *Cuivre et Laiton*, Vol. 4, Nov. 30, 1931, pages 517-530.
The various types of roofs as employed for buildings and other edifices of a more formal character, their construction details and materials are described in detail; a solution for producing an artificial patina is given, and a number of important buildings with copper roofs in America and Europe enumerated. Ha (9)

Copper and Wine. (Le Cuivre et le Vin.) *Cuivre et Laiton*, Vol. 4, Dec. 15, 1931, pages 553-554.
The important part which copper has in the modern treatment of grapes and wine is pointed out; copper sulphate serves to destroy injurious insects. Copper apparatus and tubing are used in pressing, fermenting the juice, and treating the finished product. Ha (9)

Thallium. *Chemicals*, Vol. 36, Dec. 1931, page 25.
Sources, properties and uses of Th are given. Because of their high refracting power, Th compounds are used in the manufacture of certain kinds of optical glass. WAT (9)

Alloy 43 in Architecture. (Legierung 43 in der Architektur.) *Giesserei mit Giesserei-Zeitung*, Vol. 18, Nov. 13, 1931, page 882.
This is an Al-Si alloy of silver white color which can be cast very easily; it has a tensile strength of 14 kg./mm^2 and a very high resistance to corrosion. It is used particularly for ornaments, frames, window sashes and sills, etc., for architectural purposes. Ha (9)

Bomb of Chrome-Nickel Steel withstands High-Pressure. *Steel*, Vol. 89, Aug. 27, 1931, page 33.
In an oil cracking process, bombs are used for heating a heavy crude oil to 850°-950° F. for the extraction of commercial gasoline. The bomb is of forged chrome-nickel steel and withstands a pressure of 1000 lbs. Ha (9)

Mirrors and Reflectors. *Metal Progress*, Vol. 19, May 1931, pages 92-96.
Description of silvering methods and the history of mirror making. WLC (9)

Nickel Cast Iron in the Automobile Industry. *Foundry Trade Journal*, Vol. 45, Oct. 29, 1931, pages 267-271.
An article, accompanied by 8 figures and 1 table, showing suggested compositions of castings for the automobile industry. A brief discussion is introduced of the value of nickel (1) in equalizing the structure and thus minimizing the variations between thick and thin sections in a casting, (2) in improving machinability, (3) in refining and condensing the iron in thick sections, (4) in eliminating porosity, (5) in inducing heat- and corrosion-resistant properties when present in sufficiently high proportions together with other elements, (6) in improving resistance to wear and abrasion, (7) in giving to iron qualities which make it capable of improvement by heat treatment, and (8) in producing high expansion castings to work in conjunction with aluminum alloys. This is followed by a description of numerous instances where nickel cast iron has proved of value in the automobile industry. OWE (9)

Aluminum Cable Specified. *American Metal Market*, Vol. 38, Apr. 1, 1931, page 14.
Reprinted from *Metal Bulletin*, London. Total of 12,000 miles steel-cored Al cables and earth wire specified for main lines, or total of 8,500 tons. Equal quantity of secondary low voltage lines. DTR (9)

Hafnium Has Few Uses. *American Metal Market*, Vol. 38, May 28, 1931, page 5.
Reprinted from *U. S. Bureau of Mines Information Circular* 6457, "Hafnium." High melting point and electronic emissivity to be used in radio tubes and incandescent electric lamp filaments, and for cathode surfaces of X-ray tubes and rectifiers. DTR (9)

Platinum Has No Substitutes For Many Of Its Uses. *American Metal Market*, Vol. 38, Apr. 8, 1931, pages 2-3.
Reprinted from *Information Circular* 6389, "Platinum," *U. S. Bureau of Mines*. Covers entire scope of uses of Pt and allied metals. Some substitutes in electrical industry for Pt, and in surgical dental instruments Pt replaced by Stellite and other alloys of Cr, W, and Co. DTR (9)

New Ways in Building Pipe Lines (Neue Wege im Rohrleitungsbau). H. Juergens. *Autogene Metallbearbeitung*, Vol. 24, Oct. 1, 1931, pages 291-293.
Notes the advantages offered by welding and cutting in the building of gas lines and water lines for building up new city districts and settlements. A comparison of costs shows considerable savings against other methods. Ha (9)

Pipe Line Review Notes. W. S. Johnston. *American Gas Journal*, Vol. 136, Feb. 1932, page 31-32.
More than 9000 miles of natural gas lines were laid in 1931 costing approximately $450,000,000. The largest line, 975 miles long, cost on an average of $75,000 per mile. 220,000 tons of 24-inch diameter steel pipe were used. Line crosses portions of the states of Texas, Oklahoma, Kansas, Nebraska, Iowa and Illinois. Pipe was welded and used sleeve couplings at pre-determined intervals to provide for expansion. Exterior of pipe was coated with non-corrosive paint. In some soil conditions the pipe was wrapped with especially impregnated felt and then sealed with hot asphalt. CBJ (9)

Automobile Body Sheets; Properties of Steel for Body Building. R. O. Griffis. *S. A. E. Journal*, Vol. 30, Jan. 1932, pages 27-28.
The requirements of sheets for producing automobile bodies are that they can be formed without breaking, necking down, wrinkling or buckling, and that the surface of the finished part shall be free from defects which would cause excessive finishing costs. Automobile body sheets are made today by 3 principal methods: the hand-operated mill, the continuous hot-mill practice, and the continuous cold-mill process, working either on coils or single sheets. Methods for testing the quality of the sheet are described. The factors which are at present beyond the absolute control of the sheet manufacturer are ingot segregation, slight chemical variations between different heats of steel, unavoidable variations in normalizing temperatures or cooling rates, and variations in items like gage and surface conditions. Suggestions for coöperation of shops are offered. Ha (9)

HEAT TREATMENT (10)

Improved Equipment Facilitates Heat Treatment of Bolts. A. H. Allen. *Steel,* Vol. 88, Feb. 26, 1931, pages 31-34.

A rather complete account of the modern heat treating department in the bolt and nut plant of the Lamson and Sessions Co., Cleveland, Ohio. JN (10)

A Contribution to the Question of Inner Stresses in Steel due to Heat Treatment. (Beitrag zur Frage der Eigenspannungen im Stahl durch Wärmebehandlung.) Hans Bühler. *Mitteilungen aus dem Forschungs-Institut der Vereinigte Stahlwerke Aktiengesellschaft Dortmund,* Vol. 2, No. 8, 1931, pages 149-192; *Archiv für Eisenhüttenwesen,* Vol. 5, Feb. 1932, pages 413-418.

The concept of "inner stresses" is defined as that state which is produced in a body in any manner without the effect of an exterior force. Inner stresses occur as soon as non-uniform changes of volume or shape occur in a body over its section. These changes can be of chemical origin, a consequence of non-uniform chemical composition; of mechanical origin as consequence of forging, rolling, drawing, etc., of thermal origin as heating or cooling stresses; of physico-chemical origin as consequence of a transformation of structure with change of volume. The last two are the principal causes in the heat treatment of steel and are thoroughly investigated. From the test results, for the details of which the paper must be referred to, it follows that pure heat stresses caused by water quenching of C steels below temperatures of point A_1, increase gradually up to 450° C. then considerably. Tangential stresses have a similar course as the longitudinal stresses. Inner stresses can be removed almost entirely by annealing; up to 300° C. they are reduced considerably, and by annealing up to 600° C. also the maximum stresses are reduced to less than 10 kg./mm.^{2} Numerous diagrams and curves illustrate the test results and a list of 9 bibliographic references is added. Heating and Treating Locomotive Forgings. *Metal Progress,* Vol. 19, Apr. 1931, pages 45-48.

A release of the Recommended Practice Committee A.S.S.T. gives the recommended methods of heating for forging, forging annealing, normalizing and tempering. Times and temperatures for various steels and sizes are recommended. WLC (10)

Decarburizing Action of Fused Salt Bath. A. Seuthe & E. Schulz. *Iron Age,* Vol. 128, Dec. 17, 1931, page 1554.

An abstract translation of an article in *Stahl und Eisen,* Vol. 51, June 25, 1931. See *Metals & Alloys,* Vol. 3, Jan. 1932, page MA 13. VSP (10)

Difficulties of Heat Treating Tubular Axles are Overcome by Special Design of Normalizing and Hardening Furnace. I. W. Spring (Logan Gear Co.). *Automotive Industries,* Vol. 65, Aug. 1931, pages 241, 244; *American Gas Journal,* Vol. 135, Sept. 1931, pages 56-57.

Special furnace is continuous-chain-conveyor type, gas fired, with capacity of 50 axles/hr, from cold to normalizing temperature of 1650° F. and hardening temperature of 1470° F. Normalizing furnace inside 13 ft., hardening unit 9 ft., and cooling chamber between units 6 ft. long. Description of normalizing, hardening, quenching, pickling and drawing is given. CBJ+DTR (10)

Heat Treatment of Small Tools with Modern Equipment and Technique. David A. Nemser (Pratt & Whitney Co.). *Metal Progress,* Vol. 21, Feb. 1932, pages 23-28.

Considerable advance has been made in recent years in the control of the art of hardening both by furnace manufacturers and metallurgists. The determination of the physical requirements of the tool material and the selection of commercial steels is followed by study of the ability to duplicate quality in mass production and facilities necessary. The author amplifies the statement that cost of such facilities is secondary to their efficiency. Furnaces for the treatment of small tools of water hardening tool steel, oil hardening tool steel, and high speed tool steel are described. Considerable space is devoted to the treatment of high speed steel and furnaces used. Tongs and other fixtures to facilitate quality and uniformity of work are discussed. Surface finishing of tools and inspection methods are described. WLC (10)

Decarburization of Steel at Heat-Treating Temperatures. *Gas Journal,* Vol. 195, July 15, 1931, page 149.

Reviews the Bulletin put out by the Department of Engineering Research of the University of Michigan under the auspices of the Committee on Industrial Gas Research of the American Gas Association in 1928 for a remedy for the decarburization of steel in certain hardening operations in which the maximum surface hardness is required. The paper is written by W. E. Jominy, who points out that decarburization has often been the cause of excessive wear and the early failure of parts in practice. The influence of gases found in the products of combustion of manufactured gas, the effect of changes of pressure, of rate of flow of the gases, and of the atmosphere were investigated. H has the strongest decarburizing action of gases in an open-fired furnace. Carbon dioxide is the second most serious gas. N, if absolutely pure, causes no decarburization, though ordinary nitrogen does. Steam causes a very small amount after 5 hours' heating at 1450° F. and air has very little under the same conditions. Variations in pressure from ½ to 1½ atmospheres have practically no effect on decarburization. The stronger the oxidizing furnace atmosphere as measured by the percentage of free O, the less the tendency to carburize, and conversely. Elimination of decarburization and of scaling can be accomplished by heating in pure N. 3 main methods are given: (a) heating in a so-called neutral or slightly oxidizing furnace atmosphere; (b) a hypereutectoid case will minimize softness if the steel has been carburized; (c) formation of certain types of scale on the surface will prevent decarburization. Short periods of exposure may be used to minimize the decarburizing effects. Steels of certain composition may decarburize more rapidly than others. MAB (10)

Case Hardening & Nitrogen Hardening (10c)

Temperature Control a Feature of New Nitriding Furnace. James H. Knapp. *Steel,* Vol. 88, Feb. 19, 1931, pages 38, 40.

Describes new type of gas-fired furnace, the Convecto, especially adapted for continued low temperature operation. The temperature of the furnace is kept below the flame temperature of the fuel by means of a regulated stream of cold air which mixes with the gases of combustion around the flame. Also, a uniform and rapid circulation of hot gases is maintained throughout the furnace chamber. It is claimed that this furnace can be operated satisfactorily between 300° and 1200° F. with close temperature regulation and uniform heat distribution. JN (10c)

New Carburizing Bath Affords Increase in Depth of Case. E. C. Moffett. *Steel,* Vol. 88, Mar. 12, 1931, pages 38-42.

The usual sodium cyanide bath gives a case of about 0.01 in. thickness. By adding an activating ingredient, calcium cyanide, cases from 0.005 to 0.032 in. at carburizing temperatures of 1650° to 1700 ° F. can be produced in 3 hours. The procedure is described more in detail and curves showing the improvement produced. Ha (10c)

Hardness Induced by Nitriding. Marcus A. Grossmann. *Foundry Trade Journal,* Vol. 45, Oct. 22, 1931, page 259.

Extended abstract of paper which was read at a meeting of the American Iron & Steel Institute. See "An Appraisal of Nitriding," *Metals & Alloys,* Vol. 2, Nov. 1931, page 264. OWE (10c)

Is the Carburizing Process a Success? E. F. Lake. *Heat Treating & Forging,* Vol. 17, May 1931, pages 455-459.

The author believes that frequently properly heat-treated alloyed steels give better service and even make a saving in material for parts under heavy fatigue stresses possible. The carburizing process often does not give uniformity of grain and causes inner stresses leading to microscopic cracks. Ha (10c)

Influence of High Frequency Electrical Oscillations on the Properties of Metals and Alloys. Julius Grant. *Metal Industry, London,* Vol. 39, Aug. 28, 1931, page 205.

The diffusion of chromium and of carbon in iron is speeded up by the high frequency vibrations set up by electromagnetic oscillations. The degree of nitriding hardness can also be increased. PRK (10c)

Quenching (10d)

An Investigation of Martensitic Quenching and a Hardening Thermal Treatment for Cast Irons (Recherches sur la trempe martensitique et le traitement thermique durcissant des fontes). Leon Guillet, Jean Galibourg & Marcel Ballay. *Revue de Métallurgie,* Vol. 28, Nov. 1931, pages 581-597.

The advantages of white cast iron castings can be fully realized when castings leave the mold in martensitic state, softened for machining by a proper treatment and rehardened again by some very mild treatment which will not introduce any cracking. The same results can be obtained using gray iron to which some alloying elements are added and which is heat treated after machining. The present paper is the result of a very extensive investigation dealing largely with the influence of Ni addition on hardening properties of cast iron. Critical points, necessary quenching rates and physical properties after heat treatment of several hundred different irons were determined. Quenching decreases all mechanical characteristics with exception of hardness, but drawing after it increases shear resistance by about 50% and bending value by 10%. In selection of the desired composition, one must have a gray iron, which, the carbon content being given, specifies the minimum amount of Si. Quenching tendency is obtained by addition of Ni. Its amount depends on the permissible cooling speed. For oil quenching, 1.5-2% are sufficient. For air quenching, 4 or 5% are required, depending on the thickness of the casting. In the majority of cases Si can be around 1%. The paper is illustrated with 41 curves and tables and 11 photomicrographs. JDG (10d)

Effect of the Quenching Temperature on the Physical Properties of KA2S. John L. Everhart. *Wire & Wire Products,* Vol. 7, Jan. 1932, pages 5-7.

The tests were made with the stainless steel KA2S of the composition 0.065% C, 0.54% Si, 16.96% Cr, and 8.93% Ni. The samples were heated up to different temperatures and quenched in cold water. The following table shows the results:

Quenching Temp. °F	Hardness Rockwell	Yield Point lbs./in.^{2}	Tensile Strength lbs./in.^{2}	Elong. % in 2"	Reduction of Area %
1850	B-74	28,000	94,000	62	75
1950	B-78	29,500	95,000	60	72
2050	B-78	30,000	96,000	58	71
2150	B-73	27,000	89,500	62	68
2300	B-70	25,500	84,000	66	72

The results indicate that although the heat treatment of the austenitic alloys is a very simple process as compared with some other alloys, the quenching temperature is a very important factor in obtaining suitable physical properties and grain size. Ha (10d)

Does Quenching Stiffen a Spring? *Metal Progress,* Vol. 18, Dec. 1930, pages 90, 116.

A discussion by A. L. Boegehold, (General Motors, Detroit) and F. P. Zimmerli, (Barnes, Gibson-Raymond, Inc., Detroit) of an editorial article in Oct. *Metal Progress,* regarding the effect of quenching after coiling heat treated wire into a spring. WLC (10d)

Quenching Cracks (Les tapures de trempe). A. Sourdillon. *Revue de Métallurgie,* Vol. 28, Nov. 1931, pages 631-638.

A summary of the well known factors leading to cracking of steel on quenching. Recommendation is made to replace, where possible, high carbon steels with alloy steels containing less carbon. For important parts, the use of plain carbon steel requiring a water quench should be avoided. JDG (10d)

Drawing (10e)

A Contribution to the Study of Tempering Quenched Steels. (Contribution a l'etude du revenu des aciers trempes.) Pierre Chevenard & Albert Portevin. *Revue de Métallurgie*, Vol. 28, Aug. 1931, pages 417-425; Sept. 1931, pages 503-517; Oct. 1931, pages 546-556; *Revue Universelle des Mines*, Series 8, Vol. 6, Nov. 15, 1931, pages 309-315; Dec. 1, pages 391-400; Dec. 15, 1931, pages 443-448.

All complex changes occurring in a metal during thermal treatment can be detected and accurately estimated only by thermo-physical methods. Dilatometer records the weakest and slowest reactions on the diagrams which are easy of interpretation because the aggregates obey the laws of mixtures. 12 steels were investigated dilatometrically, separating the heating and cooling periods by a 7-hr. interval at a constant temperature. The results were checked magnetometrically and under a microscope. High C alloy steels quenched to a fully austenitic state were used as samples with a few exceptions. In Mn steel (1.5% C, 2.05% Mn) the decomposition of austenite occurs in 2 stages: (1) austenite into cementite and less carburized austenite (2) partially decarburized austenite into cementite and α iron. The decomposition of martensite is slower and is accompanied by variations in the distribution of Mn in cementite and α iron segregating in the former. In a Cr steel heated under 330° C., precipitation of cementite with the low Curie point, transformation of γ into α iron and the precipitation of cementite with a high Curie point are observed. The precipitation of proeutectoid cementite preceding or accompanying the formation of troostite is very sharp here. The decomposition of martensite is completed at 350° C. Above 330° C., the precipitation of carbides is faster than the formation of troostite. At the end of the heating interval the austenite which remains undecomposed becomes more abundant and contains less C and Cr, the higher was the temperature of isothermic heating so that, deprived from the stabilizing action of these elements, it cannot return to the room temperature without some profound changes. Cooled from this range, the steel becomes quenched with the formation of secondary martensite. Dilatometer shows it clearly. With 1.25% C and 4.8% Cr, the phenomena are the same as for lower C-Cr steel but are much sharper. On its hardness curve there are 3 distinct maxima at 300°, 400° and 475° C. corresponding to the formation of troostite, precipitation of cementite from austenite and secondary quenching. Quenched from 1180° C., a 1.60% C steel forms a mixture of equal amounts of austenite and martensite. The latter appears after an acid etch as bright needles. From the room temperature to about 150° C. martensite decomposes forming finely divided cementite and martensite less rich in C. This increases its solubility and after an acid etch the martensite appears now as dark needles. From 150° C. upwards the decomposition of austenite into proeutectoid cementite and troostite (a mixture of martensite and cementite) becomes more and more rapid and partially decomposed austenite becomes more corrodible so that acid etch darkens it while leaving martensitic needles bright again. Above 245° C., no more γ iron is present. The steel consists then of 3 martensites: the original, the one formed on decomposition of austenite and martensite of troostite. They all lose their C progressively tending towards sorbite, a mixture of α iron and cementite. To this reaction must be added structural changes such as coalescence of cementite, etc. Drawing above 550° C. causes in this steel the dissociation of cementite into graphite and ferrite. In drawing a quenched 0.8% C steel, the decomposition of austenite is slight and changes in martensite are pronounced. The transformation of austenite into troostite is completed here at 225° C. The rapid increase in hardness at 75° C. is not due here to the decomposition of austenite, which is practically unaffected under 100° C. but to the precipitation of cementite from martensite. Freed from the secondary phenomena of austenite decomposition, the mechanism of martensite decomposition consists in progressive decarburization of α Fe-C solution taking place over a wide temperature range. 72 graphs and 11 photomicrographs are given.

Aging (10f)

Age-Hardening of Titanium-Copper Alloys. (Vergütbare Titan-Kupferlegierungen.) W. Kroll. *Zeitschrift für Metallkunde*, Vol. 23, Jan. 1931, pages 33-34.

Cu-Ti alloys can be melted in air up to 3% Ti, but greater Ti-content leads to formation of titanium nitride. With air excluded (argon) forgeable alloys can be prepared with Ti as high as 6%. A (t-x) constitutional diagram is given up to 25% Ti in which the liquidus and solidus have been experimentally determined. The solid solubility curve is approximated: at 900° C. (the eutectic temp.) the solid solubility is probably 3-4% Ti, at room temperature the solubility is less than 0.56% Ti since this alloy ages. Curves are given for Brinell hardness and tensile strength of Cu-Ti alloys up to 4% Ti immediately after quenching from 850° C. and after 24 hrs. aging at 350° C. In the quenched 3% Ti alloy, the Brinell hardness is 85 and the tensile strength 45 kg./mm.^{2} as compared to 52 and 32 kg./mm.^{2} for pure Cu; aging for 24 hrs. at 850° C. increases these values to 200 and 72 kg./mm.^{2}. Curves are given showing changes in electrical conductivity of alloys up to 3% Ti as a function of aging treatment.
